3.7.2 Amortised cost financial liabilities with contractual linkage features

Another complex area is the accounting for a financial liability in a securitisation structure where a special purpose entity (SPE) invests in a portfolio of loans and raises funds by issuing listed non-recourse notes to investors. The SPE's contractual obligations on the listed notes are linked to the performance of the loans less the interest spread. This contractual linkage feature, where any losses suffered on the loans will be borne by the noteholders, will be accounted for as part of the listed notes liability. Consequently, the EIR of the notes will reflect an estimate of any expected cash shortfalls arising from credit losses on the underlying loan assets (since this affects the contractual payments required on the notes). [IFRS 9.BCZ5.67].

With regards to how the expected cash flows are estimated when calculating EIR, IFRS 9 does not contain clear guidance. Consequently, the EIR should be determined by estimating what the resultant cashflows will be. This may involve the use of judgement or assumptions based on the latest available, reliable information. [IAS 8.32]. The expected cash flows could be estimated using the most likely outcome method or a probability-weighted approach. In determining which estimation technique to use (i.e., the most likely outcome or a probability-weighted method), an entity could consider the principles in IAS 37 for determining a best estimate, see Chapter 27, as well as the principles in IFRIC 23 which requires an entity to use whichever method better predicts the resolution of the uncertainty, see Chapter 29. The estimation technique used should remain consistent, unless there are changes in the circumstances on which the accounting estimate was based or as a result of new information, new developments or more experience. [IAS 8.34]. Any revisions to the estimated contractual cash payments on the listed notes due to the linkage feature should be accounted for as an adjustment to the amortised cost of the noteholder liability (discounted at the original effective interest rate) and recognised in profit or loss (for more details, see Chapter 47). [IFRS 9.B5.4.6].

3.7.3 Amortised cost financial liabilities with contingent demand features

As discussed in section 3.4 above, the definition of effective interest rate makes it clear that entities are required to take prepayment, call and similar options into account when determining the EIR of a financial instrument. There are situations where the ability to exercise these options may be contingent on some future event. The Illustration below shows how an entity may need to revise its estimate of payments in the event that an entity breaches a debt covenant and the loan becomes repayable on demand.

Illustration 3-11: Loan repayable on demand due to breach of a covenant

Entity X (the borrower) borrows CU1,000 from Bank Y (the lender) at the beginning of 20X1. The loan attracts interest at a floating rate and is repayable in five years' time (i.e., at the end of 20X5). The borrower incurs transaction costs amounting to CU50. In the event that there is a breach of covenant, the financial liability becomes repayable on demand at the option of the lender.

Key assumptions:

- The loan is measured at amortised cost.
- At the end of the reporting period 20X3, Entity X has breached its debt covenant.
- The value of unamortised transaction costs at the end of 20X3 is CU20.

Analysis:

The loan contract provides Bank Y (the lender) with an option to demand repayment of the loan in the event that Entity X (the borrower) breaches a covenant. In determining the period over which the transaction costs should be amortised, Entity X would have had to assess the probability of the early repayment option being triggered and exercised at initial recognition. This would require an assessment of:

- a) The likelihood of the option becoming exercisable (taking into account the probability of Entity X breaching covenants).

And

- b) The likelihood of the bank exercising its option in that instance.

This estimate could be determined using a most likely outcome approach or a probability-weighted approach, depending on the specific facts and circumstances. Any subsequent revision of the estimates of cash flows would need to be accounted for in accordance with IFRS 9.B5.4.6.

As a result of Entity X breaching its covenant at the end of 20X3 and the liability becoming repayable on demand at the option of the Bank Y, Entity X, as part of its re-estimation of the cash flows, would need to update its assessment of whether the bank is expected to exercise its option to demand repayment. The period over which the transaction costs are to be amortised would need to be updated accordingly. The gross carrying amount of the financial liability would need to be updated for any change in such estimate, with any consequential adjustment being recognised in profit or loss. [IFRS 9.B5.4.6]. In some cases, the entity may not have sufficient information to determine whether the lender will demand repayment of the loan, in which case it may be appropriate to accelerate the amortisation of the remaining unamortised transaction costs.

The assumptions that the borrower makes regarding whether the bank will demand repayment, should be consistent with the assumptions used for assessing the entity's ability to continue as a going concern.

How we see it

In the Illustration above, the loan (financial liability) is measured initially at fair value and subsequently at amortised cost. If the loan was subsequently measured at fair value, then the entity would have to consider IFRS 13.47 which requires that the fair value of a financial liability with a demand feature, is not less than the amount payable on demand, discounted from the first date that the amount could be required to be paid. However, as illustrated above, where a loan that is subsequently measured at amortised cost becomes repayable on demand at some point after initial recognition, e.g., as result of a covenant breach, then the principles of IFRS 13.47 would not be applicable. Therefore, the amortisation of the remaining unamortised transaction costs would not necessarily need to be accelerated such that the loan reflects the amount that could be demanded by the bank. Rather in such a case, same as before the covenant breach, the amortised cost loan would need to be remeasured taking into account the entity's revised estimate of cash flows. This estimate would involve the use of judgement or assumptions based on the latest available, reliable information, including the status of negotiations with the bank and how this impacts the probability and timing of the bank demanding repayment.

The Illustration above explains how an entity needs to revise its estimate of the timing of cash flows in the event of breaching a covenant, and the loan becoming repayable on demand. In determining which estimation technique to use (i.e., the most likely outcome or a probability-weighted method), an entity could consider the principles in IAS 37 for determining a best estimate, see Chapter 27, as well as the principles in IFRIC 23 which requires an entity to use whichever method better predicts the resolution of the uncertainty, see Chapter 29.

An entity would also need to update its liquidity risk disclosures in response to the loan becoming repayable on demand. Refer to Chapter 50 for further information. The assessment of whether the liability should be presented in the statement of financial position (as either current or non-current) is separate from the measurement considerations. In the above Illustration given that the breach occurred prior to the end of the reporting period, and there was no renegotiation of the terms of the loan that were concluded by period end, the loan would be classified as current. This would be the case regardless of whether the entity expects the bank to demand repayment or whether there is an expectation that the terms of the loan will be renegotiated. Refer to Chapter 3 for further information.

3.8 Modified financial assets and liabilities

3.8.1 Accounting for modifications that do not result in derecognition

When the contractual cash flows of a financial asset are renegotiated or otherwise modified and the renegotiation or modification does not result in the derecognition of that financial asset (see Chapter 48), an entity recalculates the gross carrying amount of the financial asset and recognises a modification gain or loss in profit or loss. The gross carrying amount of the financial asset is recalculated as the present value of the renegotiated or modified contractual cash flows that are discounted at the financial asset's original effective interest rate (or credit-adjusted effective interest rate for purchased or originated credit-impaired financial assets - see section 3.1.2 above). Any costs or fees incurred adjust the carrying amount of the modified financial asset and are amortised over the remaining term of the modified financial asset (see section 3.8.2 below). [IFRS 9.5.4.3]. This results in a revision of the original EIR (see section 3.8.2 below).

The accounting for modifications of financial assets that do not result in derecognition is similar to changes in estimates (see section 3.4.1 above), i.e., the original EIR is retained and there is a catch-up adjustment to profit or loss for the change in expected cash flows discounted at the original EIR. [IFRS 9.B5.4.6]. For example, this would be applicable where a borrower is granted a concession to delay interest payments if the entity concludes that the change in the terms is not a substantial modification and therefore does not result in the derecognition of the original loan and the recognition of a new loan.

In October 2017, the Board added wording to the Basis for Conclusions of IFRS 9 as part of the amendment for prepayment features with negative compensation (see Chapter 44). This addition states that the requirements in IFRS 9 for adjusting the amortised cost of a financial liability when a modification (or exchange) does not result in the derecognition of the financial liability are consistent with the requirements for adjusting the gross carrying amount of a financial asset when a modification does not result in the derecognition of the financial asset. It adds that the requirements in IFRS 9 therefore provide an adequate basis for an entity to account for modifications and exchanges of financial liabilities that do not result in derecognition. [IFRS 9.BC4.252, IFRS 9.BC4.253]. Therefore IFRS 9 requires modifications of financial liabilities that do not result in derecognition to be accounted for similarly to modifications of financial assets. The amortised cost of the financial liability should be recalculated by computing the present value of estimated future contractual cash flows that are discounted at the financial instrument's original EIR. Any consequent adjustment should be recognised immediately in profit or loss. Any costs or fees incurred adjust the carrying amount of the liability and are amortised over the remaining term of the modified liability. [IFRS 9.B3.3.6]. This results in a revision of the original EIR (see section 3.8.2 below for more details on the treatment of modification fees, and the examples in Chapter 48).

In certain instances judgement may need to be applied to identify whether the substance of a payment made by a borrower to the lender represents additional interest or payment of principal to be accounted for as a modification of cash flows (in line with IFRS 9.BC4.253) rather than a transaction cost (in line with IFRS 9.B3.3.6) (see also Chapter 48).

When the terms of a financial instrument are amended, application of the standard's guidance on modifications raises questions as to what the 'original effective interest rate' actually means, in particular when the original contractual terms introduce some form of variability in the rate. This has led to more general questions about when it may be appropriate to apply a prospective change to the effective interest rate in accordance with IFRS 9.B5.4.5, assuming the effective interest rate has a variable component, rather than applying a fixed effective interest rate. The following Illustrations focus on whether the changes in terms constitute a modification or whether it may be appropriate to apply IFRS 9.B5.4.5. The accounting treatment is clear in some of the fact patterns whilst an element of interpretation is required in others. These Illustrations address the accounting from the lender's perspective but are applicable to both financial assets and financial liabilities, since the same modification requirements apply to both, as discussed above.

Illustration 3-12: Changes in credit spread**Fact Pattern 1: A ratchet loan with a rate reset**

Bank A issues a ratchet loan whereby the credit spread is increased in accordance with a scale of predetermined rates, on the occurrence of one or more predetermined events that are linked to the borrower's financial covenants (e.g., debt and equity or interest coverage ratios). These clauses are included to avoid the need to renegotiate the loan when the credit risk of the borrower changes and are considered to meet the standard's requirements for the loan to be recorded at amortised cost for the holder.

Analysis:

The credit spread is reset to reflect changes in credit risk and credit spreads are a component of a market interest rate as indicated by the January 2016 IFRS IC agenda decision (see section 3.1 above). Consequently, it would be appropriate to apply the guidance in B5.4.5. and account for the changes in the EIR prospectively on an accrual basis. [IFRS 9.B5.4.5].

How we see it

For a vanilla floating rate loan (e.g., at EURIBOR plus 2%), it is widely accepted that resetting only the benchmark component of the rate would be regarded as a change in EIR in accordance with IFRS 9.B5.4.5. Similarly, in our view, resetting only the credit spread component when the reset is predetermined at inception can be regarded as a change in EIR as it is considered a component of the market interest rate. Although the amount of the reset is specified at inception rather than being the market credit spread at the reset date, this may be accounted for as a reset of the EIR provided that the predetermined rate changes reasonably approximate the market rates for the different credit qualities as observed at inception.

Fact Pattern 2: Renegotiation of loan covenant in return for a higher credit spread

Company B has a term loan which pays interest at EURIBOR plus 2% (assume the EIR is also EURIBOR plus 2% as there were no transaction costs, fees, discount nor premium). Company B is close to breaching a covenant, and as they would generally be unable to prepay in the case of a covenant breach, they renegotiate the loan to adjust the covenant in return for increasing the credit spread applied to the loan to 3%. The revised credit spread reflects the amended terms of the loan and Company B's current credit risk.

Analysis:

The change in rate results solely from a renegotiation of the terms and this change was not specified in the contract at inception. Unless it was specified in the original terms that the credit spread would be reset to predetermined rates based on specific events, the change should be treated as a modification in accordance with IFRS 9.5.4.3. This would mean retaining the original EIR of EURIBOR plus 2%, resulting in the computation and recognition of a gain or loss based on the change of spread discounted at this rate. [IFRS 9.5.4.3].

Illustration 3-13: Modification - troubled debt restructuring

Company B enters into a fixed rate term loan. A few years later, the company is in financial difficulty and renegotiates with the lender to reduce or defer some of the payments due under the loan. The changes in the terms of the loan are not considered to result in a substantial modification and therefore it is not appropriate to derecognise the entire loan. This renegotiation is also not treated as a partial derecognition (see Chapter 48).

Analysis:

As the changes to the payments are not as a result of movements in market interest rates and this change was not specified in the contract at inception, it should be treated as a modification in accordance with IFRS 9.5.4.3. This would mean retaining the original fixed rate EIR, resulting in the computation and recognition of a gain or loss based on the change in the contractual payments discounted at this rate. [IFRS 9.5.4.3].

Illustration 3-14: Modification - renegotiation of a fixed rate loan**Fact pattern 1: Renegotiation of a non-prepayable fixed rate loan with a partial rate reset**

Company C has had a fixed-rate loan for several years, during which time the market interest rate has fallen. The terms of the loan do not include any ability for the company to prepay. Company C renegotiates the loan with the bank, to reduce the future interest payments to reflect a partial reset of the benchmark rate component of the rate. There has been no change in the credit risk or credit spread applicable to the loan and there are no other changes to the terms.

Analysis:

The change in rate results solely from a renegotiation of the terms and there was no existing prepayment option that would allow Company C to prepay and re-enter into a new loan with the revised rate. Consequently, the change should be treated as a modification in accordance with IFRS 9.5.4.3. This would mean retaining the original fixed rate EIR, resulting in the computation and recognition of a gain or loss based on the change in rate discounted at the original fixed EIR. [IFRS 9.5.4.3].

Fact pattern 2: Renegotiation of fixed rate loan that is prepayable at par to a current market rate

Company D has a fixed rate loan that is prepayable at par, i.e., for unpaid principal and interest,¹¹ at any time with no penalty. Company D renegotiates the terms of the loan with the lender to a new fixed market rate of interest. The renegotiation is assumed not to be considered a substantial modification.

How we see it

The standard is unclear on how to treat this fact pattern. In such circumstances, in our view, the lender may apply its judgement and select an appropriate accounting policy as shown in the analysis below.

Analysis:

Derecognition: The revision of the rate is in substance a settlement of the existing loan through the exercise of the prepayment option and commencement of a new loan at the market rate of interest. The cash flows of the original loan are deemed to have expired and should be derecognised with a corresponding new loan recognised at fair value on initial recognition. [IFRS 9.3.2.3].

Modification - keeping the original EIR: The revision does not represent an expiry of the contractual cash flows and there was no actual prepayment of the loan. Since the rate reset is not specifically detailed in the contract at inception, the prepayment option is not viewed as a reset option. Accordingly, the revision is treated as a modification in accordance with IFRS 9.5.4.3. This would mean retaining the original fixed rate EIR, resulting in the computation and recognition of a gain or loss based on the change of rate discounted at the original fixed EIR. [IFRS 9.5.4.3].

Modification - prospective change in EIR: The loan with a prepayment option at par with no penalty is considered analogous to a loan with an option to reset the interest rate to the then prevailing market rate. With such a prepayment option, Company D may prepay the fixed rate loan when interest rates decrease and refinance at a market rate of interest with the same or different lender, or force the same lender to renegotiate the existing interest rate to a market rate of interest. In both cases, the current lender is not entitled to receive the original fixed-rate over the full maturity of the loan. Accordingly, although the renegotiation is treated as a modification, the EIR is adjusted to reflect the new fixed market rate.

Fact pattern 3: Renegotiation of a fixed rate loan that is prepayable with compensation for the change in benchmark interest rate

Company E has a prepayable fixed-rate loan whereby the prepayment amount includes reasonable additional compensation to compensate for the change in benchmark interest rates. The prepayment clause is considered to meet the standard's requirements for the loan to be recorded at amortised cost. Company E renegotiates the terms of the loan with the lender to a new fixed market rate of interest. The renegotiation is assumed not to be considered as a substantial modification.

How we see it

The standard is unclear on how to treat this fact pattern. In such circumstances, in our view the lender may apply its judgement and select an appropriate accounting policy, as shown in the analysis below.

11 This assumes that the loan was not purchased or originated at a premium or discount.

Analysis:

Derecognition: The revision of the rate is in substance a settlement of the existing loan through the exercise of the prepayment option to prepay at fair value and commencement of a new loan at the market rate of interest. The cash flows of the original loan are deemed to have expired and should be derecognised with a corresponding new loan recognised at fair value on initial recognition.

Modification - keeping the original EIR: The revision does not represent an expiry of the contractual cash flows and there was no actual prepayment of the loan. In addition, the rate reset is not specifically detailed in the contract at inception and the prepayment amount requires compensation for the change in rates which differs from Fact pattern 2 above whereby it prepays at par with no penalty. Consequently, the loan cannot be analogised to a loan with an option to reset the interest rate to the then prevailing market rate. The revision should therefore be treated as a modification in accordance with IFRS 9.5.4.3. This would mean retaining the original fixed rate EIR, resulting in the computation and recognition of a gain or loss based on the change of rate discounted at the original fixed EIR. [IFRS 9.5.4.3]. Note that if the maturity of the renegotiated loan is at the same time extended compared to the original loan (for example from 10 years to 15 years), the penalty paid to compensate the lender for the movements in market rate over the residual maturity of the original 10-year loan should be amortised over this remaining period only and not over the extended maturity from years 11 to 15, consistently with the guidance on EIR and amortisation periods (see section 3.1.1 above).

In some instances, new legislation may be enacted that modifies the contractual cashflows of a financial asset or liability. If the change in the contractual cash flows does not result in derecognition, the modification is accounted for as follows:

- If the legislation is enforceable automatically, then the modification of the contractual cashflows is accounted for when the legislation is enacted. [IFRS 9.5.4.3].
Or
- If the change in law allows the customer a choice in whether or not they want to participate, then the cashflows under the new legislation are estimated, and any resulting changes are treated as a modification. [IFRS 9.5.4.3]. Over time the estimated cashflows are reassessed, and any revisions to the cashflow estimates are treated as a change in estimate as outlined in section 3.4.1 above.
[IFRS 9.B5.4.6].

Under both scenarios described above, the modification of the cashflows as a result of the new legislation is treated in line with IFRS 9.5.4.3. However, in the second scenario, as the legislation is not automatically enforced, the impact on the cashflows will be estimated based on an assessment of the timing and number of customers that will take up the changes, and this estimate is subsequently re-assessed to determine any revisions required.

3.8.2 Treatment of modification fees

Assuming that the modification does not result in the derecognition of the financial asset, IFRS 9 requires that changes in the contractual cash flows of the asset are recognised in profit or loss and any costs or fees incurred adjust the carrying amount of the modified financial asset and are amortised over the remaining term of the modified financial asset together with any pre-existing unamortised fees (see Chapter 48 for further discussions and examples). [IFRS 9.5.4.3]. Therefore, once the calculation of the modification gain or loss has been performed, the original EIR determined at initial recognition will be revised to reflect any new costs or fees incurred.

Illustration 3-15: Accounting treatment of modification fees

The terms of a loan are modified and the revised contractual cash flows discounted at the original EIR, determined at initial recognition, are CU5,000 (CU6,050 receivable in two years discounted at 10% per annum). If the bank incurs external costs related to the modification of CU50, e.g., for valuation of collateral and legal services, the original EIR of 10% will be revised to approximately 9%, i.e., the discount rate that discounts CU6,050 receivable in two years to a present value of CU5,050.

For modified financial assets, while the standard deals with 'costs and fees incurred', it is not as clear as to the appropriate treatment by the lender when modification fees are charged to the borrower. One view could be that they should be included in the modification gain or loss as they are part of the modified contractual cash flows and do not represent 'fees incurred'.

Alternatively, one might argue that the fees charged to the borrower would adjust the carrying amount of the loan. As a variation to the above Illustration, assume there are no external fees incurred by the lender, rather CU60 of fees are charged to the customer. The effect of this approach would be to revise the carrying amount of the loan to CU4,940 (CU5,000 - 60) and the EIR to 11%. This would be consistent with the principle in IFRS 9.B5.4.2, which explains that origination and commitment fees are an integral part of the EIR and, therefore, amortised over the term of the financial asset in accordance with the effective interest method. [IFRS 9.B5.4.2].

With respect to the accounting by a borrower of modification fees paid by a borrower, IFRS 9 requires that any transaction costs or fees incurred adjust the carrying amount of the liability and are amortised over the remaining term of the modified liability. [IFRS 9.B3.3.6]. This results in a revision of the original EIR, as explained above. This is in line with IFRS 9.BC4.253 that explains that the amortised cost of a financial liability should be adjusted in the same way that the gross carrying amount of a financial asset is adjusted when a modification does not result in the derecognition of the financial asset. [IFRS 9.BC4.253, IFRS 9.5.4.3].

Since costs and fees paid to the lender are amortised over the remaining term of the modified liability, while changes to future cash flows paid to the lender are recognised immediately in profit or loss, it is necessary to consider whether the substance of a payment is different from its form. This is discussed in more detail in Chapter 48.

3.8.3 Interbank Offered Rate (IBOR) reform

As a result of the reforms mandated by global regulators following the financial crisis, benchmark interbank offered rates (IBORs) have largely been replaced by new benchmark rates known as Risk Free Rates (RFRs).¹² In 2018, the IASB commenced a project to consider the accounting implications of the reform and divided its work into two phases:

- Phase 1: addressed issues affecting financial reporting in the period before replacement of an existing IBOR. And
- Phase 2: focused on issues that affect financial reporting when an existing interest rate benchmark is replaced with an RFR.

The IASB completed its project and published the amendments to several standards, including IAS 39 and IFRS 9, corresponding to Phase 1 and Phase 2 in September 2019 and August 2020 respectively. More information about how the amendments are applied in practice and their accounting implications is provided in *Supplement: IBOR Reform*.

3.8.4 Post implementation review

The IASB completed the post implementation review of the classification and measurement requirements of IFRS 9 in 2022. In December 2022, the IASB issued a report¹³ containing feedback from the classification and measurement PIR and noted the requirements are working as intended, however they noted that clarification was needed in certain areas to improve the understandability of the requirements. The feedback on the requirements for the modification of financial assets and financial liabilities was that there is diversity in practice in applying the requirements. Respondents recommended that additional application guidance be provided to improve consistency of application, including guidance on:

- What constitutes a modification
- When a modification leads to derecognition, including how to assess whether a modification is substantial, and when to use quantitative or qualitative factors (or both)
- What the difference between partial derecognition and a modification is, and what the subsequent accounting is for the remaining modified instrument
- Calculating and recognising a modification gain or loss (including where this should be recognised)
- The effect on the EIR of a modification (for example, when the interest changes from fixed to floating or *vice versa*)
- The accounting for unamortised transaction costs and any fees received as part of the modification
- And
- The meaning of 'fees and costs incurred' in IFRS 9.5.4.3

12 The transition for all GBP, EUR, CHF and JPY LIBOR settings and the one week and two-month USD LIBOR settings was 31 December 2021. The transition for overnight and 12-month USD LIBOR was 30 June 2023, and the remaining synthetic USD LIBOR settings (1-month, 3-month and 6-month) ceased on 30 September 2024.

13 [Project Report and Feedback Statement: Post-implementation Review, IFRS 9 Financial Instruments-Classification and Measurement](#), IASB, December 2022. Available on the IFRS Foundation's website.

Respondents also noted it would be helpful if the IASB provides further guidance on the requirements for the modification of financial assets and in particular:

- To what extent the reason for the modification (for example, forbearance versus on market-negotiations) affects whether a modification results in derecognition
- The relationship between modifications, the application of the EIR method and the expected credit loss requirements

The IASB acknowledged the potential intersection of the application of amortised cost accounting, modification accounting and expected credit losses, and therefore added the “Amortised Cost Measurement” project to its research pipeline in July 2022 and moved the project to a research work plan in September 2024. As discussed in section 3.1.3 above, the IASB has also completed its PIR of the impairment requirements in IFRS 9 and will aim to clarify, through targeted improvements, the requirements for modification, derecognition and write-off of financial instruments and the consequential effect on recognition of expected credit losses as part of its Amortised Cost Measurement project.¹⁴

In February 2025 the IASB determined the objectives, scope and timeline of the project.¹⁵ The scope is split into two themes, being i) changes in expected cash flows that affect the EIR (both at initial recognition and subsequent measurement), and ii) changes in expected cash flows that affect the carrying amount. The first theme is discussed in section 3.1.3 above. The second theme will explore what constitutes a ‘modification’, assess which modifications lead to derecognition and will compare partial derecognition versus modifications of financial instruments accounting, as well as explore the boundaries between modifications, derecognition and impairment. As part of the second theme, the project will consider accounting for modification gains or losses, unamortised transaction costs and fees received in modifications as well as accounting for ‘fees and costs incurred’ in terms of IFRS 9.5.4.3. In June 2025, the IASB decided to move the project to the standard-setting work plan.¹⁶ Deliberations on the first theme began in Q2 2025 and Q3 2025 and those on the second theme are planned to begin in Q4 2025 and Q1 2026.

4 Foreign currencies

4.1 Foreign currency instruments

The provisions of IAS 21 apply to transactions involving financial instruments in just the same way as they do for other transactions, although the manner in which certain hedges are accounted for can override its general requirements.

Consequently, the statement of financial position measurement of a foreign currency financial instrument is determined as follows:

- First, it is recorded and measured in the foreign currency in which it is denominated, whether it is carried at fair value, cost, or amortised cost.
- Second, that amount is retranslated to the entity's functional currency using the closing rate.

[IAS 21.23].

Profit and loss items associated with financial instruments, e.g., dividends receivable, interest payable or receivable and impairments, are recorded at the spot rate ruling when they arise (although average rates may be used when they represent an appropriate approximation to spot rates throughout the period).

The reporting of exchange differences in profit or loss or in other comprehensive income depends on whether the instrument is a monetary item (e.g., debt instruments) or a non-monetary item (e.g., an equity investment), and whether it is designated as part of a foreign currency cash flow hedge. (This excludes the translation of foreign entities which is addressed in section 4.2 below.)

Foreign exchange differences arising on retranslating monetary items, including debt instruments measured at fair value through other comprehensive income, are generally recognised in profit or loss. However, those exchange differences must be recognised in other comprehensive income for instruments designated as a hedging instrument in a cash flow hedge or in a hedge of a net investment in a foreign operation (except to the extent that there is hedge ineffectiveness). Exchange differences must also be recorded in other comprehensive income for a fair value hedge of an equity instrument for which an entity has elected to present changes in fair value in other comprehensive income (see section 2.5 above and Chapter 49). *[IFRS 9.B5.7.2, IFRS 9.B5.7.2A].*

Any changes in the carrying amount of a non-monetary item are recognised in profit or loss or in other comprehensive income in accordance with IFRS 9. For example, for an instrument that is measured at fair value through profit or loss, all subsequent fair value changes, including the effect of foreign exchange, are recognised in profit or loss. Similarly, for an investment in an equity instrument where an entity has made an irrevocable election to present in other comprehensive income subsequent changes in the fair value of the investment, the entire change in the carrying amount, including the effect of changes in foreign currency rates, is presented in other comprehensive income. *[IFRS 9.5.7.5, IFRS 9.B5.7.3, IFRS 9.IG E.3.4].*

In cases where some portion of the change in carrying amount is recognised in profit or loss and some in other comprehensive income, e.g., if the amortised cost of a foreign currency bond measured at fair value through other comprehensive income has increased in the foreign currency (resulting in a gain in profit or loss) but its fair value has decreased in the foreign currency (resulting in a loss recognised in other comprehensive income), those two components cannot be offset for the purposes of determining gains or losses that should be recognised in profit or loss or in other comprehensive income. *[IFRS 9.IG E.3.4].*

The Board developed the example below to illustrate the separation of the currency component for a financial asset that is measured at fair value through other comprehensive income in accordance with IFRS 9.4.1.2A. To simplify the example, the Board did not reflect the need to record expected credit losses. *[IFRS 9.IG E.3.2].* A more complex illustration, including expected credit losses is included in Chapter 47.

Illustration 4-1: Foreign currency debt security measured at fair value through other comprehensive income (separation of currency component)

On 31 December 20X1, Company A, whose functional currency is the euro, acquires a dollar bond for its fair value of \$1,000. The bond has five years to maturity and a \$1,250 principal, carries fixed interest of 4.7% paid annually ($\$1,250 \times 4.7\% = \59 per year), and has an effective interest rate of 10%.

A classifies the bond as subsequently measured at fair value through other comprehensive income in accordance with IFRS 9.4.1.2A, and thus recognises gains and losses in other comprehensive income. The exchange rate is initially \$1 to €1.50 and the carrying amount of the bond is €1,500 ($\$1,000 \times 1.50$).

		€	€
Dr	Bond	1,500	
	Cr Cash		1,500

On 31 December 20X2, the dollar has appreciated and the exchange rate is \$1 to €2.00. The fair value of the bond is \$1,060 and therefore its carrying amount is €2,120 ($\$1,060 \times 2.00$). Its amortised cost is \$1,041 (or €2,082 = $\$1,041 \times 2.00$) and the cumulative gain or loss to be included in other comprehensive income is the difference between its fair value and amortised cost, i.e., a gain of €38 ($\text{€}2,120 - \text{€}2,082$; or, alternatively, $[\$1,060 - \$1,041] \times 2.00$).

Interest received on the bond on 31 December 20X2 is \$59 (or €118 = $\$59 \times 2.00$). Interest revenue determined in accordance with the effective interest method is \$100 ($\$1,000 \times 10\%$) of which \$41 ($\$100 - \59) is the accretion of the initial discount.

It is assumed that the average exchange rate during the year is \$1 to €1.75 and that the use of an average exchange rate provides a reliable approximation of the spot rates applicable to the accrual of interest during the year. Therefore, reported interest revenue is €175 ($\$100 \times 1.75$) including accretion of the initial discount of €72 ($\$41 \times 1.75$).

The exchange difference recognised in profit or loss is €525, which comprises three elements: a €500 gain from the retranslation of the initial amortised cost ($\$1,000 \times [2.00 - 1.50]$); a €15 gain from the retranslation of interest revenue received ($\$59 \times [2.00 - 1.75]$) and a €10 gain on the retranslation of the interest revenue accreted ($\$41 \times [2.00 - 1.75]$).

		€	€
Dr	Bond	620	
Dr	Cash	118	
	Cr Interest revenue (P&L)		175
	Cr Exchange gain (P&L)		525
	Cr Fair value change in other comprehensive income (equity)		38

On 31 December 20X3, the dollar has appreciated further and the exchange rate is \$1 to €2.50. The fair value of the bond is \$1,070 and therefore its carrying amount is €2,675 ($\$1,070 \times 2.50$). Its amortised cost is \$1,086 (or €2,715 = $\$1,086 \times 2.50$) and the cumulative gain or loss to be included in other comprehensive income is the difference between its fair value and the amortised cost, i.e., a loss of €40 ($\text{€}2,675 - \text{€}2,715$; or, alternatively, $[\$1,070 - \$1,086] \times 2.50$). Therefore, there is a debit to other comprehensive income equal to the change in the difference during 20X2 of €78 ($\text{€}40 + \text{€}38$).

Interest received on the bond on 31 December 20X3 is \$59 (or €148 = $\$59 \times 2.50$). Interest revenue determined in accordance with the effective interest method is \$104 ($\$1,041 \times 10\%$), of which \$45 ($\$104 - \59) is the accretion of the initial discount.

Using the same assumptions as in the previous year, interest income is €234 ($\$104 \times 2.25$) including accretion of the initial discount of €101 ($\$45 \times 2.25$).

The exchange difference recognised in profit or loss is €547, which again comprises three elements: a €521 gain from the retranslation of the opening amortised cost ($\$1,041 \times [2.50 - 2.00]$); a €15 gain from the retranslation of interest income received ($\$59 \times [2.50 - 2.25]$) and an €11 gain on the retranslation of the interest income accreted ($\$45 \times [2.50 - 2.25]$).

4.2 Foreign entities

IFRS 9 did not amend the application of the net investment method of accounting for foreign entities set out in IAS 21 (see Chapter 16). Therefore, for the purpose of preparing its own accounts for inclusion in consolidated accounts, a foreign entity that is part of a group applies the principles in section 4.1 above by reference to its own functional currency. Consequently, the treatment of gains and losses on, say, trading assets held by a foreign entity should follow the treatment in the Illustration below, adapted from the Implementation Guidance of IFRS 9. [IFRS 9.IG E.3.3].

Illustration 4-2: Interaction of IAS 21 and IFRS 9: foreign currency debt investment

Company A is domiciled in the US and its functional currency and presentation currency is the US dollar. A has a UK domiciled subsidiary, B, whose functional currency is sterling. B is the owner of a debt instrument which is held for trading and is therefore carried at fair value through profit or loss in accordance with IFRS 9.

In B's financial statements for 20X1, the fair value and carrying amount of the debt instrument is £100. In A's consolidated financial statements, the asset is translated into US dollars at the spot exchange rate applicable at the end of the reporting period, say 2.0, and the carrying amount is US\$200 (£100 × 2.0).

At the end of 20X2, the fair value of the debt instrument has increased to £110. B reports the trading asset at £110 in its statement of financial position and recognises a fair value gain of £10 in profit or loss. During the year, the spot exchange rate has increased from 2.0 to 3.0 resulting in an increase in the fair value of the instrument from US\$200 to US\$330 (£110 × 3.0). Therefore, A reports the trading asset at US\$330 in its consolidated financial statements.

Since B is classified as a foreign entity, A translates B's statement of comprehensive income 'at the exchange rates at the dates of the transactions'. Since the fair value gain has accrued through the year, A uses the average rate of 2.5 (= [3.0 + 2.0] ÷ 2) as a practical approximation. Therefore, while the fair value of the trading asset has increased by US\$130 (US\$330 - US\$200), A recognises only US\$25 (£10 × 2.5) of this increase in profit or loss. The resulting exchange difference, i.e., the remaining increase in the fair value of the debt instrument of US\$105 (US\$130 - US\$25), is recognised in other comprehensive income until the disposal of the net investment in the foreign entity.

Another situation where foreign exchange differences on monetary items are recognised in other comprehensive income is when the long-term debt is considered to form part of the net investment in the foreign entity.

5 Future developments

In 2022 the IASB concluded its post implementation review of the classification and measurement requirements of IFRS 9 and added the “Amortised Cost Measurement” project to its project pipeline in July 2022. The IASB moved the project to a research work plan in September 2024 and in February 2025 determined the objectives, scope and timeline of the project.¹⁷ The scope is split into two themes, being i) changes in expected cash flows that affect the EIR (both at initial recognition and subsequent measurement), and ii) changes in expected cash flows that affect the carrying amount. Refer to section 3.1.3 and section 3.8.4 above for more information.

¹⁷ [IASB Staff Paper AP11](#): Project: *Amortised Cost Measurement*, Topic: *Project plan*, IASB meeting, February 2025. Available on the IFRS Foundation's website.

Appendix B - Index of Frequently asked questions

Question 2-1:	How should fees received (or paid) upfront to secure a loan commitment be accounted for in the Statement of Comprehensive Income?	3792
Question 2-2:	How should fees received (or paid) to secure a loan commitment be accounted for when management initially expects only a portion of the loan commitment to be utilised?	3793
Question 2-3:	How should fees received (or paid) to secure a loan commitment be accounted for when management does not expect any of the loan commitment to be utilised?	3793
Question 2-4:	How should fees received (or paid) to secure a loan commitment be accounted for when the loan commitment does not expire after being utilised?	3793
Question 3-1:	Does 'subsequent reporting period' refer only to annual periods or does it also extend to interim reporting periods?	3799
Question 3-2:	IAS 34.28 requires that the frequency of an entity's reporting shall not affect the measurement of its annual results. If interim reporting periods are 'reporting periods', are the IFRS 9 requirements to give effect to changes between gross and net interest calculation in the 'subsequent reporting period' inconsistent with the requirement in IAS 34.28, and in that case, which standard's guidance should be followed?	3799
Question 3-3:	Are entities allowed to perform the impairment assessments, with the resulting changes to the interest calculation, more frequently than their interim reporting periods, for example, monthly?	3799

Appendix C - Defined terms

Extract from IFRS standards - Definitions

amortised cost of a financial asset or financial liability	The amount at which the financial asset or financial liability is measured at initial recognition minus the principal repayments, plus or minus the cumulative amortisation using the effective interest method of any difference between that initial amount and the maturity amount and, for financial assets, adjusted for any loss allowance . [IFRS 9 Appendix A].
credit-impaired financial asset	<p>A financial asset is credit-impaired when one or more events that have a detrimental impact on the estimated future cash flows of that financial asset have occurred. Evidence that a financial asset is credit-impaired include observable data about the following events:</p> <ul style="list-style-type: none"> (a) significant financial difficulty of the issuer or the borrower; (b) a breach of contract, such as a default or past due event; (c) the lender(s) of the borrower, for economic or contractual reasons relating to the borrower's financial difficulty, having granted to the borrower a concession(s) that the lender(s) would not otherwise consider; (d) it is becoming probable that the borrower will enter bankruptcy or other financial reorganisation; (e) the disappearance of an active market for that financial asset because of financial difficulties; or (f) the purchase or origination of a financial asset at a deep discount that reflects the incurred credit losses. <p>It may not be possible to identify a single discrete event- instead, the combined effect of several events may have caused financial assets to become credit-impaired. [IFRS 9 Appendix A].</p>
credit risk	The risk that one party to a financial instrument will cause a financial loss for the other party by failing to discharge an obligation. [IFRS 7 Appendix A].
dividends	Distributions of profits to holders of equity instruments in proportion to their holdings of a particular class of capital. [IFRS 9 Appendix A].
effective interest method	The method that is used in the calculation of the amortised cost of a financial asset or a financial liability and in the allocation and recognition of the interest revenue or interest expense in profit or loss over the relevant period. [IFRS 9 Appendix A].
effective interest rate	The rate that exactly discounts estimated future cash payments or receipts through the expected life of the financial asset or financial liability to the gross carrying amount of a financial asset or to the amortised cost of a financial liability . When calculating the effective interest rate, an entity shall estimate the expected cash flows by considering all the contractual terms of the financial instrument (for example, prepayment, extension, call and similar options) but shall not consider the expected credit losses . The calculation includes all fees and points paid or received between parties to the contract that are an integral part of the effective interest rate (see paragraphs B5.4.1-B5.4.3), transaction costs , and all other premiums or discounts. There is a presumption that the cash flows and the expected life of a group of similar financial instruments can be estimated reliably. However, in those rare cases when it is not possible to reliably estimate the cash flows or the expected life of a financial instrument (or group of financial instruments), the entity shall use the contractual cash flows over the full contractual term of the financial instrument (or group of financial instruments). [IFRS 9 Appendix A].

gross carrying amount of a financial asset	The amortised cost of a financial asset , before adjusting for any loss allowance . <i>[IFRS 9 Appendix A]</i> .
reclassification date	The first day of the first reporting period following the change in business model that results in an entity reclassifying financial assets. <i>[IFRS 9 Appendix A]</i> .
purchased or originated credit-impaired financial asset	Purchased or originated financial asset(s) that are credit-impaired on initial recognition. <i>[IFRS 9 Appendix A]</i> .

Overview

This chapter addresses the IFRS 9 *Financial Instruments* expected credit loss accounting model and discusses some practical and implementation issues resulting from the impairment requirements.

Since IFRS 9 was issued in 2014, a number of interpretation and application issues have been identified, many of which have been the subject of discussion by the IFRS Transition Resource Group for Impairment of Financial Instruments established by the IASB and further guidance has been provided by the IASB in the form of webcasts and educational materials (see section 1.4 below) and by banking regulators (see sections 1.5 and 7.1 below).

The key differences between the IFRS and US GAAP guidance on this topic are addressed in section 1.3 below, although the standards are not converged and other similarities and differences between IFRS and US GAAP may exist that are not discussed in this chapter.

This chapter also briefly describes the credit risk disclosures in relation to the expected credit loss model as set out in IFRS 7 *Financial Instruments: Disclosures* (see section 15 below). A more detailed discussion of the disclosure requirements can be found in Chapter 50.

What you need to know

- The expected credit loss model applies to debt instruments held that are recorded at amortised cost or at fair value through other comprehensive income, such as loans, debt securities and trade receivables and, in addition, to lease receivables and most loan commitments and financial guarantee contracts.
- Under the general approach, all entities are required to recognise an allowance for either 12-month or lifetime expected credit losses, depending on whether there has been a significant increase in credit risk since initial recognition.
- The simplified approach, that is either required or available as an accounting policy choice for trade receivables, contract assets and lease receivables, does not require an entity to track the changes in credit risk, but instead requires the entity to recognise lifetime expected credit losses at each reporting date.
- For financial assets that are purchased or originated when they are already credit-impaired, entities are required to include the initial lifetime expected credit losses in a credit-adjusted effective interest rate instead of as an allowance, and to recognise subsequent changes in expected credit losses as an impairment gain or loss at each reporting date.
- The measurement of expected credit losses reflects a probability-weighted outcome, the time value of money and the best available forward-looking information.
- The need to incorporate forward-looking information means that application of IFRS 9 requires considerable judgement as to how changes in macroeconomic factors affect expected credit losses. The significant judgements required in making the expected credit loss calculation also means that it may be difficult to compare the reported results of different entities. However, entities are required to explain their inputs, assumptions and techniques used in estimating the expected credit loss requirements, which help provide transparency in respect of entities' credit risk and provisioning processes.
- The need to assess whether there has been a significant increase in credit risk in the expected credit loss model also requires judgement, specific data and processes.
- The expected credit loss model must also be applied to intercompany loans in the separate financial statements of group companies.

1 Introduction

In July 2014, the IASB issued the final version of IFRS 9, bringing together the classification and measurement, impairment and hedge accounting phases of the IASB's project to replace IAS 39 *Financial Instruments: Recognition and Measurement* and all previous versions of IFRS 9.

The IASB sought to address a key concern that arose as a result of the financial crisis in 2007 and 2008, that the incurred loss model in IAS 39 resulted in the delayed recognition of credit losses. As such, it introduced a forward-looking expected credit loss model. The expected credit loss requirements and application guidance in IFRS 9 are accompanied by 14 Illustrative Examples.

This section provides an overview of the impairment project, the IFRS 9 impairment requirements, key differences from the US GAAP as well as guidance provided by the IASB, the IFRS Transition Resource Group for Impairment of Financial Instruments and banking regulators.

1.1 Brief history and background of the impairment project

During the 2007/8 global financial crisis, the recognition of credit losses that were associated with loans and other financial instruments was identified as a weakness in existing accounting standards. This was primarily due to the fact that the previous impairment requirements under IAS 39 were based on an incurred loss model, i.e., credit losses were not recognised until a credit loss event had occurred. Since losses are rarely incurred evenly over the lives of loans, there was a mismatch in the timing of the recognition of the credit spread that is inherent in the interest accrued on loans over their lives and any impairment losses that were only recognised at a later date. A further identified weakness was the complexity of different entities using different approaches to calculate impairment.

In November 2009, the IASB issued an Exposure Draft - *Financial Instruments: Amortised Cost and Impairment* (the 2009 exposure draft) - that proposed an impairment model based on expected losses, rather than on incurred losses, for all financial assets recorded at amortised cost. In this approach, the initial expected credit losses were to be recognised over the life of a financial asset, by including them in the computation of the effective interest rate when the asset was first recognised. This would build an allowance for credit losses over the life of a financial asset and so match the recognition of credit losses with that of the credit spread implicit in the interest charged. Subsequent changes in credit loss expectations would be reflected in catch-up adjustments to profit or loss based on the original effective interest rate.

Comments received on the 2009 exposure draft and during the IASB's outreach activities indicated that constituents were generally supportive of a model that distinguished between the effect of initial estimates of expected credit losses and subsequent changes in those estimates. However, they were also concerned about the operational difficulties in implementing the model proposed.

To address these operational challenges, the IASB decided to decouple the measurement and allocation of initial expected credit losses from the determination of the effective interest rate (except for purchased or originated credit-impaired financial assets). Financial assets and their loss allowances would be measured separately, using an original effective interest rate that was not adjusted for initial expected credit losses. This approach would help address the operational challenges raised and allow entities to leverage their existing accounting and credit risk management systems and so reduce the extent of the necessary integration between these systems. [IFRS 9.BC5.92].

By decoupling expected credit losses from the effective interest rate, an entity must measure the present value of expected credit losses using the original effective interest rate. This presents a dilemma, because measuring expected credit losses using such a rate double-counts the expected credit losses that were priced into the financial asset at initial recognition. This is because the fair value of the loan at original recognition already reflects the expected credit losses, so to provide for the expected credit losses as an additional allowance would be to double count these losses. Hence, the IASB concluded that it was not appropriate to recognise lifetime expected credit losses on initial recognition. In order to address the operational challenges whilst trying to reduce the effect of double-counting, as well as to replicate (approximately) the outcome of the 2009 exposure draft, the IASB decided to pursue a dual-measurement model that would require an entity to recognise: [IFRS 9.BC5.93]

- A portion of the lifetime expected credit losses from initial recognition as a proxy for recognising the initial expected credit losses over the life of the financial asset
- The lifetime expected credit losses when credit risk had increased since initial recognition (i.e., when the recognition of only a portion of the lifetime expected credit losses would no longer be appropriate because the entity has suffered a significant economic loss)

Subsequently, the IASB and FASB spent a considerable amount of time and effort developing a converged impairment model, however, ultimately, full convergence was not achieved (see Section 1.3 below).

[IFRS 9.BC5.96]

In March 2013, the IASB published a new Exposure Draft - *Financial Instruments: Expected Credit Losses* (the 2013 ED), based on proposals that grew out of the joint project with the FASB. The 2013 ED proposed that entities recognise a loss allowance or provision at an amount equal to 12-month credit losses for those financial instruments that had not yet seen a significant increase in credit risk since initial recognition, and lifetime expected credit losses once there had been a significant increase in credit risk. This new model was designed to:

- Ensure a more timely recognition of expected credit losses than the existing incurred loss model
- Distinguish between financial instruments that have significantly deteriorated in credit quality and those that have not
- Better approximate the economic expected credit losses

This two-step model was designed to approximate the build-up of the allowance as proposed in the 2009 exposure draft, but involving less operational complexity. Figure 1-1 below illustrates the stepped profile of the new model, shown by the solid line, compared to the steady increase shown by the black dotted line proposed in the 2009 exposure draft (based on the original expected credit loss assumptions and assuming no subsequent revisions of this estimate). It shows that the two-step model first overstates the allowance (compared to the method set out in the 2009 exposure draft), then understates it as the credit quality deteriorates, and then overstates it once again as soon as the deterioration is significant.

Figure 1-1: Accounting for expected credit losses - 2009 exposure draft versus IFRS 9

The IASB finalised the impairment requirements and issued them in July 2014, as part of the final version of IFRS 9 effective for annual periods beginning on or after 1 January 2018.

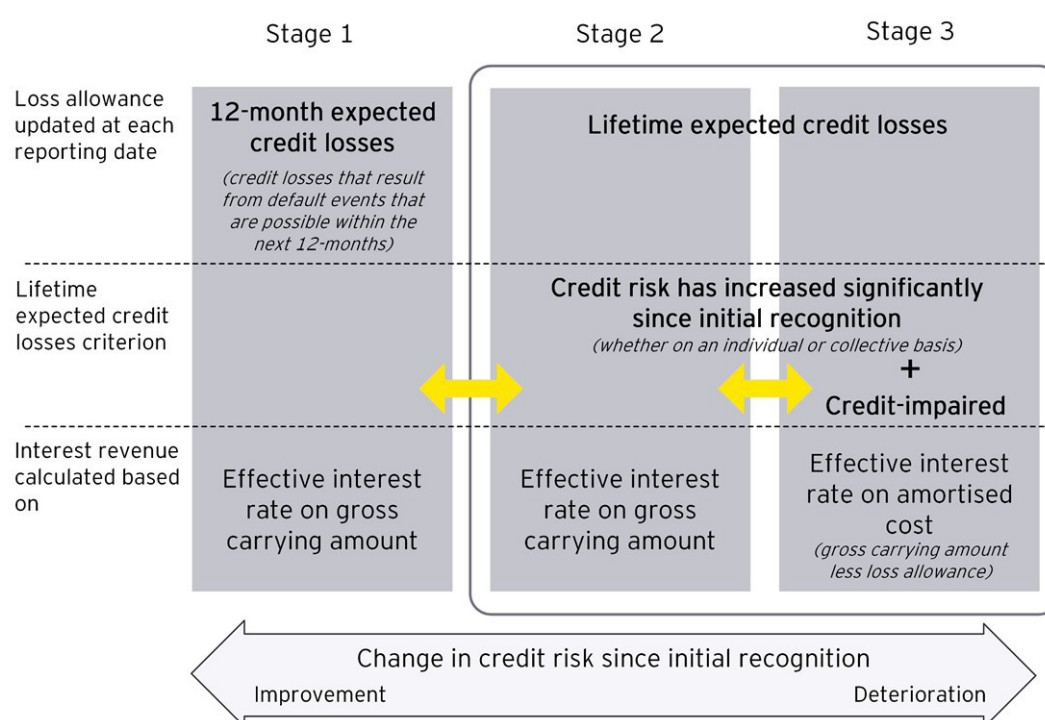

1.2 Overview of the IFRS 9 impairment requirements

The impairment requirements in IFRS 9 are based on an expected credit loss model and replaced the IAS 39 incurred loss model. The expected credit loss model applies to debt instruments (such as bank deposits, loans, debt securities and trade receivables) recorded at amortised cost or at fair value through other comprehensive income, plus lease receivables and contract assets. Loan commitments and financial guarantee contracts that are not measured at fair value through profit or loss are also included in the scope of the expected credit loss model.

Conceptually, an impairment model is a necessary complement to an accounting model for financial assets that is based on the concept of realisation, i.e., when cash flows are received and paid. For financial assets in the scope of the impairment model, the recognition of revenue follows the effective interest method, and gains and losses relating to changes in their fair value are generally only recognised in profit or loss when the financial asset is derecognised, and these gains or losses are realised. In order to avoid delaying the recognition of impairment losses, these accounting models are complemented by an impairment model that anticipates impairment losses by recognising them before they are realised. The impairment model of IFRS 9 does this on the basis of expected credit losses, which means impairment losses are anticipated earlier than under an incurred loss impairment model. In contrast, the accounting models for financial assets in IFRS 9 that are not based on the concept of realisation, i.e., those measured at fair value through profit or loss or at fair value through other comprehensive income without recycling (under the presentation choice for fair value changes of some investments in equity instruments, see Chapter 44 and Chapter 46) do not involve any separate impairment accounting. Those measurement categories implicitly include impairment losses in the fair value changes that are recognised immediately and without any later reclassification entries between other comprehensive income and profit or loss when they are realised.

The guiding principle of the expected credit loss model is to reflect the general pattern of deterioration, or improvement, in the credit quality of financial instruments. The expected credit loss approach has been commonly referred to as the three-bucket approach, although IFRS 9 does not use this term. Figure 1-2 below summarises the general approach in recognising either 12-month or lifetime expected credit losses.

Figure 1-2: General approach

The amount of expected credit losses recognised as a loss allowance or provision depends on the extent of credit deterioration since initial recognition. Under the general approach (see section 3.1 below), there are two measurement bases:

- 12-month expected credit losses (stage 1), which apply to all in scope assets as long as there is no significant deterioration in credit risk
- Lifetime expected credit losses (stages 2 and 3), which apply when a significant increase in credit risk has occurred on an individual or collective basis

When assessing significant increases in credit risk, there are a number of operational simplifications available, such as the low credit risk operational simplification (see section 6.4.1 below).

Stages 2 and 3 differ in how interest revenue is recognised. Under stage 2 (as under stage 1), there is a full decoupling between interest recognition and impairment, and interest revenue is calculated on the gross carrying amount. A financial asset is transferred to stage 3 when it is credit-impaired, defined as when one or more events that have a detrimental impact on the estimated future cash flows of that financial asset, have occurred. These criteria are set out in more detail in section 3.1 below. Under stage 3, interest revenue is calculated on the amortised cost (i.e., the gross carrying amount adjusted for the impairment allowance). [IFRS 9 Appendix A, IFRS 9.5.4.1].

As an exception to this model, there are separate rules if a financial asset is already credit-impaired on initial recognition (see section 3.3 below).

The following Illustration shows how the expected credit loss allowance changes when a loan moves from stage 1 to stage 3.

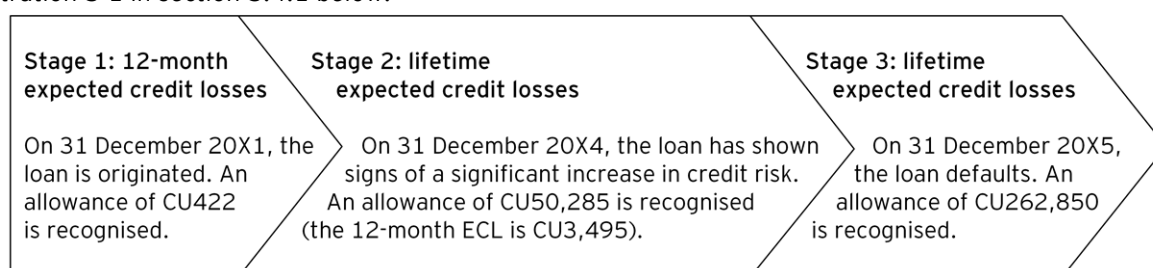

Illustration 1-1: Expected credit loss allowance in stages 1, 2 and 3 under the general approach

On 31 December 20X1, Bank A originates a 10 year loan with a gross carrying amount of CU1,000,000, with interest being due at the end of each year and the principal due on maturity. There are no transaction costs and the loan contracts include no options (for example, prepayment or call options), premiums or discounts, points paid, or other fees.

At origination, the loan is in stage 1 and a corresponding 12-month expected credit loss allowance is recognised in the year ending 31 December 20X1.

On 31 December 20X4, the loan has shown signs of significant deterioration in credit quality and Bank A moves the loan to stage 2. A corresponding lifetime expected credit loss allowance is recognised. In the following year, the loan defaults and is moved to stage 3.

The expected credit loss allowance in each stage is shown below and the detailed calculation is illustrated in Illustration 5-1 in section 5.4.1 below.

There are two alternatives to the general approach:

- The simplified approach, that is either required or available as a policy choice for trade receivables, contract assets and lease receivables (see section 3.2 below)
- The credit-adjusted effective interest rate approach, for purchased or originated credit-impaired financial assets (see section 3.3 below)

Expected credit losses are an estimate of credit losses over the next 12 months or the life of a financial instrument and, when measuring expected credit losses (see section 5 below), an entity needs to take into account:

- The probability-weighted outcome (see section 5.6 below), as expected credit losses are not simply either a best or a worst-case scenario, but, instead, reflect the possibility that a credit loss occurs and the possibility that no credit loss occurs. Following discussion at the IFRS Transition Resource Group for Impairment of Financial Instruments, this is understood to include a need to consider multiple economic scenarios (see section 5.6.1 below).
- The time value of money (see section 5.7 below).
- Reasonable and supportable information that is available without undue cost or effort at the reporting date about past events, current conditions and forecasts of future economic conditions (see section 5.9 below).

1.3 Key differences from the FASB's standard

On 16 June 2016, the FASB issued an Accounting Standard Update (ASU), *Financial Instruments - Credit Losses (Topic 326)*, that aims to address the same fundamental issue that the IASB's expected credit loss model (in IFRS 9) addresses, namely the delayed recognition of credit losses resulting from the incurred credit loss model. It is therefore also an expected credit loss model, but it is not the same as the model in IFRS 9.

The key differences between the IFRS and US GAAP guidance on this topic are highlighted below. The standards are not converged and not all the similarities and differences between IFRS and US GAAP on this topic are described.

FASB differences

The most significant differences between the FASB's and the IASB's expected credit loss models are, as follows:

- The FASB's expected credit loss model (known as the current expected credit loss or CECL model) does not apply to debt securities measured at fair value through other comprehensive income (i.e., available for sale debt securities under US GAAP). Rather, for available for sale debt securities, an allowance is recognised to reflect estimated credit losses and is adjusted over time to reflect both positive and adverse changes in expected cash flows.
- The FASB's expected credit losses are calculated based on the losses expected over the remaining contractual life of an asset considering the effect of prepayments. An allowance for lifetime expected credit losses is required when the loan is initially recognised instead of 12-month expected credit losses under IFRS 9. As a result, the FASB's model does not require an entity to assess whether there has been a significant deterioration in credit quality, in contrast to the assessment required by IFRS 9. This is similar to the IFRS 9 simplified approach (see section 3.2 below).
- The FASB's standard does not require, nor does it prohibit, an entity to use probability-weighted outcomes. However, entities are required to incorporate the risk of loss, even if such a risk is remote, into their estimate. It is expected that an allowance of zero will only be appropriate in very limited circumstances.
- For acquired financial assets (or acquired groups of financial assets with shared risk characteristics) that, as of the date of acquisition, have experienced a more-than-insignificant deterioration in credit quality since origination, i.e., financial assets purchased with credit deterioration, as determined by an acquirer's assessment and that are measured at amortised cost, the FASB's model requires an entity to determine the initial amortised cost of the assets by adding the allowance for credit losses at the date of acquisition (the entity's initial estimate of expected credit losses) to the purchase price. The subsequent measurement of expected credit losses for financial assets purchased with credit deterioration is the same as originated assets or non-financial assets purchased with credit deterioration acquired assets. See section 3.3 below for the accounting treatment of purchased or originated credit-impaired assets under IFRS 9.
- Under IFRS 9, there is an exception for revolving credit facilities (e.g., commitments connected with overdrafts and credit cards), that does not restrict the measurement of expected credit losses to losses expected in the period over which the facility is contractually committed (see section 12 below for the IFRS 9 treatment). Under the FASB's model, no impairment allowance is required on commitments that are unconditionally cancellable or legally revocable without any conditions.

1.4 The IFRS Transition Resource Group for Impairment of Financial Instruments, IASB webcasts and educational materials

In 2014, the IASB set up an IFRS Transition Resource Group for Impairment of Financial Instruments that aimed to:

- Provide a public discussion forum to support stakeholders on implementation issues arising from the new impairment requirements that could create diversity in practice.
- Inform the IASB about the implementation issues and to help the IASB determine what action, if any, was needed to address them.¹

However, the IFRS Transition Resource Group for Impairment of Financial Instruments did not issue any guidance.

Members of the IFRS Transition Resource Group for Impairment of Financial Instruments included financial statement preparers and auditors from various geographical locations with expertise, skills or practical knowledge on credit risk management and accounting for impairment. Board members and observers from the Basel Committee on Banking Supervision and the International Organisation of Securities Commissions also attended the meetings.

¹ [IASB Website Announcement](#), IASB to establish transition resource group for impairment of financial instruments, 23 June 2014. Available on the IFRS Foundation's website.

The IFRS Transition Resource Group for Impairment of Financial Instruments agenda papers were prepared by the IASB staff and were made public before the meetings. The staff also provided IFRS Transition Resource Group for Impairment of Financial Instruments meeting summaries, which are not authoritative. Both the staff papers and the meeting summaries represent educational reading on the issues submitted. Following its inaugural meeting in December 2014 to discuss its operating procedures, the IFRS Transition Resource Group for Impairment of Financial Instruments met three times, on 22 April 2015, on 16 September 2015, and on 11 December 2015.

On 22 April 2015, the IFRS Transition Resource Group for Impairment of Financial Instruments discussed eight implementation issues raised by stakeholders. These included:²

- When applying the impairment requirements at the reporting date, whether and how to incorporate events and forecasts that occur after economic forecasts have been made, but before the reporting date, and between the reporting period end and the date of signing the financial statements (see section 5.9.4 below).
- Whether the impairment requirements in IFRS 9 must also be applied to other commitments to extend credit, in particular, a commitment (on inception of a finance lease) to commence a finance lease at a date in the future and a commitment by a retailer through the issue of a store account to provide a customer with credit when the customer buys goods or services from the retailer in the future (see section 11.1 below).
- Whether there is a requirement to measure expected credit losses at dates other than the reporting date, namely the date of derecognition and the date of initial recognition (see section 7.3.1 below).
- Whether an entity should consider the ability to recover cash flows through an integral financial guarantee contract when assessing whether there has been a significant increase in the credit risk of the guaranteed debt instrument since initial recognition (see section 6.1.1 below).
- The maximum period to consider when measuring expected credit losses on a portfolio of mortgage loans that have a stated maturity of 6 months, but contain a contractual feature whereby the term is automatically extended every 6 months subject to the lender's non-objection (see section 5.5 below).
- The maximum period to consider when measuring expected credit losses for revolving credit facilities and the determination of the date of initial recognition of the revolving credit facilities for the purposes of assessing them for significant increases in credit risk (see sections 5.3, 12.2.2, 12.2.4 and 12.5 below).
- Whether the measurement of expected credit losses for financial guarantee contracts issued should consider future premium receipts due from the holder and, if so, how (see section 11.3 below).
- The measurement of expected credit losses in respect of a modified financial asset, the calculation of the modification gain or loss and subsequent requirement to measure expected credit losses on the modified financial asset as well as the appropriate presentation and disclosure (see section 8.2 below).

² IASB Transition Resource Group for Impairment of Financial Instruments, [Meeting Summary](#), 22 April 2015. Available on the IFRS Foundation's website.

On 16 September 2015, the IFRS Transition Resource Group for Impairment of Financial Instruments held its third meeting to discuss six implementation issues raised by stakeholders. These included:³

- How to identify a significant increase in credit risk for a portfolio of retail loans when identical pricing and contractual terms are applied to customers across broad credit quality bands (see section 6.4.5 below).
- The possibility of using behavioural indicators of credit risk for the purpose of the assessment of significant increases in credit risk since initial recognition (see section 6.2.5 below).
- When assessing significant increases in credit risk, whether an entity would be required to perform an annual review to determine whether circumstances still support the use of the 12-month risk of a default occurring as an approximation of changes in the lifetime risk of a default occurring (see section 6.4.3 below).
- When measuring expected credit losses for revolving credit facilities, how an entity should estimate future drawdowns on undrawn lines of credit when an entity has a history of allowing customers to exceed their contractually set credit limits on overdrafts and other revolving credit facilities (see section 12.3 below).
- At what level should forward-looking information be incorporated - at the level of the entity or on a portfolio-by-portfolio basis (see section 5.9.5 below).
- How to determine what is reasonable and supportable forward-looking information and how to treat shock events with material, but uncertain, economic consequences (see section 5.9.5 below).

On 11 December 2015, the IFRS Transition Resource Group for Impairment of Financial Instruments held its fourth meeting to discuss eleven implementation issues raised by stakeholders. These included:⁴

- What was meant by the 'current effective interest rate' when an entity recognises interest revenue in each period based on the actual floating-rate applicable to that period (see section 5.7 below).
- What was meant by 'part of the contractual terms', specifically whether a credit enhancement must be an explicit term of the related asset's contract in order for it to be taken into account in the measurement of expected credit losses, or whether other credit enhancements that are not recognised separately can also be taken into account (see section 5.8.1.A below).
- Whether cash flows that are expected to be recovered from the sale on default of a loan could be included in the measurement of expected credit losses (see section 5.8.2 below).
- Application of the revolving credit facilities exception set out in IFRS 9.5.5.20 to multi-purpose facilities (see sections 12.1 and 12.4 below).
- How future drawdowns should be estimated for charge cards when measuring expected credit losses if there is no specified credit limit in the contract (see section 12.1 below).
- How an entity should determine the starting-point and the ending-point of the maximum period to consider when measuring expected credit losses for revolving credit facilities (see section 12.2.2 below).
- When measuring expected credit losses, whether an entity can use a single forward-looking economic scenario or whether an entity needs to incorporate multiple forward-looking scenarios, and if so how (see sections 5.6.1, 5.6.2 and 5.9.5 below).
- When assessing significant increases in credit risk, whether an entity can use a single forward-looking economic scenario or whether the entity needs to incorporate multiple forward-looking scenarios, and if so how (see section 6.7 below).
- Whether there is a requirement to assess significant increases in credit risk for financial assets with a maturity of 12 months or less (see section 6 below).
- How to measure the gross carrying amount and loss allowance for credit-impaired financial assets that are not purchased or originated credit-impaired and that are measured at amortised cost (see section 14.1.2 below).
- Whether an entity is required to present the loss allowance for financial assets measured at amortised cost (or trade receivables, contract assets or lease receivables) separately in the statement of financial position (see section 14.1 below).

3 IASB Transition Resource Group for Impairment of Financial Instruments, [Meeting Summary](#), 16 September 2015. Available on the IFRS Foundation's website.

4 IASB Transition Resource Group for Impairment of Financial Instruments, [Meeting Summary](#), 11 December 2015. Available on the IFRS Foundation's website.

The IFRS IC discussed two issues in relation to the IFRS 9 expected credit loss model in November 2018:

- Whether the cash flows expected from a financial guarantee contract or any other credit enhancement can be included in the measurement of expected credit loss if the credit enhancement is required to be recognised separately applying IFRS accounting standards (see sections 5.8.1.A and 7.7.2 below).
- How an entity should present amounts recognised in the statement of profit or loss when a credit-impaired financial asset is subsequently cured, i.e., paid in full or no longer credit-impaired (see section 14.1.2 below).

In addition, as part of its activities to support implementation, the IASB has published three educational webcasts since IFRS 9 was published.⁵

- The first, on forward-looking information and multiple scenarios was released on 25 July 2016. It discussed when multiple scenarios need to be considered and the concept of non-linearity, consistency of scenarios, probability-weighted assessment of significant increase in credit risk, and approaches to incorporating forward-looking scenarios (see sections 5.6.1, 6.5.2, 6.5.3 and 6.7 below).
- The second, on the expected life of revolving facilities was released on 16 May 2017. It focused on how credit risk management actions would affect the expected life of revolving facilities for the purpose of measuring expected credit losses (see sections 12.2.3 and 12.5 below).
- The third, on curing of a credit-impaired financial asset was released on 22 July 2019. It summarised the IFRS ICs discussion and explained the conclusion it reached on how a company should present amounts in its statement of profit or loss if a credit-impaired financial asset is subsequently paid in full or no longer credit-impaired (cured) (see section 14.1.2 below).

In light of the coronavirus pandemic, on 27 March 2020, the IASB published *IFRS 9 and covid-19 - Accounting for expected credit losses applying IFRS 9 Financial Instruments in the light of current uncertainty resulting from the covid-19 pandemic*, to clarify application of the IFRS 9 expected credit loss requirements (see sections 5.6.3, 5.9.5, 6.2.3 and 7.8.2 below).

1.5 Other guidance on expected credit losses

In November 2015, the Enhanced Disclosure Task Force published its report, *Impact of Expected Credit Loss Approaches on Bank Risk Disclosures*, in which it recommended disclosures for banks to provide with the implementation of the expected credit loss requirements of IFRS 9 and US GAAP (see section 15 below).

In December 2015, the Basel Committee on Banking Supervision issued its *Guidance on accounting for expected credit losses*, aimed primarily at internationally active banks, which sets out supervisory expectations regarding sound credit risk practices associated with implementing and applying an expected credit loss accounting framework (see section 7.1 below).

On 17 June 2016, the Global Public Policy Committee of representatives of the six largest accounting networks (the GPPC) published *The implementation of IFRS 9 impairment by banks - Considerations for those charged with governance of systemically important banks* (the GPPC guidance) to promote a high standard in the implementation of accounting for expected credit losses. It aims to help those charged with governance to evaluate management's progress during the implementation and transition phase. A year later, on 28 July 2017, the GPPC issued a paper titled *The Auditor's Response to the Risks of Material Misstatement Posed by Estimates of Expected Credit Losses under IFRS 9* to assist audit committees to oversee the audit of expected credit losses (see section 7.2 below).

The European Central Bank issued a letter on 1 April 2020, *IFRS 9 in the context of the coronavirus (covid-19) pandemic*, that emphasised the importance of identifying and reporting asset quality deterioration. Subsequently, on 4 December 2020, the European Central Bank issued a letter to the CEOs of banks *Identification and measurement of credit risk in the context of the coronavirus (covid-19) pandemic* to provide banks with additional guidance on credit risk identification and measurement in the context of the coronavirus pandemic (see section 7.8.2 below).

⁵ IFRS 9 Financial Instruments: [Educational webcasts and webinars](#), IASB, available on the IFRS Foundation's website.

The Task Force on Disclosures about Expected Credit Losses (DECL) sponsored by UK regulators have published their third report *Recommendations on a comprehensive set of IFRS 9 Expected Credit Loss disclosures* in September 2022, which includes updates to the second report along with illustrative best practice examples to further aid the quality and comparability of disclosures between large UK banks.⁶ In addition, the European Securities and Market Authority published a report *On the application of the IFRS 7 and IFRS 9 requirements regarding banks' expected credit losses (ECL)* in December 2021 and has identified room for improvement in the level of compliance, comparability and transparency in the application of the relevant IFRS requirements.⁷ We expect regulator focus to continue in this Area (see Chapter 50).

1.6 Post Implementation Review

The IASB have completed their post-implementation review of IFRS 9 Financial Instruments Impairment. The objective of a post-implementation review is to assess whether the effects of applying the new requirements on users of financial statements, preparers, auditors and regulators are those the IASB intended when it developed the requirements. A post-implementation review does not automatically lead to standard-setting nor the resolution of every application question, however, the review can identify improvements to the relevant standard. On 4 July 2024 the IASB published *Post-Implementation Review of IFRS 9 Financial Instruments-Impairment Project and Feedback Statement*.⁸

Following the review the IASB concluded that the impairment requirements in IFRS 9 are working as intended and provide useful information to users of financial instruments. Specifically, they believe that the requirements:

- have led to more timely recognition of credit losses;
 - provide useful information to investors about expected credit losses, although targeted improvements to credit risk disclosures were suggested;
- And
- can generally be applied consistently, with some areas requiring further clarification and guidance.

The IASB are now exploring whether the requirements for modification, derecognition and write-off of financial instruments, and the consequential effects on recognition of expected credit losses, can be clarified as part of its project on Amortised Cost Measurement (see Chapter 46). Furthermore, the IASB has added a new project to its pipeline to investigate targeted improvements to the credit risk disclosure requirements in IFRS 7 *Financial Instruments: Disclosures*. It should be noted that now the IASB has concluded its PIR of impairment, any other previously identified areas where alternative treatments and accounting policy choices applied will remain, since no further guidance will be issued by the IASB with respect to the standard.

6 [Taskforce on Disclosures about Expected Credit Losses \(DECL\) updated guidance](#). Available on the Financial Reporting Council UK website.

7 ESMA publishes Report on Expected Credit Loss disclosures of banks. Available on the European Securities and Market Authority website.

8 [Project Summary and Feedback Statement](#). *Post-implementation Review of IFRS 9 Financial Instruments-Impairment*. Available on the IFRS Foundation's website.

2 Scope

IFRS 9 requires an entity to recognise a loss allowance for expected credit losses on: [IFRS 9.5.5.1]

- Financial assets that are debt instruments such as loans, debt securities, bank balances and deposits and trade receivables (see section 10 below) that are measured at amortised cost. [IFRS 9.4.1.2].
- Financial assets that are debt instruments measured at fair value through other comprehensive income (see section 9 below). [IFRS 9.4.1.2A].
- Finance lease receivables (i.e., net investments in finance leases) and operating lease receivables under IFRS 16 *Leases* (see section 10.2 below and Chapter 24).
- Contract assets under IFRS 15 *Revenue from Contracts with Customers* (see section 10.1 below and Chapter 28). IFRS 15 defines a contract asset as “an entity’s right to consideration in exchange for goods or services that the entity has transferred to a customer when that right is conditional on something other than the passage of time (for example, the entity’s future performance)”. [IFRS 15 Appendix A, IFRS 9 Appendix A].
- Loan commitments that are not measured at fair value through profit or loss under IFRS 9 (see sections 11 and 12 below). The scope therefore excludes loan commitments designated as financial liabilities at fair value through profit or loss, loan commitments that can be settled net in cash or by delivering or issuing another financial instrument and commitments to provide a loan at a below-market interest rate. [IFRS 9.2.1(g), IFRS 9.2.3, IFRS 9.4.2.1(a), IFRS 9.4.2.1(d)].
- Financial guarantee contracts that are not measured at fair value through profit or loss under IFRS 9 (see section 11 below).

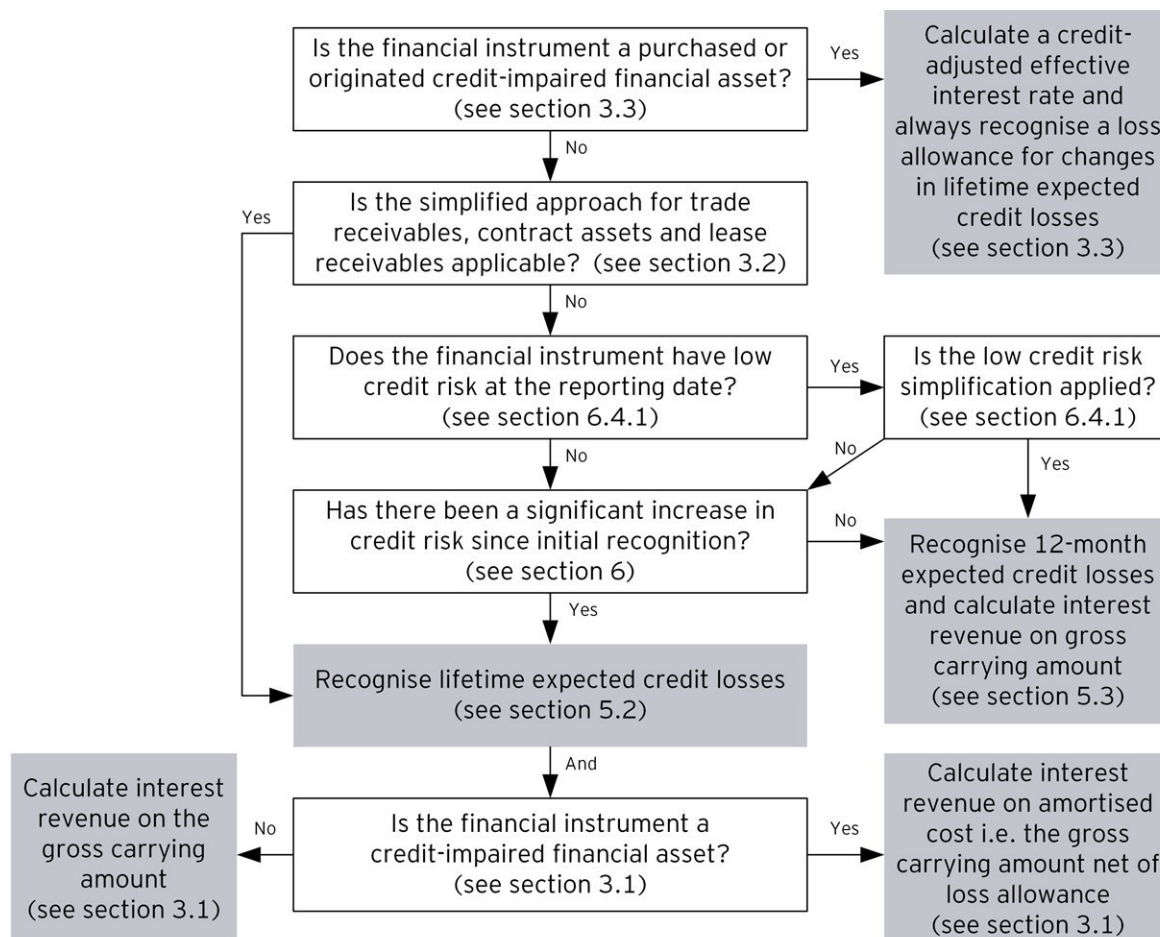

3 Approaches

In applying the IFRS 9 impairment requirements, an entity needs to follow one of the approaches below, subject to the conditions set out in each section:

- The general approach (see section 3.1 below)
- The simplified approach (see section 3.2 below)
- The purchased or originated credit-impaired approach (see section 3.3 below)

Figure 3-1 below, based on a diagram from IFRS 9, summarises the process steps in recognising and measuring expected credit losses.

Figure 3-1: Application of the impairment requirements at a reporting date

3.1 General approach

Under the general approach, at each reporting date, an entity recognises a loss allowance based on either 12-month expected credit losses or lifetime expected credit losses, depending on whether there has been a significant increase in credit risk on the financial instrument since initial recognition. [IFRS 9.5.5.3, IFRS 9.5.5.5]. The changes in the loss allowance balance are recognised in profit or loss as an impairment gain or loss. [IFRS 9.5.5.8, IFRS 9 Appendix A].

Essentially, an entity must make the following assessment at each reporting date:

- For credit exposures where there have not been significant increases in credit risk since initial recognition, an entity is required to provide for 12-month expected credit losses, i.e., the portion of lifetime expected credit losses that represent the expected credit losses that result from default events that are possible within the 12 months after the reporting date (stage 1 in Figure 1-2 in section 1.2 above). [IFRS 9.5.5.5, IFRS 9 Appendix A].
- For credit exposures where there have been significant increases in credit risk since initial recognition on an individual or collective basis, a loss allowance is required for lifetime expected credit losses, i.e., expected credit losses that result from all possible default events over the expected life of a financial instrument (stages 2 and 3 in Figure 1-2 in section 1.2 above). [IFRS 9.5.5.3, IFRS 9.5.5.4, IFRS 9 Appendix A].

- In subsequent reporting periods, if the credit quality of the financial instrument improves such that there is no longer a significant increase in credit risk since initial recognition, then the entity reverts to recognising a loss allowance based on 12-month expected credit losses (i.e., the approach is symmetrical and the financial instrument is moved from stage 2 or stage 3 into stage 1 in Figure 1-2 in section 1.2 above). [IFRS 9.5.5.7].

In certain circumstances, it is not practical to determine for every individual financial instrument whether there has been a significant increase in credit risk, because they may be individually immaterial and many in number and/or because there is no evidence available to do so. Consequently, it may be necessary to measure expected credit losses on a collective basis, to approximate the result of using comprehensive credit risk information that incorporates forward-looking information at an individual instrument level (see section 6.5 below). [IFRS 9.B5.5.1, IFRS 9.BC5.141].

IFRS 9 includes practical expedients, in particular the use of a simplified approach (see section 3.2 below) and a provision matrix (see section 10.1 below), to help measure the loss allowance for trade receivables.

To help enable an entity's assessment of significant increases in credit risk, IFRS 9 also provides the following operational simplifications:

- A low credit risk threshold equivalent to investment grade (see section 6.4.1 below), where no assessment of significant increases in credit risk is required.
- The ability to rely on past due information if reasonable and supportable forward-looking information is not available without undue cost or effort (see section 6.4.2 below). This is subject to the rebuttable presumption that there has been a significant increase in credit risk if a loan is more than 30 days past due (see section 6.2.2 below).
- Use of a change in the 12-month risk of a default as an approximation for change in lifetime risk (see section 6.4.3 below).

The IFRS 9 Illustrative Examples also provide the following suggestions on how to implement the assessment of significant increases in credit risk:

- Assessment at the counterparty level (see section 6.4.4 below)
- A set transfer threshold by determining maximum initial credit risk for a portfolio (see section 6.4.5 below)

In stages 1 and 2, there is a complete decoupling between interest recognition and impairment. Therefore, interest revenue is calculated on the gross carrying amount (without deducting the loss allowance). If a financial asset subsequently becomes credit-impaired (stage 3 in Figure 1-2 in section 1.2 above), an entity is required to calculate the interest revenue by applying the effective interest rate, from the start of the subsequent reporting period, to the amortised cost of the financial asset (i.e., the gross carrying amount net of loss allowance) rather than the gross carrying amount. [IFRS 9.5.4.1, IFRS 9 Appendix A].

A financial asset is credit-impaired when one or more events that have a detrimental impact on the estimated future cash flows of that financial asset have occurred. Evidence that a financial asset is impaired includes observable data about such events. IFRS 9 provides a list of events for an individual asset assessment: [IFRS 9 Appendix A]

- Significant financial difficulty of the issuer or the borrower
- A breach of contract, such as a default or past due event
- The lender(s) of the borrower, for economic or contractual reasons relating to the borrower's financial difficulty, having granted to the borrower a concession(s) that the lender(s) would not otherwise consider
- It is becoming probable that the borrower will enter bankruptcy or other financial reorganisation
- The disappearance of an active market for that financial asset because of financial difficulties
- The purchase or origination of a financial asset at a deep discount that reflects the incurred credit losses

It may not be possible for an entity to identify a single discrete event. Instead, the combined effect of several events may have caused the financial asset to become credit-impaired. [IFRS 9 Appendix A].

There has also been some debate as to whether financial assets that are considered to be in default (e.g., because payments are more than 90 days past due) but that are fully collateralised (so that there is no expected credit loss) would qualify as credit-impaired and therefore have to be transferred to stage 3. Although the definition of credit-impaired refers to 'a detrimental impact on the estimated future cash flows', it is not clear whether this is read to include any recoveries from the realisation of collateral and IFRS 9 has no explicit requirements to consider collateral when assessing credit-impaired financial assets.

How we see it

There are some strong arguments in favour of aligning the criteria for transferring an asset to stage 3 with those for assessing whether it is in default, even if the asset is fully collateralised. First, IFRS 9 bases significant deterioration on risk of a default occurring and it would therefore seem inconsistent (and potentially confusing for users) if the value of collateral is considered for stage 3 allocation. Also, if collateral value were to influence the stage 3 allocation, this could result in some instability between stage 2 and stage 3, as exposures would potentially go back and forth depending on the collateral value.

Aligning stage 3 with the default status affects the scope of instruments to which the purchased or originated credit-impaired approach must be applied. However, for any exposure which is fully collateralised and where the expected loss is zero, classification as a purchased or originated credit-impaired financial asset, or classification between stage 1, 2 or 3 does not affect the accounting. If the expected loss is zero, it will not affect the effective interest rate calculation.

Also, IFRS 7 requires a quantitative disclosure about the collateral held as security and other credit enhancements for financial assets that are credit-impaired at the reporting date (e.g., quantification of the extent to which collateral and other credit enhancements mitigate credit risk). [IFRS 7.35K(c)].

In subsequent reporting periods, if the credit quality of the financial asset improves so that the financial asset is no longer credit-impaired and the improvement can be related objectively to the occurrence of an event (such as an improvement in the borrower's credit rating), then the entity once again calculates the interest revenue by applying the effective interest rate to the gross carrying amount of the financial asset (i.e., the approach is symmetrical and the financial instrument is moved from stage 3 and into stage 1 or stage 2 in Figure 1-2 in section 1.2 above). [IFRS 9.5.4.2].

When the entity has no reasonable expectations of recovering a financial asset, in its entirety or a portion thereof, then the gross carrying amount of the financial asset is directly reduced. A write-off constitutes a derecognition event (see section 14.1.1 below). [IFRS 9.5.4.4].

3.2 Simplified approach

The simplified approach does not require an entity to track the changes in credit risk, but instead requires the entity to recognise a loss allowance based on lifetime expected credit losses at each reporting date. [IFRS 9.5.5.15].

An entity is required to apply the simplified approach for trade receivables or contract assets that result from transactions within the scope of IFRS 15 and that do not contain a significant financing component, or when the entity applies the practical expedient for contracts that have a maturity of one year or less, in accordance with IFRS 15 (see Chapter 28). [IFRS 9.5.5.15(a)(i)]. Paragraphs 60-65 of IFRS 15 provide the requirements for determining the existence of a significant financing component in the contract, including the use of the practical expedient for contracts that are one year or less.

A contract asset is defined as an entity's right to consideration in exchange for goods or services that the entity has transferred to a customer when that right is conditioned on something other than the passage of time (for example, the entity's future performance). [IFRS 15 Appendix A]. IFRS 15 describes contracts with a significant financing component as those for which the agreed timing of payment provides the customer or the entity with a significant benefit of financing on the transfer of goods or services to the customer. Hence, in determining the transaction price, an entity is required to adjust the promised amount of consideration for the effects of the time value of money. [IFRS 15.60]. However, if the entity expects, at contract inception, that the period between when the entity transfers a promised good or service to a customer, and when the customer pays for that good or service will be one year or less, as a practical expedient, an entity need not adjust the promised amount of consideration for the effects of a significant financing component. [IFRS 15.63].

How we see it

Application of the simplified approach to trade receivables and contract assets that do not contain a significant financing component intuitively makes sense. In particular, for trade receivables and contract assets that are due in 12 months or less, the 12-month expected credit losses are the same as the lifetime expected credit losses.

However, an entity has a policy choice to apply either the simplified approach or the general approach for the following: [IFRS 9.5.5.16]

- All trade receivables or contract assets that result from transactions within the scope of IFRS 15, and that contain a significant financing component in accordance with IFRS 15. The policy choice may be applied separately to trade receivables and contract assets (see section 10.1 below and Chapter 28). [IFRS 9.5.5.15(a)(ii)].
- All lease receivables that result from transactions that are within the scope of IFRS 16. The policy choice may be applied separately to finance and operating lease receivables (see section 10.2 below and Chapter 24). [IFRS 9.5.5.15(b)].

The IASB noted that offering this policy choice would reduce comparability. However, the IASB believes it would alleviate some of the practical concerns of tracking changes in credit risk for entities that do not have sophisticated credit risk management systems. [IFRS 9.BC5.225].

In practice, trade receivables may be sold to a factoring bank. In those instances, where all risks and rewards are transferred to the bank, the trade receivables are derecognised by the transferring entity and recognised by the factoring bank which obtains the right to receive the payments made by the debtor for the invoiced amount. In such a case, we believe that the 'factored' trade receivables are outside the scope of the simplified approach for the purpose of the factoring bank when applying the IFRS 9 expected credit loss model. This is because the simplified approach is limited to trade receivables that result from transactions within the scope of IFRS 15, i.e., based on a contract to obtain goods or services. This is not the case for the factoring bank since it has acquired the trade receivables through a factoring agreement. Moreover, the simplified approach was introduced to assist entities with less sophisticated credit risk management systems. [IFRS 9.BC5.104]. Factoring banks are likely to have more sophisticated credit risk management systems in place.

How we see it

Trade receivables that are sold to a factoring bank and derecognised are outside the scope of the simplified approach for the factoring bank when applying the IFRS 9 expected credit loss model.

3.3 Purchased or originated credit-impaired financial assets

On initial recognition of a financial asset, an entity is required to determine whether the asset is credit-impaired. The criteria are set out in section 3.1 above. [IFRS 9.5.5.3, IFRS 9.5.5.5, IFRS 9.5.5.13].

A financial asset may be purchased credit-impaired because the credit risk is very high and it has already met the criteria. Such an asset is likely to be acquired at a deep discount. However, this does not mean that an entity is required to apply the credit-adjusted effective interest rate to a financial asset solely because the financial asset has a high credit risk at initial recognition, if it has not yet met the criteria. [IFRS 9.B5.4.7]. Moreover, although one of the indicators that a financial asset is credit-impaired is that the asset is purchased at a deep discount, the purchased financial asset may be determined to be credit-impaired even if it is not purchased at a deep discount if the other indicators (see section 3.1 above) that the financial asset is credit-impaired are present. For instance, it is possible that a secured loan could be purchased credit-impaired, because one of the criteria is met, but not acquired at a deep discount due to the value of the collateral. It may be also possible that an entity originates a credit-impaired financial asset, for example, following a substantial modification of a distressed financial asset that resulted in the derecognition of the original financial asset (see section 8 below). [IFRS 9.B5.5.26].

Again, this does not mean that the asset is considered credit-impaired just because it is high risk. Consider an example of a bank originating a loan of CU100,000 with interest of 30% per annum charged over the term of the loan, payable in monthly amortising instalments. The bank's customer has a high credit risk on origination and the bank expects a large portion of this type of customer to pay late or fail to pay some or all of their instalment payments. Although the loan is of high credit risk (which is supported by the high interest rate), none of the loss events listed above have occurred and the loan was not the result of a substantial modification and derecognition of a distressed debt, hence, the bank assesses the loan not to be credit-impaired on origination.

For financial assets that are considered to be credit-impaired on purchase or origination, the effective interest rate (see Chapter 46) is calculated taking into account the initial lifetime expected credit losses in the estimated cash flows. [IFRS 9.B5.4.7, IFRS 9 Appendix A, IFRS 9.BC5.214, IFRS 9.BC5.217]. This is consistent with the original method for measuring impairment proposed in the 2009 exposure draft.

Consequently, no allowance is recorded for 12-month expected credit losses for financial assets that are credit-impaired on initial recognition. The rationale for not recording a 12-month expected credit loss allowance for these assets is that the losses are already reflected in the fair values at which they are initially recognised. The same logic could be applied to all the other financial assets which are not credit-impaired, arguing that they, too, are initially recognised at a fair value that reflects expectations of future losses. However, the distinction is made because the double-counting of 12-month expected credit losses on initial recognition would be too large for assets with such a high credit risk at initial recognition, for which default may have already occurred and the 12-month expected credit losses are already reflected in the initial fair value. The exclusion of initial expected credit losses from the computation of the effective interest rate would lead to a distortion that would be too significant to be acceptable.

For financial assets that were credit-impaired on purchase or origination, the credit-adjusted effective interest rate is also used subsequently to discount the expected credit losses. In subsequent reporting periods an entity is required to recognise:

- In the statement of financial position, the cumulative changes in lifetime expected credit losses since initial recognition, discounted at the credit-impaired effective interest rate (see section 5.7 below), as a loss allowance. [IFRS 9.5.5.13, IFRS 9.B5.5.45].
- In profit or loss, the amount of any change in lifetime expected credit losses as an impairment gain or loss. An impairment gain is recognised if favourable changes result in the lifetime expected credit losses estimate becoming lower than the original estimate that was incorporated in the estimated cash flows on initial recognition when calculating the credit-adjusted effective interest rate. [IFRS 9.5.5.14].

For favourable changes that result in lower lifetime expected credit losses than the original estimate on initial recognition, IFRS 9 does not provide guidance on where in the statement of financial position the debit entry is booked. In our view, the impairment gain is recognised as a direct adjustment to the gross carrying amount. This is supported by the application guidance in IFRS 9 on revision of estimates which requires adjusting the gross carrying amount of the financial asset. [IFRS 9.B5.4.6]. For purchased or originated credit-impaired financial assets, since the expected credit losses are included in the estimated cash flows when calculating the credit-adjusted effective interest rate, it would be consistent to follow the same principle and adjust the gross carrying amount when revising the original estimates of expected credit losses. An alternative treatment would be to recognise a negative loss allowance which would reflect the favourable changes in lifetime expected credit losses.

How we see it

For purchased or originated credit-impaired financial assets, if there are favourable changes that result in a lower lifetime expected credit losses than the original estimate on initial recognition, entities can recognise the impairment gain either as a direct adjustment to the gross carrying amount or as negative loss allowance.

Along with the other credit risk disclosures requirements (see section 15 below and Chapter 50), the holder is required to explain how it has determined that assets are credit-impaired (including the inputs, assumptions and estimation techniques used). It is also required to disclose the total amount of undiscounted expected credit losses at initial recognition for financial assets initially recognised during the reporting period that were purchased or originated credit-impaired. [IFRS 7.35H(c)].

Once a financial asset is classified as purchased or originated credit-impaired, it retains that classification until it is derecognised, i.e., when fully paid or written-off. The financial asset is never subject to a staging assessment and is required to be disclosed separately from financial assets that are subject to the general approach staging model. Therefore, a purchased or originated credit-impaired financial asset can never return to stage 1, even if the credit risk on the loan significantly improves.

The accounting treatment for a purchased credit-impaired financial asset is illustrated in the following illustration.

Illustration 3-1: Calculation of the credit-adjusted effective interest rate and recognition of a loss allowance for a purchased credit-impaired financial asset

On 1 January 20X1, Company D issued a bond that required it to pay an annual coupon of CU800 in arrears and to repay the principal of CU10,000 on 31 December 20Y0. By 20X6, Company D was in significant financial difficulties and was unable to pay the coupon due on 31 December 20X6. On 1 January 20X7, Company V estimates that the holder could expect to receive a single payment of CU4,000 at the end of 20X8. It acquires the bond at an arm's length price of CU3,000. Company V determines that the debt instrument is credit-impaired on initial recognition, because of evidence of significant financial difficulty of Company D and because the debt instrument was purchased at a deep discount.

It can be shown that using the contractual cash flows (including the CU800 overdue) gives rise to an effective interest rate of 70.1% (the net present value of CU800 now and annually thereafter until 20Y0 and CU10,000 receivable at the end of 20Y0 equals CU3,000 when discounted at 70.1%). However, because the bond is credit-impaired, Company V calculates the effective interest rate using the estimated cash flows of the instrument. In this case, the effective interest rate is 15.5% (the net present value of CU4,000 receivable in two years equals CU3,000 when discounted at 15.5%).

All things being equal, interest income of CU465 ($\text{CU3,000} \times 15.5\%$) would be recognised on the instrument during 20X7 and its carrying amount at the end of the year would be CU3,465 ($\text{CU3,000} + \text{CU465}$). However, if at the end of the year, based on reasonable and supportable evidence, the cash flow expected to be received on the instrument had increased to, say, CU4,250 (still to be received at the end of 20X8), an adjustment would be made to the asset's amortised cost. Accordingly, its carrying amount would be increased to CU3,681 ($\text{CU4,250 discounted over one year at } 15.5\%$) and an impairment gain of CU216 would be recognised in profit or loss.

On the other hand, if at the end of the year, based on reasonable and supportable evidence, the cash flow expected to be received on the instrument had decreased to, say, CU3,500 (still to be received at the end of 20X8), an adjustment would be made to the asset's amortised cost. Accordingly, its carrying amount would be decreased to CU3,031 ($\text{CU3,500 discounted over one year at } 15.5\%$) and an impairment loss of CU434 would be recognised in profit or loss.

4 Impairment for corporates

For corporates, their trade receivables and contract assets are often short term in nature and so qualify for the practical expedients available under IFRS 9. These include the use of the simplified approach and a provision matrix, which help in measuring the loss allowance for short-term trade receivables: [IFRS 9.B5.5.35]

- The simplified approach does not require the tracking of changes in credit risk, but instead requires the recognition of lifetime expected credit losses at all times. [IFRS 9.5.5.15]. For trade receivables or contract assets that do not contain a significant financing component (see section 10.1 below), entities are required to apply the simplified approach. [IFRS 9.5.5.15(a)(i)]. For trade receivables or contract assets that do contain a significant financing component, and lease receivables (see section 10.2 below), entities have a policy choice to apply either the simplified approach (see section 3.2 above) or the general approach (see section 3.1 above). For other debt instruments like bonds or longer-term loan receivables, the general approach is required.
- IFRS 9 allows using a provision matrix as a practical expedient for determining expected credit losses on trade receivables (see section 10.1 below). Many corporates may already use a provision matrix to calculate their current impairment allowance, but they would need to calculate expected credit losses for receivables that are not yet delinquent and also consider how they can incorporate forward-looking information into their historical customer default rates (see section 5.9.3 below). Entities would also need to group receivables into various customer segments that have similar loss patterns (e.g., by geography, product type, customer rating or type of collateral) (see section 6.5 below).

The IFRS 9 expected credit loss model can present challenges for the measurement of other assets for which the general model applies. These include long-term trade receivables and contract assets for which the simplified approach is not applied, lease receivables and debt securities which are measured at amortised cost or at fair value through other comprehensive income (see section 9 below). For example, for debt securities classified as measured at fair value through other comprehensive income (see Chapter 44), the corporate would be required to recognise a loss allowance based on 12-month expected credit losses, even for debt securities that are highly rated (e.g., AAA- or AA-rated bonds).

Under the general approach, at each reporting date, an entity is required to assess whether there has been a significant increase in credit risk since initial recognition as this will determine whether 12-month expected credit losses or lifetime expected credit losses are recognised (see section 6 below). When applying the general approach, a number of operational simplifications and presumptions are available to help entities assess significant increases in credit risk since initial recognition. These include:

- If a financial instrument has low credit risk (equivalent to investment grade quality), then an entity may assume no significant increases in credit risk have occurred (see section 6.4.1 below). The low credit risk simplification may be useful for corporates as it provides relief for entities from tracking changes in the credit risk of high quality financial instruments. However, collateral does not influence whether a financial instrument has a low credit risk.
- If more forward-looking information (either on an individual or collective basis) is not available, there is a rebuttable presumption that credit risk has increased significantly when contractual payments are more than 30 days past due (see section 6.2.2 below). However, contract assets, by definition, cannot be past due. Therefore, corporates cannot rely on delinquency for staging of such assets.
- The change in risk of a default occurring in the next 12 months may often be used as an approximation for the change in risk of a default occurring over the remaining life when assessing significant increase in credit risk (see section 6.4.3 below).
- The assessment may be made on a collective basis (see section 6.5 below) or at the counterparty level (see section 6.4.4 below).

In measuring expected credit losses, financial institutions often already have sophisticated expected credit loss models and systems for capital adequacy purposes, including data such as the probability of default, loss given default and exposure at default. Many non-financial entities do not have models and systems in place that capture such information. One possibility is to make use of credit default swap spreads and bond spreads. For financial instruments that are rated by an external agency such as Standard & Poor's, for example, listed bonds, an entity may be able to use, as a starting point, historical default rates implied by such ratings. It must be stressed that the historical default rates implied by credit ratings assigned by agencies are historical rates for corporate debt and so they would not, without adjustment, satisfy the requirements of IFRS 9 as the standard requires the calculation of expected credit losses, based on current conditions and forecasts of future conditions, to be based on reasonable and supportable information. A significant challenge in applying the IFRS 9 impairment requirements to quoted bonds is that the historical experience of losses by rating grade can differ significantly from the view of the market, as reflected in, for instance, credit default swap spreads and bond spreads.

Even for debt instruments that are not rated, it may be possible for entities to measure expected credit losses by estimating how external rating agencies would rate that instrument and using external rating agency loss data as an input. See Illustration 5-2 in section 5.4.1 below.

Bank deposits and current accounts that are classified as financial assets measured at amortised cost, are also subject to the general approach, even if treated as cash and cash equivalents. However, for most such instruments, given their maturity, the 12-month and lifetime expected credit losses are the same and will usually be small.

For any corporate that is a lessor, there may be a significant increase in allowances on finance leases, particularly if they chose to apply the simplified approach and record lifetime allowances (see section 10.2 below).

If the entity prepares separate financial statements under IFRS accounting standards, then the expected credit loss model will also apply to intercompany loans (see section 13 below). If revolving credit facilities are in place, then the entity will need to consider the period over which to measure expected credit losses and the portion of the undrawn revolving credit facility at the reporting date that is expected to be drawn down at the time of default in any period (limited, for facilities in stage 1 to the next twelve months) (see section 12 below). Corporates will also need to determine whether guarantees and other credit-enhancements can be reflected directly in the measurement of expected credit losses (see section 5.8.1 below).

The impairment disclosures required by IFRS 7 include inputs, assumptions and estimation methods used, operating simplifications applied and credit risk disclosures for trade receivables, contract assets or lease receivables measured under the simplified approach. The objective of the expanded disclosures is to enable users to understand the effect of credit risk on the amount, timing, and uncertainty of future cash flows (see section 15 below).

5 Measurement of expected credit losses

IFRS 9 defines credit loss as “the difference between all contractual cash flows that are due to an entity in accordance with the contract and all the cash flows that the entity expects to receive (i.e., all cash shortfalls), discounted at the original effective interest rate (or credit-adjusted effective interest rate for purchased or originated credit-impaired financial assets)”. When estimating the cash flows, an entity is required to consider: *[IFRS 9 Appendix A]*

- All contractual terms of the financial instrument (including prepayment, extension, call and similar options) over the expected life (see section 5.5 below) of the financial instrument. The maximum period to consider when measuring expected credit losses is the maximum contractual period (including extension options at the discretion of the borrower) over which the entity is exposed to credit risk (with an exception for revolving facilities).
- Cash flows from the sale of collateral held (see section 5.8.2 below) or other credit enhancements that are integral to the contractual terms.

Also, IFRS 9 goes on to define expected credit losses as “the weighted average of credit losses with the respective risks of a default occurring as the weights”. *[IFRS 9 Appendix A]*. However, IFRS 9 does not prescribe specific approaches to estimate expected credit losses, but provides guidance on what the approaches must entail: *[IFRS 9.5.5.17]*

Extract from IFRS 9

- 5.5.17** An entity shall measure expected credit losses of a financial instrument in a way that reflects:
- (a) an unbiased and probability-weighted amount that is determined by evaluating a range of possible outcomes;
 - (b) the time value of money; and
 - (c) reasonable and supportable information that is available without undue cost or effort at the reporting date about past events, current conditions and forecasts of future economic conditions.

5.1 Definition of default

Extract from IFRS 9

- B5.5.37** When defining default for the purposes of determining the risk of a default occurring, an entity shall apply a default definition that is consistent with the definition used for internal credit risk management purposes for the relevant financial instrument and consider qualitative indicators (for example, financial covenants) when appropriate. However, there is a rebuttable presumption that default does not occur later than when a financial asset is 90 days past due unless an entity has reasonable and supportable information to demonstrate that a more lagging default criterion is more appropriate. The definition of default used for these purposes shall be applied consistently to all financial instruments unless information becomes available that demonstrates that another default definition is more appropriate for a particular financial instrument.

Default is not defined in IFRS 9 (see extract above) for the purposes of determining the risk of a default occurring. Because it is defined differently by different institutions (for instance, 30, 90 or 180 days past due), the IASB was concerned that defining default could result in a definition that is inconsistent with that applied internally for credit risk management. In particular, since default is the anchor point used to measure probabilities of default and losses given default in Basel modelling, requiring a different definition would require building a different set of models for accounting purposes. Therefore, IFRS 9 requires an entity to apply a definition of default that is consistent with how it is defined for normal credit risk management practices, consistently from one period to another. It follows that an entity might have to use different default definitions for different types of financial instruments. However, IFRS 9 stresses that an entity needs to consider qualitative indicators of default when appropriate in addition to days past due, such as breaches of covenants. *[IFRS 9.B5.5.37]*.

The IASB did not originally expect expected credit loss calculations to vary as a result of differences in the definition of default, because of the counterbalancing interaction between the way an entity defines default and the credit losses that arise as a result of that definition of default. [IFRS 9.BC5.248]. For instance, if an entity uses a shorter delinquency period of 30 days past due instead of 60 days past due, the associated loss given default will be correspondingly smaller as it is to be expected that more debtors that are 30 days past due will in due course recover. However, the notion of default is fundamental to the application of the model, particularly because it affects the subset of the population that is subject to the 12-month expected credit loss measure. [IFRS 9.BC5.249]. IFRS 9 restricts diversity resulting from this effect by establishing a rebuttable presumption that default does not occur later than when a financial asset is 90 days past due. This presumption may be rebutted only if an entity has reasonable and supportable information to support an alternative default criterion. [IFRS 9.B5.5.37, IFRS 9.BC5.252].

A 90-day default definition would also be consistent with that used by banks for the advanced Basel II regulatory capital calculations (with a few exceptions).

How we see it

We observe that most banks have aligned their regulatory and accounting definitions of default. This generally means using 90 days past due under IFRS 9, with some exceptions for certain portfolios, such as mortgages, for which the regulatory definition may allow longer delinquency periods. Most banks have also aligned the accounting definition of credit-impaired for the purposes of transfers to stage 3 with the definition of default.

5.2 Lifetime expected credit losses

IFRS 9 defines lifetime expected credit losses as the expected credit losses that result from all possible default events over the expected life of a financial instrument, i.e., an entity needs to estimate the risk of a default occurring on the financial instrument during its expected life. [IFRS 9 Appendix A, IFRS 9.B5.5.43]. The expected life considered for the measurement of lifetime expected credit losses cannot be longer than the maximum contractual period (including extension options at the discretion of the borrower) over which the entity is exposed to credit risk. However, there is an exception for revolving facilities (see section 12 below).

Extract from IFRS 9

B5.5.29 For financial assets, a credit loss is the present value of the difference between:

- (a) the contractual cash flows that are due to an entity under the contract; and
- (b) the cash flows that the entity expects to receive.

Expected credit losses are estimated based on the present value of all cash shortfalls over the remaining expected life of the financial asset (see extract above). As expected, credit losses take into account both the amount and the timing of payments, a credit loss arises even if the holder expects to receive all the contractual payments due, but at a later date. [IFRS 9.B5.5.28, IFRS 9.B5.5.29].

When estimating lifetime expected credit losses for undrawn loan commitments (see section 11 below), the provider of the commitment needs to:

- Estimate the expected portion of the loan commitment that will be drawn down over the expected life of the loan commitment. Except for revolving facilities (see section 12 below), the expected life will be capped at the maximum contractual period, including extension options at the discretion of the borrower, over which the entity is exposed to credit risk (see section 5.3 below for 12-month expected credit losses). [IFRS 9.B5.5.31].
- Calculate the present value of cash shortfalls between the contractual cash flows that are due to the entity if the holder of the loan commitment draws down that expected portion of the loan and the cash flows that the entity expects to receive if that expected portion of the loan is drawn down. [IFRS 9.B5.5.30].

For a financial guarantee contract (see section 11 below), the guarantor is required to make payments only in the event of a default by the debtor in accordance with the terms of the instrument that is guaranteed. Accordingly, the estimate of lifetime expected credit losses would be based on the present value of the expected payments to reimburse the holder for a credit loss that it incurs, less any amounts that the guarantor expects to receive from the holder, the debtor, or any other party. If an asset is fully guaranteed, the expected credit loss estimate for the financial guarantee contract would be consistent with the estimated cash shortfall estimate for the asset subject to the guarantee. [IFRS 9.B5.5.32].

5.3 12-month expected credit losses

12-month expected credit losses are defined as “the portion of the lifetime expected credit losses that represent the expected credit losses that result from default events on a financial instrument that are possible within the 12 months after the reporting date”. [IFRS 9 Appendix A]. 12-month expected credit losses are further defined in IFRS 9.B5.5.43: [IFRS 9.B5.5.43]

Extract from IFRS 9

B5.5.43 For lifetime expected credit losses, an entity shall estimate the risk of a default occurring on the financial instrument during its expected life. 12-month expected credit losses are a portion of the lifetime expected credit losses and represent the lifetime cash shortfalls that will result if a default occurs in the 12 months after the reporting date (or a shorter period if the expected life of a financial instrument is less than 12 months), weighted by the probability of that default occurring. Thus, 12-month expected credit losses are neither the lifetime expected credit losses that an entity will incur on financial instruments that it predicts will default in the next 12 months nor the cash shortfalls that are predicted over the next 12 months.

Because the calculation is based on the probability of default, IFRS 9 emphasises that the 12-month expected credit loss is not the lifetime expected credit loss that an entity will incur on assets that it predicts will default in the next 12 months (i.e., for which the probability of default over the next 12 months is greater than 50%). For instance, the probability of default might be only 5%, in which case this is used to calculate 12-month expected credit losses, even though it is not probable that the asset will default. Also, the 12-month expected credit losses are not the cash shortfalls that are predicted over only the next 12 months. For an asset defaulting in the next 12 months, the lifetime expected credit losses that need to be included in the calculation will normally be significantly greater than just the cash flows that were contractually due in the next 12 months.

If the financial instrument has a maturity of less than 12 months, then the 12-month expected credit losses are the credit losses expected over the period to maturity.

For undrawn loan commitments (see section 11 below), an entity's estimate of 12-month expected credit losses are based on its expectations of the portion of the loan commitment that will be drawn down within 12 months of the reporting date. [IFRS 9.B5.5.31].

As already mentioned in section 1.2 above, the IASB believes that 12-month expected credit losses serve as a proxy for the recognition of initial expected credit losses over time, as proposed in the 2009 exposure draft, and they mitigate the systematic overstatement of interest revenue that was recognised under IAS 39. [IFRS 9.BC5.135]. This practical approximation was necessary as a result of the decision to decouple the measurement and allocation of initial expected credit losses from the determination of the effective interest rate following the re-deliberations of the 2009 exposure draft. [IFRS 9.BC5.199].

The stage 1, 12-month allowance overstates the necessary allowance for each financial instrument after initial recognition. However, this is offset by the fact that the allowance is not further increased (except for changes in the 12-month expected credit losses) until the instrument's credit risk has significantly increased and it is transferred to stage 2. For a portfolio of instruments with various origination dates, the overall provision may (very approximately) be a similar size as might be achieved using a more conceptually robust approach. Although there is no conceptual justification for an allowance based on 12-month expected credit losses, it was designed to be a pragmatic solution to achieve an appropriate balance between faithfully representing the underlying economics of a transaction and the cost of implementation.

How we see it

How accurate a proxy the 12-month and lifetime expected credit loss model is for a more conceptually pure approach will depend on the nature of the portfolio. Also, the effect of recording a 12-month expected credit loss in the first reporting period that a financial instrument is recognised will not have a significant effect on reported income if the portfolio is stable in size from one period to the next. The 12-month expected credit loss allowance may, however, significantly reduce the reported income for entities which are expanding the size of their portfolio.

Although the choice of 12 months is arbitrary, it is the same time horizon as used for the more advanced bank regulatory capital calculation under the Basel framework.⁹ The definition of 12-month expected credit losses is similar to the Basel Committee's definition of expected credit loss, although the modelling requirements differ significantly.¹⁰ The 12-month requirement under IFRS 9 will always differ from that computed for regulatory capital purposes, as the IFRS 9 measure is a point-in-time estimate, reflecting currently forecast economic conditions (see section 5.9.3 below), while the Basel regulatory figure is usually based on through-the-cycle assumptions of default and conservative estimates of losses given default. However, banks that use an advanced approach to calculate their capital requirements can use their existing systems and methodologies as a starting point and make the necessary adjustments to flex the calculation to comply with IFRS 9.

As mentioned above, the 12-month expected credit losses is defined as a portion of the lifetime expected credit losses that represent the expected credit losses that result from default events on a financial instrument that are possible within the 12 months after the reporting date. [IFRS 9 Appendix A]. When measuring 12-month expected credit losses, one question is whether the cash shortfalls used take into account only default events within the next 12 months or subsequent default events as well. The issue arises for instruments that are expected to default and cure (i.e., to restore to performing) and then default again after curing.

IFRS 9 does not explicitly mention the treatment of cures and subsequent defaults when calculating expected credit losses. However, the IFRS Transition Resource Group for Impairment of Financial Instruments briefly talked about this in their discussion about the life of revolving credit card portfolios in April 2015: "As regards assets in Stage 2, it was acknowledged that the probability of assets defaulting and curing would have to be taken into account and that it would be necessary to build this into any models dealing with expected credit loss calculations. However, it was noted that materiality would need to be considered."¹¹

How we see it

We conclude from the IFRS Transition Resource Group for Impairment of Financial Instruments discussion that cure events are only reflected in the calculation of the loss given default to the extent that they are expected to be effective. Consequently, if it is predicted that the asset will re-default in subsequent years, the re-default need not be included in the calculation of 12-month expected losses if the defaults are expected to be unrelated to the first default. In practice, however, IFRS 9 acknowledges that a variety of techniques can be used to meet the objective of expected credit loss measurement and that the definition of default may vary by product, across a bank and between banks.

When measuring expected credit losses, the treatment of re-defaults affects both the probability of default and the loss given default. Therefore, the same treatment is applied consistently to determine both the probability of default and the loss given default.

5.4 Probability of default and loss rate approaches

As mentioned above, the impairment requirements as per IFRS 9.5.1 do not prescribe specific approaches to estimate expected credit losses. Some of the common approaches include the PD and loss rate approaches (see sections 5.4.1 and 5.4.2 below, respectively).

5.4.1 Probability of default approach

Following from Illustration 1-1 in section 1.2 above, calculations of the 12-month and lifetime expected credit losses are illustrated below.

Illustration 5-1: 12-month and lifetime expected credit loss measurement based on a probability of default approach

On 31 December 20X1, Bank A originates a 10 year bullet loan with a gross carrying amount of CU1,000,000, with interest being due at the end of each year and the principal due at maturity. In line with IFRS 9, Bank A must recognise an impairment allowance for the expected credit losses, considering current and forward-looking credit risk information.

The expected credit losses are a probability-weighted estimate of the present value of estimated cash shortfalls - i.e., the weighted average of credit losses, with the respective risks of a default occurring used as the weights. For this purpose, the following parameters must be estimated:

- Probability of default (PD) - Estimate of the likelihood of default over a given time horizon (e.g., from t_{i-1} to t_i). A default may only happen at a t_i horizon if the facility has not been previously derecognized and is still in the portfolio. An early exit ('EE') may occur in case of default unless the facility reverts to performing without significant modification of the contractual terms. The marginal probability of default for the period t_{i-1} to t_i is then adjusted from the probability that an early exit occurred during the previous periods:

$$PD_{t_i} \times \prod_{j=1}^{j=i-1} (1 - EE_{t_j})$$

We note that, for simplicity, Bank A may decide to model *EE* within the PD component.

- Loss given default (LGD) - Estimate of the loss arising in case a default occurs at a given time (e.g., t_i). It is based on the difference between the contractual cash flows due and those that the lender would expect to receive, including from the realisation of any collateral. It is usually expressed as a percentage of the EAD.
- Exposure at default (EAD) - Estimate of the exposure at a future default date, taking into account expected changes in the exposure after the reporting date, including repayments of principal and interest, whether scheduled by contract or otherwise, expected drawdowns on committed facilities, and accrued interest from missed payments.
- Discount rate (r) - Rate used to discount an expected loss to a present value at the reporting date, i.e., the effective interest rate.

Based on these parameters, an expected credit loss can be computed for any horizon - typically for each due date of an exposure. The computation formula can be expressed as follows:

$$ECL_{t_n} = \sum_{t_i=t_1}^{t_i=t_n} \frac{PD_{t_i} \times \prod_{j=1}^{j=i-1} (1 - EE_{t_j}) \times LGD_{t_i} \times EAD_{t_i}}{(1 + r_i)^{t_i}}$$

Where:

- i = each future payment
- t_i = maturity of the payment i
- t_n = horizon considered (either 12-month or lifetime)

Note that the figures in the tables below have been rounded to one or two decimal points.

Stage 1: 12-month expected credit losses of CU422

At origination, the loan is in stage 1. Thus, a corresponding 12-month expected credit loss allowance is recognised, i.e., the portion of the lifetime expected credit losses that result from default events that are possible within 12 months after the reporting date.

Based on statistical and qualitative information, Bank A has computed the following expected credit loss parameters at origination:

- As interest is paid on a yearly basis, expected credit losses are calculated using annual periods.
- Each year, exposure at default equals the outstanding principal plus accrued interest due at the end of the year. This bullet loan does not allow any prepayment, therefore the exposure at default is constant.
- The effective interest rate of the loan is assumed to be the contractual rate, which is 3%.
- Bank A sets $EE = PD_{n-1} \times 0.8$, on the basis that a proportion of the loans which default are expected to cure and will once again be at risk of default.
- Based on provided guarantees and collateral, loss given default is estimated at 25% of EAD, whatever the date of default.

Year	Exposure at default	Discount rate	Cumulative probability of default @ origination	Marginal probability of default	Cumulative EE t-1 @ origination	Loss given default	Marginal expected credit loss	
	CU						CU	
20X1	1,000,000							
20X2	1,030,000	3%	0.17%	0.17%	0.00%	25%	422	12m expected credit loss
20X3	1,030,000	3%	0.49%	0.32%	0.14%	25%	775	
20X4	1,030,000	3%	0.86%	0.37%	0.39%	25%	877	
20X5	1,030,000	3%	1.38%	0.53%	0.69%	25%	1,196	
20X6	1,030,000	3%	1.84%	0.47%	1.11%	25%	1,027	
20X7	1,030,000	3%	2.37%	0.54%	1.47%	25%	1,141	
20X8	1,030,000	3%	2.85%	0.49%	1.90%	25%	1,014	
20X9	1,030,000	3%	3.30%	0.46%	2.28%	25%	912	
20Y0	1,030,000	3%	3.84%	0.56%	2.64%	25%	1,073	
20Y1	1,030,000	3%	4.50%	0.69%	3.07%	25%	1,280	
							9,717	Lifetime expected credit loss

$$\text{Marginal PD}_i = 1 - \frac{1 - \text{Cum PD}_i}{1 - \text{Cum PD}_{i-1}}$$

$$\text{Marginal ECL}_i = \frac{\text{PD}_i \times (1 - \text{Cum EE}_{i-1}) \times \text{LGD}_i \times \text{EAD}_i}{(1 + r_i)^i}$$

Stage 2: Lifetime expected credit losses of CU50,285

On 31 December 20X4 - 3 years after origination, the loan shows signs of significant deterioration in credit quality based on the creditworthiness of the obligor and forward-looking information, and Bank A moves it to stage 2. Illustration 6-4 in section 6.2.4 below shows the calculation underlying this assessment.

Consistent with the significant increase in credit risk, the probability of default of the obligor has increased. In consequence, the probability of an early exit has also increased, because of the higher level of default. For the purposes of this example, we assume that there are no significant fluctuations in collateral values and the loss given default remains constant.

Year	Exposure at default	Discount rate	Cumulative probability of default	Marginal probability of default	Cumulative EE t-1	Loss given default	Marginal expected credit loss	
	CU						CU	
20X4	1,000,000		0.00%					
20X5	1,030,000	3%	1.40%	1.40%	0.00%	25%	3,495	12m expected credit loss
20X6	1,030,000	3%	3.87%	2.51%	1.12%	25%	6,017	
20X7	1,030,000	3%	8.82%	5.15%	3.10%	25%	11,756	
20X8	1,030,000	3%	12.84%	4.40%	7.06%	25%	9,366	
20X9	1,030,000	3%	16.04%	3.67%	10.27%	25%	7,322	
20Y0	1,030,000	3%	18.98%	3.50%	12.83%	25%	6,585	
20Y1	1,030,000	3%	21.60%	3.23%	15.18%	25%	5,745	
							50,285	Lifetime expected credit loss

Stage 3: Lifetime expected credit losses of CU262,850

In the following year, on 31 December 20X5, the obligor does not pay the amount due. Based on credit information available, it is already considered to be in default and is moved to stage 3 - credit-impaired. At this time, the exposure is CU1,030,000.

Once a facility becomes credit-impaired, impairment must still represent expected credit losses. Therefore, it must be probability-based. At the reporting date, Bank A updates the appraisal value of the collateral and considers 3 probable scenarios:

- **Scenario 1 - Cure:** The obligor eventually pays the amounts past due and the loan reverts to performing. In this case, expected credit losses correspond to lifetime losses expected from loans that have recently defaulted. Based on its historical data and using the methodology described above, Bank A expects an expected credit loss of CU130,000.
- **Scenario 2 - Restructure:** Bank A comes to a restructuring agreement with the obligor. After 6 months of negotiation, the loan is written off and a new loan is initiated with a net present value of CU800,000.
- **Scenario 3 - Liquidation:** The loan is written off and the bank starts the collection of the contractual collateral. Bank A expects to sell the collateral within a year and to collect CU700,000 net of recovery costs.

The expected credit loss of each scenario can be calculated as follows:

$$ECL = EAD - \sum_{t_i=t_1}^{t_i=t_n} \frac{CF_{t_i} - RC_{t_i}}{(1 + r_i)^{t_i}}$$

Where:

<i>ECL</i>	= expected credit loss
<i>CF</i>	= expected future cash flows
<i>RC</i>	= expected recovery costs

Probable scenarios	Probability	EAD	Dis-count rate	Expected net future cash flows	Expected recovery time	Expected credit loss of each scenario	Weighted expected credit loss
		CU		CU		CU	CU
Scenario 1: Cure	20%	1,030,000	3%	900,000	0.0	130,000	26,000
Scenario 2: Restructure	40%	1,030,000	3%	800,000	0.5	241,737	96,695
Scenario 3: Liquidation	40%	1,030,000	3%	700,000	1.0	350,388	140,155
Weighted average expected credit loss						Lifetime expected credit loss	262,850
						% of EAD:	26%

$$ECL = EAD - \frac{\text{Exp. Net future CF}}{(1+r)^{\text{exp recovery time}}}$$

How we see it

Our observation of practice suggests that most sophisticated banks have developed their IFRS 9 solutions by adjusting and extending their Basel regulatory capital models. This is true for all types of model component: probability of default, loss given default and exposure at default. This is perhaps unsurprising given the historical investment large banks have made in their Basel models, and the fact that IFRS 9 shares fundamental similarities in expected loss modelling. But, for many banks, creating lifetime estimates and altering models to satisfy the complex and detailed expected credit loss impairment requirements on first application of IFRS 9 necessitated significant work on initial adoption and as the approach to ECL modelling continues to evolve.

However, many non-financial entities do not have models and systems in place that capture such information. One possibility is to make use of historical default rates as collected by credit rating agencies such as Standard and Poor's. This is shown in the Illustration below.

Illustration 5-2: Expected credit loss measurement using credit rating agency historical default rates

Introduction

A corporate uses a non-modelled approach to quantify the expected credit loss of a loan issued to Borrower X.

Fact Pattern

On 1 January 20X2, the corporate made a 2-year loan of CU1.5m to Borrower X. It needs to estimate its expected credit losses on the loan for its financial statements for the year ended 31 December 20X2. There is no specified collateral pledged for this loan. The lender has a general security agreement in place for the loan but it is subordinate to other bank debts of Borrower X. As a result, the loan is considered to be unsecured for the purpose of the expected credit loss measurement.

Borrower X is an unrated private company. However, its financial condition is such that the loan would appear to fit what Standard & Poor's would rate as a B-rated instrument: the balance sheet of Borrower X indicates that while the entity currently has the capacity to meet its financial commitments on the obligation, adverse business, financial, or economic conditions will likely impair the borrower's capacity or willingness to meet its financial commitments on the obligation.

The loan is assessed to be in stage 1 as the lender determines that there has not been a significant increase in credit risk. However, the economic environment is more uncertain than has been typical over the course of the last decade.

Expected credit loss Projection

The corporate calculates the expected credit losses using the normal formula (expected credit loss = *probability of default × loss given default × exposure at default, discounted at the effective interest rate*):

- A probability of default is initially estimated based on the historical default rates for loans which have 'B' credit ratings. The S&P global ratings study indicates that 'B' rated entities have a historical aggregate cumulative 12-month probability of default of 3.18%.¹² Given the uncertainties in the economic environment this historical probability of default needs to be adjusted. The corporate adjusts the S&P historical default rate to reflect current conditions and estimates a 12-month probability of default range of 4-6%.
- Given the subordination of the loan to other bank debts, the majority of the amount owed would probably be lost in the event of default, therefore, loss given default is estimated in the range of 80-100%.
- The exposure at default is known, i.e., CU1.5m, and the effective interest rate of the loan for this example is assumed to be the contractual rate, which is 3%. As a simplifying assumption, it is also assumed that any default is most likely to occur at the end of the year. The discounted exposure at default over 1 year is CU1.5m which, divided by 1.03 give a discounted amount of approximately CU1.46m, that can be multiplied by the probability of default and the loss given default.

Conclusion

With the assumptions that the discount rate is 3%, the 1-year probability of default is 4-6% and the loss given default is 80-100%, the expected credit loss for the loan is estimated to be in the range of CU46,602 - CU87,379 (see table below). However, this approach clearly acknowledges that there is a range of possible values for the expected credit loss and significant judgement is required to reach a final determination. This judgement would need to be documented using all available information without undue cost or effort, possibly including the current spreads of similar bonds that are 'B' rated, to narrow the range of possible values for the expected credit loss.

		Loss given default (CU)	
		80%	100%
Probability of default	4%	46,602	58,252
	6%	69,903	87,379

5.4.2 Loss rate approach

Not every entity calculates a separate risk of a default occurring and a loss given default, but instead uses a loss rate approach. Using this approach, the entity develops loss-rate statistics on the basis of the amount written off over the life of the financial assets. It must then adjust these historical credit loss trends for current conditions and expectations about the future. The following Illustrative Example 9 from IFRS 9 is designed to illustrate how an entity measures 12-month expected credit losses using a loss rate approach. [IFRS 9.IE Example 9, IFRS 9.IE53-IE57].

Illustration 5-3: 12-month expected credit losses measurement based on a loss rate approach

Bank A originates 2,000 bullet loans with a total gross carrying amount of CU500,000. Bank A segments its portfolio into borrower groups (Groups X and Y) on the basis of shared credit risk characteristics at initial recognition. Group X comprises 1,000 loans with a gross carrying amount per client of CU200, for a total gross carrying amount of CU200,000. Group Y comprises 1,000 loans with a gross carrying amount per client of CU300, for a total gross carrying amount of CU300,000. There are no transaction costs and the loan contracts include no options (for example, prepayment or call options), premiums or discounts, points paid, or other fees.

Bank A measures expected credit losses on the basis of a loss rate approach for Groups X and Y. In order to develop its loss rates, Bank A considers samples of its own historical default and loss experience for those types of loans. In addition, Bank A considers forward-looking information, and updates its historical information for current economic conditions as well as reasonable and supportable forecasts of future economic conditions. Historically, for a population of 1,000 loans in each group, Group X's loss rates are 0.3%, based on four defaults, and historical loss rates for Group Y are 0.15%, based on two defaults.

¹² [S&P Global Ratings: Default, Transition, and Recovery: 2021 Annual Global Corporate Default and Rating Transition Study, Table 24 Global Corporate Average Cumulative Default Rates \(1981-2021\)](#), S&P Global, 13 April 2022. Available on S&P Global's website.

	Number of clients in sample	Estimated per client gross carrying amount at default	Total estimated gross carrying amount at default	Historic per annum average defaults	Estimated total gross carrying amount at default	Present value of observed loss (a)	Loss rate
Group	A	B	C = A × B	D	E = B × D	F	G = F ÷ C
X	1,000	CU200	CU200,000	4	CU800	CU600	0.30%
Y	1,000	CU300	CU300,000	2	CU600	CU450	0.15%

(a) Expected credit losses are discounted using the effective interest rate. However, for purposes of this example, the present value of the observed loss is assumed. [IFRS 9.5.5.17(b)].

At the reporting date, Bank A expects an increase in defaults over the next 12 months compared to the historical rate. As a result, Bank A estimates five defaults in the next 12 months for loans in Group X and three for loans in Group Y. It estimates that the present value of the observed credit loss per client will remain consistent with the historical loss per client.

On the basis of the expected life of the loans, Bank A determines that the expected increase in defaults does not represent a significant increase in credit risk since initial recognition for the portfolios. On the basis of its forecasts, Bank A measures the loss allowance at an amount equal to 12-month expected credit losses on the 1,000 loans in each group amounting to CU750 and CU675 respectively. This equates to a loss rate in the first year of 0.375% for Group X and 0.225% for Group Y.

	Number of clients in sample	Estimated per client gross carrying amount at default	Total estimated gross carrying amount at default	Expected defaults	Estimated total gross carrying amount at default	Present value of observed loss	Loss rate
Group	A	B	C = A × B	D	E = B × D	F	G = F ÷ C
X	1,000	CU200	CU200,000	5	CU1,000	CU750	0.375%
Y	1,000	CU300	CU300,000	3	CU900	CU675	0.225%

Bank A uses the loss rates of 0.375% and 0.225% respectively to estimate 12-month expected credit losses on new loans in Group X and Group Y originated during the year and for which credit risk has not increased significantly since initial recognition.

The example above illustrates that under the loss rate approach, an entity would compute its loss rates by segmenting its portfolio into appropriate groupings (or sub-portfolios) based on shared credit risk characteristics and then updating its historical loss information with more forward-looking information. The loss rate was derived simply by computing the ratio between the present value of observed losses (the numerator) and the gross carrying amount of the loans (the denominator).

Expected credit losses must be discounted at the effective interest rate. However, in this example, the present value of the observed loss is just assumed. This is an additional area of complexity that entities have to take into account when trying to build upon their existing loss rate approaches.

How we see it

Although the loss rate approach does not require an explicit calculation of the risk of a default occurring, there has to be an estimate of the number of defaults in order to determine whether there has been a significant increase in credit risk (see section 6 below). Hence, IFRS 9 also requires any entities that intend to use this approach to track the likelihood of default.

5.5 Expected life versus contractual period

Lifetime expected credit losses are defined as the expected credit losses that result from all possible default events over the expected life of a financial instrument. [IFRS 9 Appendix A]. This is consistent with the requirement that an entity assesses whether the credit risk on a financial instrument has increased significantly since initial recognition by using the change in the risk of a default occurring over the expected life of the financial instrument. [IFRS 9.5.5.9].

An entity must therefore estimate cash flows and the instrument's life by considering all contractual terms of the financial instrument (for example, prepayment, extension, call and similar options). There is a presumption that the expected life of a financial instrument can be estimated reliably. In those rare cases when it is not possible to reliably estimate the expected life of a financial instrument, the entity shall use the remaining contractual term of the financial instrument. [IFRS 9 Appendix A, IFRS 9.B5.5.51].

Extract from IFRS 9

5.5.19 The maximum period to consider when measuring expected credit losses is the maximum contractual period (including extension options) over which the entity is exposed to credit risk and not a longer period, even if that longer period is consistent with business practice.

[IFRS 9.5.5.19].

Although an exception to the maximum period to consider when measuring expected credit losses has been added for revolving facilities (see section 12 below), the IASB remains of the view that the contractual period over which an entity is committed to provide credit (or a shorter period considering prepayments) is the correct conceptual outcome. The IASB noted that most loan commitments will expire at a specified date, and if an entity decides to renew or extend its commitment to extend credit, it will be a new instrument for which the entity has the opportunity to revise the terms and conditions. [IFRS 9.BC5.260].

This means that extension options are only reflected in the measurement of expected credit losses as long as this does not extend the horizon beyond the maximum contractual period over which the entity is exposed to credit risk. Extension options at the discretion of the lender are therefore excluded from the measurement of expected credit losses. Similarly, a lender's ability to require prepayment limits the horizon over which it is exposed to credit risk. The first prepayment date at the discretion of the lender therefore represents the maximum period to be reflected in the expected loss calculation.

When assessing the impact of extension options at the discretion of the borrower, an entity estimates both the probability of exercise of the extension option as well as the portion of the loan that will be extended if the extension option can be exercised for a portion of the loan only. This is consistent with how lifetime expected losses must be assessed for loan commitments where an entity's estimate of expected credit losses must be consistent with its expectations of drawdowns on that loan commitment. Although IFRS 9 is not explicit on this point, the effect of extension options is best modelled not by estimating an average life of the facility but by estimating the exposure at default each year over the maximum lifetime. This is because use of an average life would not reflect losses expected to occur beyond the average life.

[IFRS 9.B5.5.31].

Expected prepayments at the discretion of borrowers are also reflected in the measurement of expected credit losses. As with extension options, an entity must estimate both the probability of exercise of the prepayment option as well as the portion of the loan that will be prepaid if the prepayment option can be exercised for a portion of the loan only. As with extension options, IFRS 9 does not specify whether prepayment patterns are reflected through an amortising exposure at default over the maximum contractual period of the financial instruments or, rather, by shortening the horizon over which to measure expected credit losses to the average life of the financial instruments.

How we see it

Similar to the treatment of extension options, for prepayment options, in our view it is more appropriate to adjust the EAD for the facility each year over the maximum lifetime, rather than to shorten the period over which to measure expected credit losses. We consider this a more transparent way of incorporating product features and potential impacts of different macroeconomic scenarios that can, for example, affect pre-payment patterns and customers' ability to refinance.

Further complexity in assessing expected prepayments and extensions arises if one considers that the behaviour of borrowers is affected by their creditworthiness. This means that prepayment and extension patterns are probably estimated separately for stage 1 and stage 2 assets. This may represent a significant challenge, as making such estimates would require distinct historical observations for each of the stage 1 and 2 populations, which are unlikely to be available given that these populations were never identified in the past. Prepayment assumptions for stage 2 assets would need to factor in the probabilities that some may subsequently default and some may cure. A further complication is that expected prepayment and extension behaviour may vary with changes in the macroeconomic outlook.

IFRS 9 is clear that for loan commitments and financial guarantee contracts, the time horizon to measure expected credit losses is the maximum contractual period over which an entity has a present contractual obligation to extend credit. [IFRS 9.B5.5.38]. However, for revolving credit facilities (e.g., credit cards and overdrafts), as an exception to the normal rule, this period is extended beyond the maximum contractual period and includes the period over which the entity is exposed to credit risk and expected credit losses would not be mitigated by credit risk management actions (see section 12 below). This exception is limited to facilities that include both a loan and an undrawn commitment component, that do not have a fixed term or repayment structure and usually have a short contractual cancellation period (for example, one day).

[IFRS 9.5.5.20, IFRS 9.B5.5.39, IFRS 9.B5.5.40].

Frequently asked questions

Question 5-1: What is the maximum period to consider when measuring expected credit losses for a portfolio of mortgage loans with a stated maturity but containing a contractual feature whereby the term is automatically extended subject to the lender's non-objection?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 22 April 2015 - Agenda paper no. 1)

At its April 2015 meeting, the IFRS Transition Resource Group for Impairment of Financial Instruments (see section 1.4 above) discussed how to determine the maximum period for measuring expected credit losses, by reference to the following example.

Illustration 5-4: Determining the maximum contractual period when measuring expected credit losses

Bank A manages a portfolio of variable rate mortgages on a collective basis. The mortgage loans are issued to retail customers in Country X with the following terms:

- The stated maturity is 6 months with an automatic extension feature whereby, unless the borrower or lender take action to terminate the loan at the stated maturity date, the loan automatically extends for the following 6 months. The interest rate is fixed for each 6-month period at the beginning of the period. The interest rate is reset to the current market interest rate on the extension date.
- The lender's right to refuse an extension is unrestricted.

It is assumed that the mortgage loans meet the criteria for amortised cost measurement under IFRS 9.4.1.2.

In practice, borrowers are generally expected not to elect to terminate their loans on the stated maturity date, because moving the mortgage to another bank, or applying for a new product, generally involves an administrative burden and has little or no economic benefit for the borrower.

Furthermore, Bank A does not complete regular credit file reviews for individual loans and as a result does not usually cancel the loans unless it receives information about an adverse credit event in respect of a particular borrower. On the basis of historical evidence, such loans extend many times and can last for up to 30 years.

The IFRS Transition Resource Group for Impairment of Financial Instruments noted that:

- IFRS 9 is clear that the maximum period to consider when measuring expected credit losses in this example would be restricted to 6 months, because this is the maximum contractual period over which the lender is exposed to credit risk, i.e., the period until the lender can next object to an extension. [IFRS 9.5.5.19].
- IFRS 9 requires that extension options must be considered when determining the maximum contractual period, but does not specify whether these are lender or borrower extension options. However, if the extension option is within the control of the lender, the lender cannot be forced to continue extending credit and therefore such an option cannot be considered as lengthening the maximum period of exposure to credit risk. Conversely, if a borrower holds an extension option that could force the lender to continue extending credit, this would have the effect of lengthening the maximum contractual period of credit exposure.
- The maximum contractual period over which the entity is exposed to credit risk should be determined in accordance with the substantive contractual terms of the financial instrument. To further illustrate this point, a situation in which a lender is legally prevented from exercising a contractual right should be seen as distinct from a situation in which a lender chooses not to exercise a contractual right for practical or operational reasons.

- In the example presented, the facility is not of a revolving nature and the borrower does not have any such flexibility regarding drawdowns. Consequently, it would not be appropriate to analogise the 6-month mortgage loan to a revolving credit facility that has been fully drawn at the reporting date. Hence, the example falls outside the narrow scope exception for revolving credit facilities (e.g., credit cards and overdraft facilities) in which the maximum period to consider when measuring expected credit losses is over the period that the entity is exposed to credit risk and expected credit losses would not be mitigated by credit risk management actions, even if that period extends beyond the maximum contractual period (see section 12 below). [IFRS 9.5.5.20].
- Consequently, it was acknowledged that there may be a disconnect between the accounting and credit risk management view in some situations (e.g., an entity may choose to continue extending credit to a long-standing customer despite being in a position to reduce or remove the exposure). See further discussion on the application of the revolving credit facilities exception to multi-purpose facilities (see section 12 below).

For demand deposits that have no fixed maturity and can be withdrawn by the holder on very short notice (e.g., one day, assuming there is no contractual or legal constraint that could prevent the holder from withdrawing its cash at any time), the period used by the holder of such demand deposits to estimate expected credit losses would be limited to the contractual notice period, i.e., one day. This is the maximum contractual period over which the holder is exposed to credit risk. In accordance with IFRS 9.5.5.19, extension periods at the option of the holder are excluded in estimating the maximum contractual period because the holder can unilaterally choose not to extend credit and thus can limit the period over which it is exposed to credit risk. Furthermore, demand deposits do not fall under the revolving credit facility exception (see section 12 below) as they do not comprise an undrawn element. [IFRS 9.5.5.20].

Similar requirements apply to loans that are subject to a rollover facility at the discretion of the lender, where the lender has an option to extend for a further period during the term of the facility but is not committed or contractually obliged to grant the extension (e.g., the lender has granted a 1-month loan and the lender has the option to extend for a further period over the 1-year rollover facility). The period considered by the lender when estimating expected credit losses including the determination of the probability of default (see section 5.4.1 above) would be limited to the contractual period. In such instances, the probability of default would be determined based on the contractual payment at the end of the maximum contractual period, i.e., 1-month rather than 1-year, should the lender not extend the facility. The resulting expected credit losses reflects the consequences of credit not being extended, although this could include the impact of a scenario where the loan is extended as part of the recovery process (see section 5.6 below).

5.6 Probability-weighted outcome and multiple scenarios

Expected credit losses must reflect an unbiased and probability-weighted estimate of credit losses over the expected life of the financial instrument (i.e., the weighted average of credit losses with the respective risks of a default occurring as the weights). [IFRS 9.5.5.17(a), IFRS 9 Appendix A, IFRS 9.B5.5.28].

IFRS 9 makes it clear that when measuring expected credit losses, in order to derive an unbiased and probability-weighted amount, an entity needs to evaluate a range of possible outcomes. [IFRS 9.5.5.17(a)]. This involves identifying possible scenarios that specify:

- The amount and timing of the cash flows for particular outcomes
- The estimated probability of these outcomes

Extract from IFRS 9

- 5.5.18 When measuring expected credit losses, an entity need not necessarily identify every possible scenario. However, it shall consider the risk or probability that a credit loss occurs by reflecting the possibility that a credit loss occurs and the possibility that no credit loss occurs, even if the possibility of a credit loss occurring is very low.
- B5.5.41 The purpose of estimating expected credit losses is neither to estimate a worst-case scenario nor to estimate the best-case scenario. Instead, an estimate of expected credit losses shall always reflect the possibility that a credit loss occurs and the possibility that no credit loss occurs even if the most likely outcome is no credit loss.

[IFRS 9.5.5.18, IFRS 9.B5.5.41].

Although an entity does not need to identify every possible scenario, it will need to take into account the possibility that a credit loss occurs, no matter how low that probability is. This is not the same as a single estimate of the worst-case or best-case scenario, or the most likely outcome (i.e., when there is a low risk or probability of default with high loss outcomes, the most likely outcome could be no credit loss even though an allowance would be required based on probability-weighted cash flows). It is worthwhile noting that it is implicit that the sum of the weighted probabilities will be equal to one. A simple example of application of a probability-weighted calculation is shown in Illustration 5-5 in section 5.6.1 below.

Without taking into account multiple economic scenarios, calculating a probability-weighted amount does not require a complex analysis or a detailed simulation of a large number of scenarios and IFRS 9 suggests that relatively simple modelling may be sufficient. For instance, the average credit losses of a large group of financial instruments with shared risk characteristics may be a reasonable estimate of the probability-weighted amount. In other situations, the identification of scenarios that specify the amount and timing of the cash flows for particular outcomes and the estimated probability of those outcomes will probably be needed. In those situations, the expected credit losses shall reflect at least two outcomes in accordance with IFRS 9.5.5.18.

[IFRS 9.B5.5.42].

5.6.1 Single versus multiple forward-looking economic scenarios

Frequently asked questions

Question 5-2: Whether, when measuring expected credit losses and when assessing significant increases in credit risk, can an entity use a single forward-looking economic scenario or whether an entity needs to incorporate multiple forward-looking scenarios, and if so how?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 11 December 2015 - Agenda paper no. 1)

At the December 2015 IFRS Transition Resource Group for Impairment of Financial Instruments meeting (see section 1.4 above), the question was asked as to whether the use of multiple scenarios referred to in IFRS 9 relates only to what might happen to particular assets given a single forward-looking economic scenario (i.e., default or no default), or whether application of IFRS 9 requires an entity to use multiple forward-looking economic scenarios, and if so how.

The IFRS Transition Resource Group for Impairment of Financial Instruments members noted that the measurement of expected credit losses is required to reflect an unbiased and probability-weighted amount that is determined by evaluating a range of possible outcomes. Consequently, when there is a non-linear relationship between the different forward-looking scenarios and their associated credit losses, using a single forward-looking economic scenario would not meet this objective. In such cases, more than one forward-looking economic scenario would need to be used in the measurement of expected credit losses.¹³ For each scenario the associated expected credit losses would need to be multiplied by the weighting allocated to that scenario.

The IFRS Transition Resource Group for Impairment of Financial Instruments also discussed the use of multiple economic scenarios to assess whether exposures should be measured using lifetime economic losses (see section 6.7 below). It was noted by the IFRS Transition Resource Group for Impairment of Financial Instruments that if the same variable is relevant for determining significant increase in credit risk and for measuring expected credit losses, the same forward-looking scenarios should be used for both.

The IFRS Transition Resource Group for Impairment of Financial Instruments discussed a particular example in which there are considered to be three possible economic scenarios.¹⁴ This is shown in the Illustration below.

Illustration 5-5: Incorporating single versus multiple forward-looking scenarios when measuring expected credit losses

Scenario	Future unemployment	Likelihood of occurrence	Expected credit losses
(a)	4%	20%	CU30
(b)	5%	50%	CU70
I	6%	30%	CU170

¹³ IASB Transition Resource Group for Impairment of Financial Instruments, [Meeting Summary](#), 11 December 2015, para. 49, 11. Available on the IFRS Foundation's website.

¹⁴ IASB Transition Resource Group for Impairment of Financial Instruments, [Meeting Summary](#), 11 December 2015, paras. 50 and 51. Available on the IFRS Foundation's website.

Use of a single central economic scenario based on the most likely outcome of 5% unemployment, i.e., scenario (b), would give rise to an expected credit loss of CU70. However, using a probability-weighted range of scenarios, the expected credit loss would be CU92 ((CU30 × 0.2) + (CU70 × 0.5) + (CU170 × 0.3)). Consequently, the IFRS Transition Resource Group for Impairment of Financial Instruments observed that in this example, using a single central forward-looking economic scenario would not result in an unbiased and probability-weighted amount in accordance with IFRS 9.

The IFRS Transition Resource Group for Impairment of Financial Instruments was concerned about the distribution of possible losses often being 'non-linear', in that the increase in losses associated with those economic scenarios that are worse than the central forecast will be greater than the reduction in losses associated with those scenarios that are more benign. To use statistical terminology, the distribution is skewed. Depending on how it is calculated, a single scenario gives the mode of this distribution (i.e., the most likely outcome) or the median (i.e., the central forecast). In contrast, IFRS 9 requires the use of the mean (i.e., a probability-weighted estimation).

We have illustrated a possible distribution of the losses in the portfolio consistent with the above example in Figure 5-1 below.

Figure 5-1: Distribution of losses

At the IFRS Transition Resource Group for Impairment of Financial Instruments meeting, it was noted that there are a number of possible approaches that might be used to incorporate multiple economic approaches. IFRS 9 does not prescribe any particular method of measuring expected credit losses and the measurement should reflect an entity's own view, however, IFRS 9 requires that the expected losses must reflect:

- An unbiased and probability-weighted amount that is determined using a range of possible outcomes
- Reasonable and supportable information that is available without undue cost or effort at the reporting date

With respect to reasonable and supportable information, IFRS Transition Resource Group for Impairment of Financial Instruments members made the following observations:

- Although IFRS 9 does not specifically require an entity to consider external information, an entity should consider information from a variety of sources in order to ensure that the information used is reasonable and supportable.
- The information considered could vary depending on the facts and circumstances including the level of sophistication of the entity, geographical region and the particular features of the portfolio.
- While entities are not expected to consider every possible scenario, the scenarios considered should reflect a representative sample of possible outcomes.¹⁵

The IFRS Transition Resource Group for Impairment of Financial Instruments members recognised that materiality considerations would need to be taken into account.

¹⁵ IASB Transition Resource Group for Impairment of Financial Instruments, [Meeting Summary](#), 11 December 2015, paras. 53. Available on the IFRS Foundation's website.

In an IASB webcast on 25 July 2016, it was noted that, having considered:

- Whether the effect of non-linearity is material
- Whether the entity has a reasonable and supportable basis for this multiple scenario analysis
- Whether the application is possible without undue cost or effort

A conclusion may sometimes be reached that it is not necessary to actually use multiple scenarios to apply the impairment requirements in IFRS 9. However, multiple scenarios must always be considered.

At the December 2015 IFRS Transition Resource Group for Impairment of Financial Instruments meeting, the IFRS Transition Resource Group for Impairment of Financial Instruments also noted that consideration should be given to the consistency of forward-looking information used for the measurement of expected credit losses and for other purposes within the organisation, such as budgeting and forecasting. The IFRS Transition Resource Group for Impairment of Financial Instruments members acknowledged that there might be differences, but observed that these should be understood and explainable.

The IFRS Transition Resource Group for Impairment of Financial Instruments members also observed that the incorporation of forward-looking scenarios will require judgement. Consequently, they emphasised the importance of the IFRS 7 disclosure requirements relating to how forward-looking information has been incorporated into the determination of expected credit losses (see Chapter 50).¹⁶

5.6.2 Approaches to incorporate multiple economic scenarios

Since December 2015, banks have given significant attention to how multiple economic scenarios can be incorporated into expected credit loss calculations. We have seen three main approaches, as follows:

- (a) Probability-weighted scenarios - this is similar to the method discussed at the IFRS Transition Resource Group for Impairment of Financial Instruments meeting in December 2015 and illustrated in Illustration 5-5 in section 5.6.1 above. It involves establishing a number of scenarios (typically three scenarios but we have seen varying numbers, generally between two and four), estimating the losses that would arise in those scenarios and allocating a weighting to each scenario. Unlike Illustration 5-5 in section 5.6.1 above, these do not normally model economic variables such as unemployment rates in isolation - to do so, would also require complex modelling of the correlations between those variables. Instead, each scenario is normally a coherent combination of economic variables. For example, a scenario relevant to mortgage loans might include assumptions about unemployment, interest rates and house prices. This approach is transparent, but it may be difficult to assign the weightings to each scenario, requiring judgement as well as experience of the past. When selecting scenarios and respective weights, we expect banks to take into consideration the entire distribution of macroeconomic scenarios and select points (i.e., scenarios) from that distribution, with their respective weights representing the portion of the distribution represented by the scenario. We would also expect that the mean of the selected scenarios and weights is similar to that of the entire distribution.
- (b) The second approach is to calculate expected credit losses based on a central forward-looking scenario and to adjust the outcome where necessary by a factor to reflect the non-linearity of the loss distribution. In practice, it may be that a method similar to (a) above will need to be used in order to calculate this factor - so that it is not a very different approach. However, some banks view the merits of this approach as being less mechanistic and allowing more room for judgement.
- (c) Monte Carlo simulation - this method seeks to calculate the expected losses associated with the entire distribution of possible scenarios around the bank's central economic forecast. It has the advantage that it does not require the bank to formulate specific scenarios or assign weightings to them, but the simulation is dependent on assumptions that could not be transparent to either users or preparers, so that this solution can seem like a 'black box'. It is also very demanding as to the volume of data that has to be manipulated and it is not how most banks manage credit risk today. This method is quite rarely applied in practice.

How we see it

In practice, three main approaches have been used by banks to incorporate multiple economic scenarios into expected credit loss calculations, i.e., probability-weighted scenarios, central forward-looking scenario adjusted for non-linearity of the loss distribution and Monte Carlo simulation.

¹⁶ IASB Transition Resource Group for Impairment of Financial Instruments, [Meeting Summary](#), 11 December 2015, paras. 56. Available on the IFRS Foundation's website.

The effect of multiple scenarios will affect not just the probability of defaults but also the loss given defaults. For instance, for property-based lending it will be necessary to forecast the value of collateral associated with each economic scenario that is modelled. A consequence of this is that there may be a need to record an expected credit loss allowance for an asset that, based on the central forecast of future collateral values, is fully collateralised.

The use of multiple scenarios may also have an effect on the estimated EAD.

A number of other observations can be made about the use of multiple scenarios:

- Whichever approach is used to calculate the effect of non-linearity, it will be necessary for banks to communicate the result of the calculation in a manner which can be understood by readers of the financial statements. One possible approach would be for banks to report the losses associated with the central forecast and then, separately, the effect of the consideration of other scenarios. This would allow banks to communicate the amounts they expect to lose and would permit comparison between banks of the effect of the adjustment for non-linearity, even if the banks use different methods to make the calculation.
- It would seem that the effects of non-linearity depend on the countries in which banks operate and the economic characteristics of those countries. For instance, the effect of alternative scenarios of interest rates and unemployment may be greater in countries where there is more of a 'boom and bust' economic cycle. The size of the effect is also dependent on origination practices and the particular lending products - variable rate loans being more sensitive to interest rates than fixed-rate ones, while defaults on credit cards are more affected by unemployment rates. In some cases, the issue is seen as most relevant for exposures to a particular economic variable, an example being lending to companies involved in the oil industry. In this example, banks might model a number of scenarios as to how oil prices could evolve. A similar approach may be relevant for non-banks with similar exposures through long term construction contracts or leasing activities. There is also more likely to be non-linearity in the calculation of expected credit losses when exposures are collateralised by assets whose values also change in response to the economic conditions that drive the probability of default. An example is residential mortgage loans.
- It must be stressed that the IFRS Transition Resource Group for Impairment of Financial Instruments discussion highlighted the importance of calculating the effect of non-linearity using only reasonable and supportable information, implying that if the information is not available then there is a limit to what can be done. However, banks will also need to take into account their regulators' expectations (see section 1.5 above and section 7.1 below for Basel Committee guidance).

How we see it

The effect of non-linearity varies across the banks depending on the country of origin, economic conditions, and lending practices. It is important to disclose the effects of non-linearity in a manner that is readily understood by users of the financial statements.

The process of forecasting future economic conditions is discussed further in section 5.9.3 below.

5.6.3 Incorporating the impact of rare shock events

One of the main challenges in applying the IFRS expected credit loss model is to determine what is reasonable and supportable forward-looking information as per IFRS 9.5.5.17 and how to treat rare shock events with material, but uncertain, economic consequences. A major example of this is the coronavirus pandemic (which is addressed in more detail in section 7.8 below). On 27 March 2020, the IASB issued an education document in which it acknowledged that at the time it would likely be difficult to incorporate the specific effects of the coronavirus pandemic and government support measures on a reasonable and supportable basis.¹⁷ However, changes in economic conditions are reflected in macroeconomic scenarios applied by entities and in their weightings. When it is not possible to reflect such information in models, the IASB expects post-model overlays or adjustments to be considered.

¹⁷ [IFRS 9 and covid-19](#): Accounting for expected credit losses applying IFRS 9 Financial Instruments in the light of current uncertainty resulting from the covid-19 pandemic, IASB, 27 March 2020. Available on the IFRS Foundation's website.

Whether the impact of an event such as the coronavirus pandemic is reflected in an individual ECL assessment (estimating the probability of default on an individual basis), factored into the scenario analysis of future macroeconomic conditions on a collective basis, or adjusted through management overlays, depends on the entity's systems and processes and the facts and circumstances. In practice, entities are likely to consider a combination of these approaches. In estimating the impact of the event, entities must, however, be careful to avoid double-counting the effects of the various assumptions applied in individual assessments, macroeconomic scenarios and management overlays.

In abnormal circumstances such as those created by the coronavirus pandemic, it may take time before entities detect changes in risk indicators at a specific borrower level and are able to reassess the affected exposures. In order to accelerate the reflection of such changes in credit quality not yet detected at an individual borrower level, it may be appropriate to adjust ratings and the probability of defaults on a collective basis; considering risk characteristics such as the industry or geographical location of the borrowers (see section 6.5 below). However, many methods for performing collective assessments make use of historical information, which are not relevant in such circumstances.

One of the features of the coronavirus pandemic was that there were two sources of uncertainty: the development and easing of the pandemic itself and also the extent and the effect of the government response. In addition to updating gross domestic product and other macroeconomic variables in an entity's multiple economic scenarios, a challenge was to estimate how the impact of the coronavirus pandemic and any related government programmes affected specific sectors, regions and borrowers.

The IASB educational document noted that a number of assumptions and linkages underlying the way expected credit losses has been implemented to date may no longer hold in the environment affected by the pandemic. For example, the relationship between gross domestic product and other macroeconomic variables, such as unemployment and interest rates, and sector-specific variables, such as oil prices, is very likely to be different from what has been experienced in the past and reflected in economic forecasting models. The probability weightings assigned to macroeconomic scenarios may also need to be revisited. We observed during the pandemic, the following main reasons for making model adjustments and overlays:

- The challenges of making macroeconomic economic forecasts and assigning weightings to scenarios, due to uncertainties as to the possible spread of coronavirus, the risk of new variants, vaccine roll out and efficacy and the impact of government support, as well as the operational and timing challenges in incorporating the latest available macroeconomic inputs into the expected credit loss models.
- The lack of reliable data to model the impact on loans and the need to adjust to level of defaults estimated by expected credit loss models, given that they were never designed to address such extreme and rapid changes in macroeconomic variables and to reflect the level of government support provided to borrowers.
- Uncertainties around the timing and extent of defaults for some borrowers and vulnerable sectors in the longer term, as customer relief and government support measures come to an end.

A number of banks have provided additional quantitative and qualitative disclosures in respect of overlays and post-model adjustments, including the processes and governance in place. However, there is diversity in the granularity of the disclosures as well as the accompanying narrative and supporting analysis (see section 7.8.5 below).

Another example of rare shock events with material, but uncertain, economic consequences is war or conflict between countries. An entity with lending activities will need to consider its operations and exposures to entities, individuals and governments impacted by the war or conflict including loans and trade receivables, financial guarantees granted, bank deposits and debt securities. Furthermore, any sanctions imposed will need to be considered in the assessment of cash shortfalls for the purpose of measuring expected credit losses as any assets seized or restrictions imposed may adversely affect the cash or assets that would have been used to provide security or repay the financial asset of the entity. Rising prices of commodities such as oil, gas and wheat, potential slowdown in the global economy, rising inflation and interest rates would also need to be taken into account as a result of war events or conflicts.

There are potentially rare shock events related to climate change such as severe drought or flooding causing damage and disruption to individuals and businesses that needs to be taken into consideration (see section 7.9 below).

Entities impacted will need to model possible outcomes using multiple scenarios and to the extent that expected credit loss models were not designed or calibrated with these circumstances in mind, it may be necessary to make use of post-model adjustments or overlays.

How we see it

In estimating overlays, the widespread nature and severity of the consequences of a rare shock event such as the coronavirus pandemic, a war or conflict between countries, or climate change related rare shock events are not directly comparable with any recent similar events. It may be appropriate for this purpose, to plot several possible scenarios of what might happen over the forecasting period and assign weightings to them, to ensure that any overlay reflects the inherent uncertainty and non-linearity of potential outcomes.

5.7 Time value of money

An entity needs to consider the time value of money when measuring expected credit losses, by discounting the estimated losses to the reporting date using a rate that approximates the effective interest rate of the asset. [IFRS 9.5.5.17, IFRS 9.B5.5.44]. This has two components:

- Discounting recoveries to the date of default, hence 'a credit loss arises even if the entity expects to be paid in full but later than when contractually due'. [IFRS 9.B5.5.28].
- Discounting losses from the date of default to the reporting date. This is needed as the gross amortised cost of the asset is based on the contractual cash flows discounted at the effective interest rate, and therefore not discounting cash flows that are now not expected to be received would overstate the loss.

It is rare that customers just fail to pay amounts when due. In most cases, default also involves payments being paid late, while default can lead to the acceleration of payment of amounts that are not contractually due until a later date. Therefore, modelling losses involves modelling the timing of payments when default occurs and different patterns of timing of recoverable cash flows, such as the time it takes to foreclose on and sell collateral and complete bankruptcy proceedings, before the expected credit losses can be discounted back to the reporting date.

Of these two components, the first is typically included by banks in their calculation of the loss given default (although not necessarily using the effective interest rate). However, the second will also need to be calculated to comply with IFRS 9.

IFRS 9 and its Illustrative Examples are silent on how the calculation is made. In Illustrative Example 9 the present value of the observed loss is assumed and in Illustrative Example 8, a footnote states that, "Because the loss given default represents a percentage of the present value of the gross carrying amount, this example does not illustrate the time value of money".

One approach would be to model various scenarios as to how cash is collected once the loan has defaulted, and probability-weight the discounted cash flows of these various scenarios.

The discount rate is calculated as follows:

- For a fixed-rate financial asset, entities are required to determine or approximate the effective interest rate on the initial recognition of the financial asset, while for a floating-rate financial asset, entities are required to use the current effective interest rate. [IFRS 9.B5.5.44].
- For a purchased or originated credit-impaired financial asset (see section 3.3 above), entities are required to discount expected credit losses using the credit-adjusted effective interest rate determined on the initial recognition of the financial asset. [IFRS 9.B5.5.45].
- For a loan commitment (see section 11 below), entities are required to use the effective interest rate of the asset that will result once the commitment is drawn down. This would give rise to a consistent rate for a credit facility that includes both a loan (i.e., a financial asset) and an undrawn commitment (i.e., a loan commitment). If the effective interest rate of the resulting asset is not determinable, then entities are required to use the current risk-free rate (i.e., the discount rate that reflects the current market assessment of the time value of money). This is adjusted for risks specific to the cash flows, but only if the cash flows have not already been adjusted for these risks, in order to avoid double counting. [IFRS 9.B5.5.47, IFRS 9.B5.5.48].
- For financial guarantee contracts (see section 11 below), entities are required to use the current risk-free rate adjusted for risks specific to the cash flows, again to the extent that those cash flows have not already been adjusted for the risks. [IFRS 9.B5.5.48].
- For lease receivables (see section 10.2 below), entities are required to discount the expected credit losses using the same discount rate used in the measurement of the lease receivables in accordance with IFRS 16. [IFRS 9.B5.5.46].

Loss given default data available from Basel models include a discounting factor and sometimes this may be different from the rate required by IFRS 9. Furthermore, the discount rate used in Basel models only covers the period between default and subsequent recoveries. Therefore, entities will have to find ways to adjust their loss given defaults to reflect the discounting effect required by IFRS 9 (i.e., based on a rate that approximates the effective interest rate and over the entire period from recoveries back to the reporting date). Given the requirement to use an approximation to the effective interest rate, entities will need to work out how to determine a rate that is sufficiently accurate. One of the challenges is to interpret how much flexibility is afforded by the term 'approximation'.

Frequently asked questions

Question 5-3: What is meant by the current effective interest rate used to discount expected credit losses when an entity recognises interest revenue in each period based on the actual floating rate applicable to that period?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 11 December 2015 - Agenda paper no. 7)

At its meeting in December 2015 (see section 1.4 above), the IFRS Transition Resource Group for Impairment of Financial Instruments also discussed what was meant by the current effective interest rate when an entity recognises interest revenue in each period based on the actual floating-rate applicable to that period. The IFRS Transition Resource Group for Impairment of Financial Instruments first noted that the definition of the effective interest rate in IFRS 9 was carried forward essentially unchanged from the definition within IAS 39. Consequently, similarly to IAS 39, IFRS 9 does not specify whether an entity should use the current interest rate at the reporting date or the projected interest rates derived from the current yield curve as at the reporting date. There should be consistency between the rate used to recognise interest revenue, the rate used to project future cash flows (including cash shortfalls) and the rate used to discount those cash flows (as discussed above).

In relation to the guidance in IFRS 9.B5.5.47 and B5.5.48 on loan commitments when the effective interest rate on the resulting asset is not determinable and for financial guarantee contracts, we make the following observations:

- Although it is not clear in IFRS 9, any adjustment for the risks specific to the cash flows would be a reduction of the risk-free rate, not an increase. This would be consistent with the approach applied to provisions in IAS 37 *Provisions, Contingent Liabilities and Contingent Assets* and as was made clear in the staff paper presented to the Board when this treatment was discussed in December 2013.
- For loan commitments, when the effective interest rate on the resulting asset is not determinable, using the current risk-free rate adjusted for risks specific to the cash flows provides a prudent calculation of the expected credit losses, given that it is likely the entity which enters into the commitment will receive a credit spread on the loan if it is drawn down. It is in a much better position than the issuer of a financial guarantee contract, who will receive no credit spread if it is required to pay out on the guarantee.
- For financial guarantee contracts, the reduction in the risk-free discount rate will increase the present value of the obligation to pay claims to the guarantee holder. This reflects the additional compensation that would be demanded to take on this risky obligation, in particular to bear the risk that claims payments will be higher than the probability-weighted expected amount.

How we see it

For financial guarantee contracts, IFRS 9 requires that the risk-free discount rate is adjusted only if the cash flows have not already been adjusted for the associated risks. However, given that the cash flows should have already been estimated with regard to any non-linearities in the distribution of losses, the cash flows will have already been adjusted, at least partially, for risk. Hence any further adjustment will need to reflect only those risks not already captured.

5.8 Losses expected in the event of default

This section discusses the measurement of expected credit losses taking into account credit enhancements such as collateral and financial guarantees, cash flows from the sale of a defaulted loan and collection costs paid to an external debt collection agency.

5.8.1 Credit enhancements: collateral and financial guarantees

Although credit enhancements such as collateral and guarantees play only a limited role in assessing whether there has been a significant increase in credit risk (see section 6.1 below), they do affect the measurement of expected credit losses. For example, for a mortgage loan, even if an entity determines that there has been a significant increase in credit risk on the loan since initial recognition, if the expected proceeds from the collateral (i.e., the mortgaged property) exceeds the amount lent, then the entity may have very low or nil expected credit losses, and hence an allowance of close to zero.

Paragraph B5.5.55 of IFRS 9 sets out the requirements for measuring expected credit losses:

[IFRS 9.B5.5.55].

Extract from IFRS 9

Collateral

B5.5.55 For the purposes of measuring expected credit losses, the estimate of expected cash shortfalls shall reflect the cash flows expected from collateral and other credit enhancements that are part of the contractual terms and are not recognised separately by the entity. The estimate of expected cash shortfalls on a collateralised financial instrument reflects the amount and timing of cash flows that are expected from foreclosure on the collateral less the costs of obtaining and selling the collateral, irrespective of whether foreclosure is probable (ie the estimate of expected cash flows considers the probability of a foreclosure and the cash flows that would result from it). Consequently, any cash flows that are expected from the realisation of the collateral beyond the contractual maturity of the contract should be included in this analysis. Any collateral obtained as a result of foreclosure is not recognised as an asset that is separate from the collateralised financial instrument unless it meets the relevant recognition criteria for an asset in this or other Standards.

The wording in IFRS 9.B5.5.55 does not mean that the entity is required to assume that recovery will be through foreclosure only, but rather that the entity calculates the cash flows arising from the various ways that the asset may be recovered, only some of which may involve foreclosure, and to probability-weight these different scenarios (see Illustration 5-1 in section 5.4 above).

Although IFRS 9 does not refer to fair value when determining the valuation of the collateral, in practice, an entity is likely to estimate the cash flows from the realisation of the collateral, based on the fair value of the collateral. In the case of illiquid collateral, such as real estate, adjustments will probably need to be made for expected changes in the fair value, depending on the economic conditions at the estimated date of selling the collateral. Also, as described in sections 5.6.1 and 5.6.2 above, the entity considers multiple scenarios in ascribing value to collateral.

Also, any collateral obtained as a result of foreclosure is not recognised as an asset that is separate from the collateralised financial instrument unless it meets the relevant recognition criteria for an asset in IFRS 9 or other standards. [IFRS 9.B5.5.55].

If a loan is guaranteed by a third-party as part of its contractual terms, it carries an allowance for expected credit losses based on the combined credit risk of the guarantor and the guaranteed party, by reflecting the effect of the guarantee in the measurement of losses expected on default.

5.8.1.A Guarantees that are part of the contractual terms

As already mentioned, IFRS 9.B5.5.55 states that “For the purposes of measuring expected credit losses, the estimate of expected cash shortfalls shall reflect the cash flows expected from collateral and other credit enhancements that are part of the contractual terms and are not recognised separately by the entity...”.

Frequently asked questions

Question 5-4: What is meant by 'part of the contractual terms'?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 11 December 2015 - Agenda paper no. 5)

A challenge is interpreting what constitutes 'part of the contractual terms'. This was addressed by the IFRS Transition Resource Group for Impairment of Financial Instruments at its meeting in December 2015 (see section 1.4 above), specifically whether the credit enhancement must be an explicit term of the related asset's contract in order for it to be taken into account in the measurement of expected credit losses, or whether other credit enhancements that are not recognised separately can also be taken into account.

The IFRS Transition Resource Group for Impairment of Financial Instruments noted that:

- The definition of credit losses states that "...The cash flows that are considered shall include cash flows from the sale of collateral held or other credit enhancements that are integral to the contractual terms...". [IFRS 9 Appendix A]. Consequently, credit enhancements included in the measurement of expected credit losses should not be limited to those that are explicitly part of the contractual terms.
- An entity must apply its judgement in assessing what is meant by 'integral to the contractual terms' and in making that assessment, an entity should consider all relevant facts and circumstances.
- IFRS 7 requires disclosures to enable users of financial statements to understand the effect of collateral and other credit enhancements on the amounts arising from expected credit losses (see section 15 below and Chapter 50).

Although not reflected in the official minutes of the IFRS Transition Resource Group for Impairment of Financial Instruments meeting, the IASB members highlighted during the course of the discussion that there was no intention to alter the treatment when drafting IFRS 9. In practice, previously under IAS 39, most banks incorporated guarantees as part of their measurement of losses given default.

The IFRS Transition Resource Group for Impairment of Financial Instruments also emphasised that IFRS 9.B5.5.55 was drafted only with the intention to caution against double counting those credit enhancements that are already recognised separately, and was not intended to limit the inclusion of credit enhancements that were previously included in IAS 39 allowances for loan-losses.

Question 5-5: Whether the cash flows expected from a financial guarantee contract or any other credit enhancement can be included in the measurement of expected credit losses if the credit enhancement is required to be recognised separately applying IFRS standards?

(IFRS Interpretations Committee meeting 27 November 2018 and 5 March 2019 - Agenda paper no. 6 and no. 12 respectively)

In November 2018 and March 2019, the IFRS IC referred to IFRS 9.B5.5.55 and observed that the cash flows expected from a credit enhancement are included in the measurement of expected credit losses only if the credit enhancement is both:

- Part of the contractual terms
- Not recognised separately by the entity

Similar to the IFRS Transition Resource Group for Impairment of Financial Instruments, the IFRS IC concluded that, if a credit enhancement is required to be recognised separately by IFRS accounting standards (an example would be a credit default swap that would need to be measured at fair value through profit or loss), an entity cannot include the cash flows expected from it in the measurement of expected credit losses. An entity applies the applicable IFRS accounting standard to determine whether it is required to recognise a credit enhancement separately. Paragraph B5.5.55 of IFRS 9 does not provide an exemption from applying the separate recognition requirements in IFRS 9 or other IFRS accounting standards.

However, the IFRS Transition Resource Group for Impairment of Financial Instruments discussion does not answer the question of how to interpret when a financial guarantee is 'integral to the contractual terms' when it is not mentioned in the contractual terms of the loan.

It seems reasonably clear that a credit default swap on a loan entered into by the lender to mitigate its credit risk on the loan, would not normally be classed as integral to a loan's contractual terms. The second criterion mentioned in IFRS 9.B5.5.55 is that the credit enhancement is not recognised separately and separate accounting for a derivative is clearly required by IFRS 9. Also, payment under a credit default swap does not normally require the holder of the instrument to have suffered the credit loss referenced by the swap. As a result, cash flows from a credit default swap that is accounted for as a derivative would not be included in the measurement of expected credit losses of the associated loan.

For a financial guarantee (as defined in IFRS 9), one view is that it is integral to the contractual terms of a loan only if it is, at least implicitly, part of the contractual terms of the loan. Examples of an implicit contractual linkage might include:

- **Inseparability:** The financial guarantee is inseparable from the loan contract, i.e., the loan cannot be transferred without the guarantee.
- **Local laws and regulations:** Credit enhancements required by local laws and regulations that govern the loan contract but that are not specifically in the contract itself. For example, in some jurisdictions, legislation requires that lenders must take out financial guarantee contracts that contain little or no down payment in respect of certain loans.
- **Business purpose:** The guarantee and the loan have been contracted in contemplation of one another, i.e., the loan would not have been contracted without the guarantee.
- **Market convention:** The exposure and the financial guarantee are traded as a package in the market.

In response to the coronavirus pandemic, the European Securities and Market Authority issued a public statement on 25 March 2020, which referenced the IFRS Transition Resource Group for Impairment of Financial Instruments' meeting and observation in December 2015 that credit enhancements included in the measurement of expected credit losses should not be limited to those that are explicitly part of the contractual terms. The European Securities and Market Authority noted that this is the case, in particular, when the public guarantee is provided in conjunction with broadly applicable *ex-lege* debt moratoria or economic support and relief measures. The European Securities and Market Authority was of the view that the assessment of whether the public guarantee can be considered an integral part of the contractual terms or not, may involve judgement. The European Securities and Market Authority highlighted the importance that such judgements, to the extent significant, be clearly disclosed in the entity's financial statements.¹⁸

Another view might be that any contract that meets the definition of a financial guarantee under IFRS 9 can be considered 'integral to the contractual terms' of the guaranteed loan, when the guarantee is entered into at the same time as, or within a short time after, the loan is advanced. Alternatively, if an entity enters into a guarantee for a pre-existing loan, it would generally not be considered integral to that loan if it was not anticipated when the loan was originally granted. Whether a credit enhancement is integral depends on an assessment of the individual facts and circumstances and is likely to require judgement. The timing of entering into the loan and financial guarantee provides an indication but is not in all cases determinative on its own that the 'integral' criterion is met. This is consistent with the report issued by the European Securities and Market Authority on 17 May 2022 which noted that "the mere fact that the debt instrument (portfolio loans) is entered into at the same time as the debenture, which is a result of the business model and risk management strategy of the issuer, is not sufficient to conclude that credit enhancement is integral to the portfolio loan agreements".¹⁹

As the definition of a financial guarantee contract requires the loan to be specified in the contractual terms of the financial guarantee and it is necessary for the lender to incur a credit loss on the loan to be reimbursed, there is a clear contractual linkage that ensures that any credit loss incurred on the loan will be compensated by the financial guarantee and no compensation will arise on the financial guarantee unless a credit loss is actually incurred by the lender on the guaranteed loan.

Further, when the IASB considered and rejected an 'insurance approach' for credit default swaps as part of its hedge accounting deliberations, it was noted that doing so would be similar to the treatment of a collateral or a guarantee and so "would have a simple interaction with an impairment model" as it "would affect the estimate of the recoverable cash flows". Thus, at least at this stage of the development of IFRS 9, the Board appear to have regarded all guarantees (as opposed to credit default swaps) as capable of being treated as credit enhancements for the expected credit loss model [IFRS 9.BC6.531, IFRS 9.BC6.534].

Most guarantees require payment of a premium. To the extent that the guarantee is considered integral to the loan, it would be consistent with this notion to treat the cost of the guarantee as a transaction cost of making the loan. This means that the lender would add this cost to the initial carrying amount of the loan and so reduce the future effective interest rate. It does not make a difference to the accounting for the loan whether the guarantee premium is paid upfront or in instalments over the life of the loan. If the premium is payable in instalments, it follows (at least, in theory, although the effect is unlikely to be material) that the full cost of the guarantee needs to be included in setting the loan's effective interest rate.

5.8.1.B Guarantees that are not part of the contractual terms

Although it is not always clear as to when a financial guarantee contract would be regarded as part of the contractual terms as per IFRS 9.B5.5.55, this does not affect the profit or loss recognition by the lender if an asset can be recognised in respect of the guarantee. Such an outcome may be achieved by following either of the two approaches described below.

A financial guarantee contract is likely to satisfy the definition of an insurance contract in IFRS 17 *Insurance Contracts* but for the holder it will be excluded from the scope of IFRS 17 because it is a direct insurance contract held by a policyholder (as opposed to a policyholder of a reinsurance contract). [IFRS 17.7(g)]. It is therefore outside the scope of IFRS 9. [IFRS 9.2.1(e)]. IAS 8 *Accounting Policies, Changes in Accounting Estimates and Errors* addresses situations where no IFRS specifically applies to a transaction, i.e., the holder of a financial guarantee contract will normally need to develop its accounting policy in accordance with the hierarchy in IAS 8. [IAS 8.10, IAS 8.11].

Applying the IAS 8 hierarchy, one possibility would be to look to IAS 37 and treat the guarantee as a right to a reimbursement in respect of the impairment loss. IAS 37 permits a reimbursement of a liability to be recognised as an asset, not exceeding the amount of the provision, when it is virtually certain that the reimbursement will be received if the obligation for which a provision has been established is settled. [IAS 37.53]. In this instance, the benefit of the guarantee would be recognised as an asset to the extent it is virtually certain a recovery could be made if the lender were to suffer the impairment loss on the loan. One of the key advantages of a financial guarantee contract, compared to a normal insurance contract, is that they are typically drawn up using standard terms and conditions and there is often little doubt that an obligation would arise for the guarantor if the reference asset were to default. However, care needs to be taken to establish, based on the contractual terms of the arrangement, that a right to a recovery would, indeed, be virtually certain.

To record a reimbursement asset under IAS 37, it is less clear whether the credit risk of the guarantor needs to be assessed in determining whether recovery would be virtually certain, or whether the guarantor's credit risk would only be reflected in measuring the reimbursement asset. One view is that the guarantor would either have to present a very low credit risk or else the guarantee would itself need to be collateralised in order to conclude that a reimbursement right can be recognised. In this case, care is also be taken to ensure that there is no correlation between the credit risk of the loan and that of the guarantor, as would be the case if the guarantor's financial strength were to reduce at the same time that the loan is likely to default. Applying this view, if a reimbursement is considered virtually certain, there would probably be no need also to reflect the guarantor's credit risk in the measurement of the asset. In contrast, the second view imposes a less stringent criterion for recognising an asset, but would reduce the recognised asset to reflect the probability that the guarantor may be unable to meet its obligation (perhaps by applying an expected credit loss deduction, by analogy to IFRS 9).

An alternative approach for recording an asset in respect of the guarantee would be to look to IFRS 3 *Business Combinations* and draw an analogy with indemnification assets. First, IFRS 3 requires all contingent liabilities to be recognised on a business combination, whether or not they are probable, which is closer to the IFRS 9 notion of an expected credit loss than the contingent liability recognition threshold under IAS 37. Second, IFRS 3 allows an indemnification asset to be recognised, measured on the same basis as the indemnified asset or liability, subject to any contractual limitations on its amount. Also, for an indemnification asset that is not subsequently measured at its fair value, the measurement is subject to management's assessment of the collectability of the indemnification asset. [IFRS 3.57]. Adopting this indemnification asset approach, the credit risk of the guarantor becomes a measurement, rather than a recognition issue. It would not be necessary to assess if the credit risk of the guarantor is very low, since credit risk is instead reflected in the measurement of the guarantee.

How we see it

Whether an analogy is made to a reimbursement right under IAS 37 or an indemnification asset under IFRS 3, an asset may be recognised in respect of an acquired financial guarantee contract in the statement of financial position, not exceeding the amount of the expected credit loss allowance on the guaranteed asset, and may result in an offsetting entry against expected credit loss in profit or loss, depending on the accounting policy of the lender. Except for the possible treatment of the guarantor's credit risk, using either of these approaches the overall effect on profit or loss for the lender may be often the same as if the guarantee was included in the measurement of the expected credit loss of the guaranteed asset. The right would, however, be presented as an asset rather than as a reduction of the impairment allowance.

Whereas it is relatively straightforward as to how to account for premiums paid for guarantees that are considered integral to a loan (as discussed in the previous section), it is less clear when the guarantee is not considered integral. If the entity who makes a loan and, at the same time, pays for a guarantee, records both the unamortised cost of the guarantee plus also a reimbursement or indemnification asset equivalent to the 12-month expected credit losses, the total amount at which the guarantee is initially recorded in the financial statements will exceed its fair value. This is because the cost of the guarantee will already include the guarantor's expectations of future losses. One view is to consider this to be 'double counting' and so, to restrict the reimbursement/indemnification right to the excess (if any) of the expected credit loss over the cost of the guarantee that is already reflected in the balance sheet.

There is another view that recognising both the unamortised cost of the guarantee and a reimbursement right/indemnification asset equal to the expected credit loss is necessary to be consistent with the accounting for the loan. Another way of expressing this is to say that it is appropriate for the guarantee to be recorded at more than its initial fair value as the guaranteed loan is recorded initially at less than its fair value by a similar amount, i.e., the expected credit loss. The subsequent amortisation of the cost of the guarantee would be balanced by the recognition of the credit spread in the interest earned on the loan.

ECL losses booked prior to a non-integral financial guarantee being entered into reflect the expected losses at that point. If a financial guarantee is entered into subsequently, it provides credit protection going forward and would not in itself cause the reversal of previously recognised ECL. Although it may provide a right to receive specified payments to reimburse the lender for losses it incurs should the borrower fail to make payments due, it cannot reverse or undo losses that were previously incurred in line with the IFRS 9 impairment requirements. This can be explained by the fact that the fair value of the expected credit losses recognised to date would be reflected in the premium payable by Entity A for the guarantee and therefore it would be inappropriate to reverse previously recognized credit losses and then transfer them to a later period as the guarantee premium is amortised through the income statement.

When considering the statement of financial position, under this approach the financial guarantee asset is essentially a combination of the reimbursement asset, and the unamortized premium paid. This approach mirrors the accounting by an issuer of a financial guarantee where the issuer recognises the guarantee at the higher of the ECL allowance, and unamortized premium [IFRS 9.4.2.1(c)]. Consequently, for the holder of the guarantee, on initial recognition the total financial guarantee asset recognised is the higher of the ECL allowance, and the unamortized premium.

The following illustrates the issue.

Illustration 5-6: Non-integral financial guarantee

On 1/1/20X1 Entity A grants a loan to Entity X of CU100. By the end of the reporting period at 31/12/20X1 there has been an increase in credit risk and an ECL allowance of CU1 was recognised. On 1/1/20X2 Entity A enters into a financial guarantee contract (FGC), which is not integral to the underlying asset, with Bank B, to guarantee the loan granted to Entity X and pays a premium upfront of CU4. As discussed above this can be looked at as representing a payment for the unamortised cost of the guarantee of CU3 and a reimbursement asset representing the ECL of CU1. It is judged virtually certain that the guaranteed amount will be received in the event of a claim, and that Bank B has a low credit risk.

From the perspective of Entity A, when the non-integral FGC is entered into for an existing underlying asset, ECL losses incurred prior to entering into the guarantee cannot be reversed, i.e., in the fact pattern above, on 1/1/20X2, Entity A cannot reverse out the ECL loss of CU1 that was incurred prior to entering into the guarantee.

How we see it

Irrespective of how the guarantee and reimbursement right/indemnification asset are measured, if the lender acquires the guarantee subsequent to making the loan and the loan has, in the meantime, increased in credit risk, it is likely that the lender will pay more for the guarantee, to reflect this increase in credit risk. If so, this additional amount will crystallise a loss for the lender and so is not recorded as a reimbursement/indemnification right and a reversal of a previously recognised impairment loss. When a non-integral guarantee is entered into for an existing underlying asset, any ECL losses incurred before the guarantee is entered into are not reversed.

5.8.1.C Government relief measures

Entities will need to consider any form of support provided by a government and this is dependent on whether its effect is to prevent a default by the borrower, or to compensate a lender for losses it suffers due to the borrower's default. In some cases, a government may provide direct financial support to a borrower. For example, the government may offer to compensate employees who have lost their job with a portion of their previous salary for a period of time. These forms of financial support prevent or reduce the extent to which a borrower would otherwise default on a loan. These forms of financial support are considered in a lender's assessment of significant increase in credit risk and the probability of default as it reduces the credit risk associated with the underlying loan.

In other cases, a guarantee may be issued to a lender to compensate it for losses it suffers due to default by a borrower. Such a guarantee does not prevent default by a borrower, but rather reduces the effect of any default. The accounting effect of such a guarantee depends on whether it is integral to the contractual terms of the guaranteed loan and whether it is required to be recognised separately by the lender.

If a guarantee is integral to the loan and is not required to be recognised separately by the lender, the guarantee is taken into account in calculating the loss given default of the guaranteed loan (see section 5.8.1.A above), however, it does not affect the significant increase in credit risk assessment. The coronavirus pandemic is an example of when the impact on the value of the enhancement (e.g., shares or bond prices, real-estate values and the credit standing of any guarantor) also needs to be considered.

If a guarantee is not considered to be integral, it may still meet the criteria to be recognised as a reimbursement asset by analogy to IAS 37. Where this applies, it would have to be recognised separately in the statement of financial position and may result in an offsetting entry against expected credit loss in profit or loss, depending on the accounting policy of the lender (see section 5.8.1.B above).

Where guarantees are issued by governments for a below-market rate fee, both borrowers and lenders will have to assess whether this constitutes a government grant to be accounted for and disclosed in accordance with IAS 20 *Accounting for Government Grants and Disclosure of Government Assistance*. In performing such an assessment, entities will need to consider the level of the interest rate offered to the borrower on the guaranteed loan and whether the economics of the overall transaction provide a benefit to the lender, the borrower or to both. For example, if a benefit to a lender from a below-market rate fee on a guarantee is required to be partially offset by a reduction in the interest earned on the loan to the borrower, the value of any government grant to the lender may be reduced or eliminated. In such a case, the value of the grant accrues mainly to the borrower in the form of a below-market rate loan relative to the borrower's credit risk.

Parent or other group entities will be required to calculate expected credit losses in their separate financial statements in respect of guarantees they provide against the debts of other group companies.

5.8.2 Cash flows from the sale of a defaulted loan

Frequently asked questions

Question 5-6: Whether cash flows that are expected to be recovered in certain circumstances where an entity chooses to sell a defaulted loan to a third-party in order to maximise recovery cash flows could be included in the measurement of expected credit losses?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 11 December 2015 - Agenda paper no. 6)

At its meeting in December 2015 (see section 1.4 above), the IFRS Transition Resource Group for Impairment of Financial Instruments discussed whether cash flows that are expected to be recovered from the sale on default of a loan could be included in the measurement of expected credit losses. The IFRS Transition Resource Group for Impairment of Financial Instruments members noted that:

- Such cash flows should be included in the measurement of expected credit losses if:
 - (a) Selling the loan is one of the recovery methods that the entity expects to pursue in a default scenario.
 - (b) The entity is neither legally nor practically prevented from realising the loan using that recovery method.
 - (c) the entity has reasonable and supportable information upon which to base its expectations and assumptions.
- In order to support an entity's expectation that loan sales would be used as a recovery method in a default scenario, an entity's past practice would be an important consideration. However, future expectations, which may differ from past practice, would also need to be considered. With respect to the amount of recovery proceeds to be included in the measurement of expected credit losses, an entity should consider relevant market related information relating to loan sale prices.
- In these circumstances, the inclusion of recovery sale proceeds in the measurement of expected credit losses would be appropriate for financial instruments in all stages; stage 1, 2 and 3 (see section 3.1 above). This is because when measuring expected credit losses, IFRS 9 requires an entity to consider possible default scenarios for financial instruments in all three stages.
- Given that it is necessary to consider multiple scenarios in measuring expected credit losses (see section 5.6.1 above), it is possible that an entity will need to calculate the cash flows based on both a scenario in which the loan will be sold and one in which it will not. Expected sale proceeds would only be relevant when considering the possibility that a credit loss occurs (i.e., in a default scenario) and would not be relevant when considering the possibility that no credit loss occurs (i.e., in a performing scenario). For example, if, in the case of a particular loan, an entity concluded that there was a 10% probability of default occurring, it would only be when considering the outcome of this default scenario that expected sale proceeds would be considered. If, in that default scenario, the entity expected to recover 30% of the contractual cash flows of the loan through sale proceeds but only 25% through continuing to hold, then the loss given default would be 70% rather than 75%. In addition, the expected sale proceeds should be net of selling costs.

5.8.3 Treatment of collection costs paid to an external debt collection agency

Questions have arisen on how the collection costs paid to an external debt collection agency affect the measurement of expected credit losses. As an example, a bank engages the services of an external debt collection agency to recover accounts that are 90 days past due on its behalf and, in exchange, pays the agency a fee based on the amount recovered.

One view could be that in measuring the expected credit losses, all cash flows related to the recovery of the asset are considered in estimating the expected cash shortfalls. Therefore, the recoveries and any incremental and directly attributable payments made to the external agency are both considered, irrespective of whether the collections costs are deducted from the amount recovered or paid to the external debt collection agency separately. This view is based on the fact that IFRS 9 specifies that the estimate of cash flows from the realisation of collateral include the costs of obtaining the collateral. This can be read to suggest that all cash flows relating to the various ways of recovering the asset are considered in measuring the expected shortfall. An analogy can also be made with the IFRS Transition Resource Group for Impairment of Financial Instruments discussion on sales of assets where selling costs are to be included (see section 5.8.2 above). This also reflects that if the cash flows expected to be received are greater than those that would be realised if the agency were not used, excluding the collection cost paid to the agency will understate the expected credit losses. Further, for assets that are purchased credit-impaired, these costs may already be implicit in the fair value at which they are acquired and so, unless these costs are included, the effective interest rate would be inflated.

Another view could be that only cash flows related to the contractual terms of the financial instrument are considered, apart from the costs of obtaining and selling collateral. This would exclude costs of an external debt collection agency. This view is based on the definition of a credit loss as “the difference between all contractual cash flows that are due to an entity in accordance with the contracts and all the cash flows that the entity expects to receive (i.e., net of all cash shortfalls). The cash flows that are considered shall include cash flows from the sale of collateral held or other credit enhancements that are integral to the contractual terms” [IFRS 9 Appendix A]. Since the collection costs paid to the agency are not part of the contractual terms of the financial instrument, nor a cost for realising collateral, then they are not considered in the calculation of expected credit losses. The reason for treating costs of realising collateral differently is that the proceeds from selling collateral is itself not a contractual cash flow of the instrument and the commercial value of the collateral would include provision for such costs. The analogy with sales of assets is considered irrelevant for the same reasons as they do not relate to the recovery of contractual cash flows.

Entities may take into account incremental collection costs incurred internally when measuring expected credit losses although this has not yet been seen widely in practice. An example of incremental internal collection costs would be incentives for employees to achieve certain collection targets. However, if the internal collection costs are not incremental, they cannot be included in the measurement of expected credit losses.

How we see it

The recoveries from a defaulted loan and any incremental and directly attributable payments made to an external agency can be included in the measurement of expected credit losses. This is the case irrespective of whether the collections costs are deducted from the amount recovered or paid to the external debt collection agency separately. Similarly, incremental collection costs incurred internally can be included in the measurement of expected credit losses, although it is unusual for such costs to be incremental and this has not yet been seen widely in practice.

5.9 Reasonable and supportable information

IFRS 9 requires an entity to consider reasonable and supportable information that is available without undue cost or effort at the reporting date about past events, current conditions and forecasts of future economic conditions and that is relevant to the estimate of expected credit losses, including the effect of expected prepayments. [IFRS 9.5.5.17(c), IFRS 9.B5.5.51].

5.9.1 Undue cost or effort

Extract from IFRS 9

B5.5.49 For the purpose of this Standard, reasonable and supportable information is that which is reasonably available at the reporting date without undue cost or effort, including information about past events, current conditions and forecasts of future economic conditions. Information that is available for financial reporting purposes is considered to be available without undue cost or effort.

[IFRS 9.B5.5.49].

The term undue cost or effort is not defined in IFRS 9, although it is clear from the guidance that information available for financial reporting purposes is considered to be available without undue cost or effort.

Beyond that, although IFRS 9 explains that entities are not required to undertake an exhaustive search for information, it does include, as examples of relevant information, data from risk management systems, as described in section 5.9.2 below.

What is available without undue cost or effort would be an area subject to management judgement in assessing the costs and associated benefits. This is consistent with the guidance in International Financial Reporting Standard for Small and Medium-sized Entities (IFRS for SMEs) in relation to the application of undue cost or effort:

Extract from IFRS for SMEs

- 2.14B Considering whether obtaining or determining the information necessary to comply with a requirement would involve undue cost or effort depends on the entity's specific circumstances and on management's judgement of the costs and benefits from applying that requirement. This judgement requires consideration of how the economic decisions of those that are expected to use the financial statements could be affected by not having that information. Applying a requirement would involve undue cost or effort by an SME if the incremental cost (for example, valuers' fees) or additional effort (for example, endeavours by employees) substantially exceed the benefits that those that are expected to use the SME's financial statements would receive from having the information. An assessment of undue cost or effort by an SME in accordance with this Standard would usually constitute a lower hurdle than an assessment of undue cost or effort by a publicly accountable entity because SMEs are not accountable to public stakeholders.
- BC232 The IASB also thinks that the clarifying guidance will help to emphasise two further points:
- (a) that the undue cost or effort exemption is not intended to be a low hurdle. This is because an entity is required to carefully weigh the expected effects of applying the exemption on the users of the financial statements against the cost or effort of complying with the related requirement. In particular, the IASB observed that it would expect that if an entity already had, or could easily and inexpensively acquire, the information necessary to comply with a requirement, any related undue cost or effort exemption would not be applicable. This is because, in that case, the benefits to the users of the financial statements of having the information would be expected to exceed any further cost or effort by the entity.
 - (b) that an entity must make a new assessment of whether a requirement will involve undue cost or effort at each reporting date.

If the reporting entity is a bank, there would presumably be a higher hurdle to determine what credit risk information would require undue cost or effort, compared to a reporter that is not a bank, given that the benefit to users of its financial statements would be also expected to be higher. It is also an issue on which the Basel Committee has issued guidance (see section 7.1 below).

5.9.2 Sources of information

IFRS 9 provides some guidance on the information to consider when measuring expected credit losses: [IFRS 9.B5.5.51]

Extract from IFRS 9

- B5.5.51 An entity need not undertake an exhaustive search for information but shall consider all reasonable and supportable information that is available without undue cost or effort and that is relevant to the estimate of expected credit losses, including the effect of expected prepayments. The information used shall include factors that are specific to the borrower, general economic conditions and an assessment of both the current as well as the forecast direction of conditions at the reporting date. An entity may use various sources of data, that may be both internal (entity-specific) and external. Possible data sources include internal historical credit loss experience, internal ratings, credit loss experience of other entities and external ratings, reports and statistics. Entities that have no, or insufficient, sources of entity-specific data may use peer group experience for the comparable financial instrument (or groups of financial instruments).

Although the expected credit losses reflect an entity's own expectations of credit losses, an entity also considers observable market information about the credit risk of particular financial instruments. [IFRS 9.B5.5.54]. Therefore, although entities with in-house economic teams will inevitably want to use their internal economic forecasts, while loss estimation models will be built based on historical data, they must not ignore external market data.

5.9.3 Information about past events, current conditions and forecasts of future economic conditions

Entities are not only required to use historical information (e.g., their credit loss experience) that is adjusted to reflect the effects of current conditions, but they are also required to consider how forecasts of future conditions would affect their historical data. A discussion of how this process needs to consider the existence of non-linearity in how expected losses will change with varying economic conditions and the need to assess multiple economic scenarios is included in section 5.6.1 above. This section explores some of the other challenges in forecasting future conditions and the consequent expected credit losses.

The degree of judgement that is required to estimate expected credit losses depends on the availability of detailed information. An entity is not required to incorporate detailed forecasts of future conditions over the entire expected life of a financial instrument. IFRS 9 notes that as the forecast horizon increases, the availability of detailed information decreases and the degree of judgement required to estimate expected credit losses increases. Therefore, an entity is not required to perform a detailed estimate for periods that are far in the future and may extrapolate projections from available, more detailed information.

[IFRS 9.B5.5.50]. Most banks apply a 3 to 5 year period over which macro-economic variables are considered to be capable of being forecast.

Beyond the horizon to which economic conditions can be reliably forecast, the application guidance suggests that entities may often be able to assume that economic conditions revert to their long-term average. There are at least two methods of how this might be done: either by reverting to the average immediately beyond the forecast horizon, or by adjusting the forecast data to the long-term average over a few years. The latter would, perhaps, more effectively make use of all reasonable and supportable information.

Historical information is used as a starting point from which adjustments are made to estimate expected credit losses on the basis of reasonable and supportable information that incorporates both current and forward-looking information: [IFRS 9.B5.5.52]

- In most cases, adjustments would be needed to incorporate those effects that were not present in the past or to remove those effects that are not relevant for the future.
- In some cases, unadjusted historical information may be the best estimate, depending on the nature of the historical information and when it was calculated, compared to circumstances at the reporting date and the characteristics of the financial instrument being considered. But it is not assumed to be appropriate in all circumstances. [IFRS 9.BC5.281].

Additionally, when considering whether historical credit losses are adjusted, an entity needs to consider various items, including:

- Whether the historical data captures expected credit losses that are through-the-cycle (i.e., estimates based on historical credit loss events and experience over the entire economic cycle) or point-in-time (i.e., estimates based on information, circumstances and events at the reporting date).
- The period of time over which its historical data has been captured and the corresponding economic conditions represented in that history. The historical data period may reflect unusually benign or harsh conditions unless it is long enough. Meanwhile, products, customers and lending behaviours all change over time. When using historical credit loss experience, it is important that information about historical credit losses is applied to groups that are defined in a manner that is consistent with the groups for which the historical credit losses were observed.

The estimates of changes in expected credit losses are directionally consistent with changes in related observable data from period to period (i.e., consistent with trends observed on payment status and macroeconomic data such as changes in unemployment rates, property prices, and commodity prices). Also, in order to reduce the differences between an entity's estimates and actual credit loss experience, the estimates of expected credit losses ought to be back-tested and re-calibrated, i.e., an entity regularly reviews its inputs, assumptions, methodology and estimation techniques used as well as its groupings of sub-portfolios with shared credit risk characteristics (see section 6.5 below).

Back-testing will be considerably more challenging for forecasts over several years than may be the case for just the 12-month risk of default, because detailed information is not available over the forecast horizon and the degree of judgement increases as the forecast horizon increases. [IFRS 9.B5.5.52, IFRS 9.B5.5.53]. Also, economic forecasts are usually wrong, as reality is much more complex than can ever be effectively modelled. Therefore, it is probably not a useful exercise to back-test macroeconomic assumptions against what actually transpires, but it is useful to back-test whether, for a given macroeconomic scenario, credit losses increased or decreased as expected.

In estimating expected credit losses, entities must consider how to bridge the gap between historical loss experience and current expectations. Estimating future economic conditions is only the first step of the exercise. Having decided what will happen to macroeconomic factors such as interest rates, house prices, unemployment and gross domestic product growth, entities then need to decide how they translate into expected credit losses. This will need to reflect how such changes in factors affected defaults in the past. However, it is possible that the forecast combination of factors may have never been seen historically together.

For many banks, Basel probability of defaults are used as a starting point but there is a need for a different calibration for IFRS 9, in order to transform a Basel probability of default into an unbiased point in time metric and include forward-looking expectations. Stress testing resources, previously working almost exclusively with capital issues, also play a role in calculating lifetime expected credit losses, although the scenarios modelled for IFRS 9 will not necessarily be stressed. However, estimating losses (especially given the need to consider multiple scenarios) will still be challenging for many entities.

5.9.4 Events and new information obtained after expected credit losses have been calculated

Frequently asked questions

Question 5-7: Whether and how to incorporate events and forecasts, when applying the impairment requirements at the reporting date, that occur:

- (a) After economic forecasts have been made but before the reporting date
- (b) Between the reporting period end and the date of signing the financial statements

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 22 April 2015 - Agenda paper no. 2)

In April 2015, the IFRS Transition Resource Group for Impairment of Financial Instruments (see section 1.4 above) debated whether, and how, to incorporate events and new information about forecasts of future economic conditions that occur after the expected credit losses have been estimated. Due to operational practicality, entities may perform their expected credit loss calculations before the reporting period end in order to publish their financial statements in a timely manner (e.g., forecasts of future economic conditions developed in November may be used as the basis for determining the expected credit losses at the reporting date as at 31 December). Further information may then become available after the period end. The IFRS Transition Resource Group for Impairment of Financial Instruments noted that:

- If new information becomes available before the reporting date, subject to materiality considerations in accordance with IAS 8, an entity is required to take into consideration this information in the assessment of significant increases in credit risk and the measurement of expected credit losses at the reporting date.
- IFRS 9 does not specifically require new information that becomes available after the reporting date to be reflected in the measurement of expected credit losses at the reporting date. If new information becomes available between the reporting date and the date the financial statements are authorised for issue, an entity needs to apply judgement, based on the specific facts and circumstances, to determine whether it is an adjusting or non-adjusting event in accordance with IAS 10 *Events after the Reporting Period* (see Chapter 34). Similarly, materiality considerations apply in accordance with IAS 8.
- Expected credit losses are similar in nature to the measurement of fair value at the reporting date, in that movements in fair value after the reporting date are generally not reflected in the measurement of fair value at the reporting date. [IAS 10.11]. For example, a change in interest rates or the outcome of a public vote after the reporting date would not normally be regarded as adjusting events for the ECL calculation.
- However, expected credit losses are a probability-weighted estimate of credit losses at the reporting date (see section 5.6 above). Accordingly, the determination of expected credit losses should take into consideration relevant possible future scenarios based on a range of expectations at the reporting date, using the information available at that date. Hence, the probabilities attached to future expected movements in interest rates and expected outcomes of a future public vote based on information available at the reporting date would be reflected in the determination of expected credit losses at that date.
- Entities need robust processes and appropriate governance procedures for incorporating information, including forecasts of future economic conditions, to ensure transparent and consistent application of the impairment requirements in IFRS 9. This includes processes for updating expected credit losses for new information that becomes available after the initial modelling has taken place up until the reporting date.

5.9.5 Other issues concerning forward-looking information

Frequently asked questions

Question 5-8: Implementation issues related to forward-looking information.

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 16 September 2015 - Agenda paper no. 4)

At its meeting on 16 September 2015 (see section 1.4 above), the IFRS Transition Resource Group for Impairment of Financial Instruments examined two further questions about the use of forward-looking information:

- (a) The level at which forward-looking information should be incorporated - whether at the level of the entity or on a portfolio-by-portfolio basis?
- (b) How to determine what is reasonable and supportable forward-looking information and how to treat shock events with material, but uncertain, economic consequences, such as an independence referendum? The same considerations could apply to events such as natural disasters. The question is particularly relevant within the context of information about emerging issues and uncertain future events, which is not usually included in an entity's current budgeting and forecasting processes.

With respect to the first issue, the IFRS Transition Resource Group for Impairment of Financial Instruments members confirmed that forward-looking information should be relevant for the particular financial instrument or group of financial instruments to which the impairment requirements are being applied. Different factors may be relevant to different financial instruments and, accordingly, the relevance of particular items of information may vary between financial instruments, depending on the specific drivers of credit risk. This is highlighted in Illustrative Example 5 to IFRS 9 (see Illustration 6-10 in section 6.5.3 below), in which expectations about future levels of unemployment in a specific industry and specific region are only relevant to a sub-portfolio of mortgage loans in which the borrowers work in that industry in that specific region. Conversely, it was also noted that if different financial instruments or portfolios being assessed share some similar risk characteristics, then relevant forward-looking information should be applied in a comparable and consistent manner to reflect those similar characteristics.

With respect to the second issue, the IFRS Transition Resource Group for Impairment of Financial Instruments members noted:

- There will be a spectrum of forward-looking information available, some of which will be reasonable and supportable and some of which will have little or no supportable basis. Determining the information that is relevant and reasonable and supportable and its impact on the assessment of significant increases in credit risk and measurement of expected credit losses can require a high level of judgement. In addition, it can be particularly challenging and difficult to determine the economic consequences (or 'second-order effects') of uncertain future outcomes. For example, while it may be possible to assess the likelihood of a particular event occurring, it may be more difficult to determine the effect of the event on the risk of a default occurring and/or on the credit losses that would be associated with that event using reasonable and supportable information.
- The objective of the IFRS 9 requirements for measuring expected credit losses is to reflect probability-weighted outcomes. Accordingly, information should not be excluded from the assessment of expected credit losses simply because:
 - (a) The event has a low or remote likelihood of occurring
 - Or
 - (b) The effect of that event on the credit risk or the amount of expected credit losses is uncertain
- An entity should make an effort in good faith to estimate the impact of uncertain future events, including second-order effects, on the credit risk of financial instruments and the measurement of expected credit losses. The estimate should be based on all reasonable and supportable information that is relevant and available without undue cost and effort. Furthermore:
 - (a) Estimates of expected credit losses should reflect an entity's own expectations of credit losses; however, entities should be able to explain how they have arrived at their estimate and how it is based on reasonable and supportable information.
 - (b) Estimates of expected credit losses are, by their nature, approximations, which will be updated as more reasonable and supportable information becomes available over time.
 - (c) Information does not necessarily need to flow through a statistical model or credit-rating process in order to determine whether it is reasonable and supportable and relevant for a particular financial instrument or group of financial instruments.

- If an entity could determine that an uncertain event has an impact on the probability of default, then it should be possible to make an estimate of the impact on expected credit losses, despite the potentially large range of outcomes. However, in some exceptional cases, it was acknowledged that it may not be possible to estimate the impact on expected credit losses, despite an entity's best efforts.
- In this regard, the importance of disclosure of forward-looking information that is relevant, but that cannot be incorporated into the determination of significant increases in credit risk and/or the measurement of expected credit losses because of the lack of reasonable and supportable information was emphasised. Such disclosures should be consistent with the objective in IFRS 7, which is to enable users of the financial statements to understand the credit risk to which the entity is exposed.
- The need for good governance and processes in this area, because of the uncertainties and continually changing circumstances associated with forward-looking information. Furthermore, an entity should be able to explain what information it had considered and why that information had been included or excluded from the determination of expected credit losses.

This IFRS Transition Resource Group for Impairment of Financial Instruments discussion predated that in December 2015 on the use of probability-weighted multiple economic scenarios (see section 5.6.1 above) and some of the points that were noted by the IFRS Transition Resource Group for Impairment of Financial Instruments probably need to be updated in the context of the later discussion. For instance, the IFRS Transition Resource Group for Impairment of Financial Instruments members noted that the impact of scenarios about some uncertain future events for which there is reasonable and supportable information, may need to be incorporated through the use of overlays to the 'base model' on a collective basis. In applying a multiple scenario approach, an entity will not use just one base model. Moreover, if the lender needs to estimate expected credit losses by considering multiple economic scenarios, it would follow that many shock events may already be included in that process (since some shock events might be assumed to occur every year), with the event and its various possible consequences occurring in some scenarios and not in others. There may still need to be cases when the effect of shock events is added through an additional 'overlay' to the modelled calculation of expected credit losses but, if so, as noted by the IFRS Transition Resource Group for Impairment of Financial Instruments members, care needs to be taken to avoid double counting the consequences of the event with what has already been assumed in the model. Banks will also need to take account of guidance from their regulators (see section 7.1 below).

The IFRS Transition Resource Group for Impairment of Financial Instruments members also noted that the effects of uncertain future events may need to be reflected in the assessment of whether there has been a significant increase in credit risk.

An example of an uncertain future event that arose after the IFRS Transition Resource Group for Impairment of Financial Instruments discussion is the coronavirus pandemic (see section 7.8 below). On 27 March 2020, the IASB issued an educational document in which it acknowledged that it was likely to be difficult to incorporate the specific effects of the coronavirus pandemic and government support measures on a reasonable and supportable basis. However, changes in economic conditions should be reflected in macroeconomic scenarios applied by entities and in their weightings (see sections 5.6.1 and 5.6.2 above).²⁰ When it is not possible to reflect such information in models, the IASB expects post-model overlays or adjustments to be considered.

In addition, the IASB noted that although the circumstances of the coronavirus pandemic were difficult and created high levels of uncertainty, if ECL estimates were based on reasonable and supportable information and IFRS 9 was not applied mechanistically, useful information could be provided about expected credit losses. Indeed, in the stressed environment created by the pandemic, IFRS 9 and the associated disclosures provided much needed transparency to users of financial statements (see section 15 below and Chapter 50).

²⁰ [IFRS 9 and covid-19](#): Accounting for expected credit losses applying IFRS 9 Financial Instruments in the light of current uncertainty resulting from the covid-19 pandemic, IASB, 27 March 2020. Available on the IFRS Foundation's website.

6 General approach: determining significant increases in credit risk

One of the major challenges in implementing the general approach in the IFRS 9 expected credit loss model is to track and determine whether there have been significant increases in the credit risk of an entity's credit exposures since initial recognition.

The assessment of significant deterioration is key in establishing the point of switching between the requirement to measure an allowance based on 12-month expected credit losses and one that is based on lifetime expected credit losses. The assessment of whether there has been a significant increase in credit risk is therefore often referred to as 'the staging assessment'. IFRS 9 is prescriptive that an entity cannot align the timing of significant increases in credit risk and the recognition of lifetime expected credit losses with the time when a financial asset is regarded as credit-impaired or to an entity's internal definition of default. [IFRS 9.B5.5.21]. Financial assets will normally be assessed as having increased significantly in credit risk earlier than when they become credit-impaired (see section 3.1 above) or default occurs. [IFRS 9.B5.5.7].

As this area involves significant management judgement, entities are required to provide both qualitative and quantitative disclosures under IFRS 7 to explain the inputs, assumptions and estimation used to determine significant increases in credit risk of financial instruments and any changes in those assumptions and estimates (see section 15 below and Chapter 50). [IFRS 7.35F(a), IFRS 7.35G(a)(ii), IFRS 7.35G(c)].

Frequently asked questions

Question 6-1: Whether in respect of financial instruments with a maturity of 12 months or less there is a requirement to assess significant increases in credit risk?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 11 December 2015 - Agenda paper no. 8)

At its meeting in December 2015 (see section 1.4 above), the IFRS Transition Resource Group for Impairment of Financial Instruments members reaffirmed that unless a more specific exception applies, IFRS 9 requires an entity to assess whether there has been a significant increase in credit risk for all financial instruments, including those with a maturity of 12 months or less. Consistently with this requirement, IFRS 7 requires corresponding disclosures that distinguish between financial instruments for which the loss allowance is equal to 12-month or lifetime expected credit losses. In addition, the IFRS Transition Resource Group for Impairment of Financial Instruments members noted that:

- The assessment of significant increases in credit risk is distinct from the measurement of expected credit losses as highlighted by IFRS 9.5.5.9. For example, a collateralised financial asset may have suffered a significant increase in credit risk, but owing to the value of the collateral there may not be an increase in the amount of expected credit losses even if measured on a lifetime rather than a 12-month basis.
- Assessing changes in credit risk would be consistent with normal credit risk management practices.
- The expected life of a financial instrument may change if it has suffered a significant increase in credit risk.

Finally, the IFRS Transition Resource Group for Impairment of Financial Instruments noted the importance of the IFRS 7 disclosure requirements and observed that disclosing information regarding the increase in credit risk since initial recognition provides users of financial statements with useful information regarding the changes in the risk of default occurring in respect of that financial instrument (see section 15 below and Chapter 50).

6.1 Change in the risk of a default occurring

In order to make the assessment of whether there has been significant credit deterioration, an entity considers reasonable and supportable information that is available without undue cost or effort and compare the risk of a default occurring on the financial instruments over its life as at the reporting date and as at the date of initial recognition.

Extract from IFRS 9

5.5.9 At each reporting date, an entity shall assess whether the credit risk on a financial instrument has increased significantly since initial recognition. When making the assessment, an entity shall use the change in the risk of a default occurring over the expected life of the financial instrument instead of the change in the amount of expected credit losses. To make that assessment, an entity shall compare the risk of a default occurring on the financial instrument as at the reporting date with the risk of a default occurring on the financial instrument as at the date of initial recognition and consider reasonable and supportable information, that is available without undue cost or effort, that is indicative of significant increases in credit risk since initial recognition.

[IFRS 9.5.5.9].

For loan commitments, an entity considers changes in the risk of a default occurring on the potential loan to which a loan commitment relates.

For financial guarantee contracts, an entity considers the changes in the risk that the specified debtor will default. [IFRS 9.B5.5.8].

An entity is required to assess significant increases in credit risk based on the change in the risk of a default occurring over the expected life of the financial instrument rather than the change in the amount of expected credit losses. [IFRS 9.5.5.9]. In a departure from the Basel regulatory wording and to avoid suggesting that statistical models are required (including the probability of default approach), the IASB changed the terminology from 'probability of a default occurring' to 'risk of a default occurring'.

[IFRS 9.BC5.157].

In order to make the IFRS 9 impairment model operational, the IASB considered a number of alternative methods for determining significant increases in credit risk, but these were rejected for the following reasons:

- **Absolute level of credit risk:** The IASB considered whether an entity should be required to recognise lifetime expected credit losses on all financial instruments at, or above, a particular credit risk at the reporting date. Although this approach is operationally simpler to apply (because an entity is not required to track changes in credit risk), such an approach would provide very different information. It would not approximate the economic effect of changes in credit loss expectations subsequent to initial recognition. In addition, it may also result in overstatement or understatement of expected credit losses, depending on the threshold set for recognising lifetime expected credit losses. [IFRS 9.BC5.160]. However, the IASB noted that an absolute approach could be used for portfolios of financial instruments with similar credit risk at initial recognition, by determining the maximum initial credit risk accepted and then comparing the maximum initial credit risk to the credit risk at the reporting date (see section 6.4.5 below). [IFRS 9.BC5.161].
- **Change in the credit risk management objective:** The IASB also considered whether the assessment of significant deterioration should be based on whether an entity's credit risk management objective changes (e.g., monitoring of financial assets on an individual basis, or a change from collecting past due amounts to the recovery of these amounts). This approach is operationally relatively easy to apply. However, it may result in a delayed recognition of expected credit losses. [IFRS 9.BC5.162].
- **Credit underwriting policies:** The IASB further considered whether the change in the entity's credit underwriting limit for a particular class of financial instrument at the reporting date (i.e., an entity would not originate new loans on the same terms) should form the basis of assessing significant increase in credit risk. The IASB noted that this approach is similar to the absolute approach above. Moreover, the change in an entity's credit underwriting limits may be driven by other factors that are not related to a change in the credit risk of its borrowers (e.g., the entity may incorporate favourable terms to maintain a good business relationship or to increase lending), or are dependent on circumstances existing at the reporting date that are not relevant to the particular vintages of financial instruments. [IFRS 9.BC5.163, IFRS 9.BC5.164, IFRS 9.BC5.165].
- Similar to measuring expected credit losses, an entity may use different approaches when assessing significant increases in credit risk for different financial instruments: [IFRS 9.B5.5.12]

Extract from IFRS 9

B5.5.12 An entity may apply various approaches when assessing whether the credit risk on a financial instrument has increased significantly since initial recognition or when measuring expected credit losses. An entity may apply different approaches for different financial instruments. An approach that does not include an explicit probability of default as an input *per se*, such as a credit loss rate approach, can be consistent with the requirements in this Standard, provided that an entity is able to separate the changes in the risk of a default occurring from changes in other drivers of expected credit losses, such as collateral, and considers the following when making the assessment:

- (a) the change in the risk of a default occurring since initial recognition;
- (b) the expected life of the financial instrument; and
- (c) reasonable and supportable information that is available without undue cost or effort that may affect credit risk.

In addition, because of the relationship between the expected life and the risk of default occurring, the change in credit risk cannot be assessed simply by comparing the change in the absolute risk of default over time, because the risk of default usually decreases as time passes if the credit risk is unchanged.

[IFRS 9.B5.5.11, IFRS 9.B5.5.12].

Entities that do not use probability of loss as an explicit input will have to use other criteria to identify a change in the risk of default occurring. These might include deterioration in a behavioural score, or other indicators, of a heightened risk of default. A collective approach may also be an appropriate supplement or substitute for an assessment at the individual instrument level (see section 6.5 below).

A number of operational simplifications and presumptions are available to help entities make this assessment (as described further below).

6.1.1 Impact of collateral, credit enhancements and financial guarantee contracts

As already stressed, the staging assessment is based on the change in the lifetime risk of default, not the amount of expected credit losses. [IFRS 9.5.5.9]. Hence the allowance for a fully collateralised asset may need to be based on lifetime expected credit losses (because there has been a significant increase in the risk of default) even though no loss is expected to arise. In such instances, the fact that the asset is being measured using lifetime expected credit losses may have more significance for disclosure than for measurement (see section 15 below).

The interaction between collateral, assessment of significant increases in credit risk and measurement of expected credit losses is illustrated in the following example from IFRS 9. [IFRS 9.IE Example 3, IFRS 9.IE18-IE23].

Illustration 6-1: Highly collateralised financial asset

Company H owns real estate assets which are financed by a five-year loan from Bank Z with a loan-to-value ratio of 50%. The loan is secured by a first-ranking security over the real estate assets. At initial recognition of the loan, Bank Z does not consider the loan to be credit-impaired as defined in Appendix A of IFRS 9.

Subsequent to initial recognition, the revenues and operating profits of Company H have decreased because of an economic recession. Furthermore, expected increases in regulations have the potential to further negatively affect revenue and operating profit. These negative effects on Company H's operations could be significant and ongoing.

As a result of these recent events and expected adverse economic conditions, Company H's free cash flow is expected to be reduced to the point that the coverage of scheduled loan payments could become tight. Bank Z estimates that a further deterioration in cash flows may result in Company H missing a contractual payment on the loan and becoming past due.

Recent third-party appraisals have indicated a decrease in the value of the real estate properties, resulting in a current loan-to-value ratio of 70%.

At the reporting date, the loan to Company H is not considered to have low credit risk in accordance with IFRS 9.5.5.10. Bank Z therefore needs to assess whether there has been a significant increase in credit risk since initial recognition in accordance with IFRS 9.5.5.3, irrespective of the value of the collateral it holds. It notes that the loan is subject to considerable credit risk at the reporting date because even a slight deterioration in cash flows could result in Company H missing a contractual payment on the loan. As a result, Bank Z determines that the credit risk (i.e., the risk of a default occurring) has increased significantly since initial recognition. Consequently, Bank Z recognises lifetime expected credit losses on the loan to Company H.

Although lifetime expected credit losses should be recognised, the measurement of the expected credit losses will reflect the recovery expected from the collateral (adjusting for the costs of obtaining and selling the collateral) on the property as required by IFRS 9.B5.5.55 and may result in the expected credit losses on the loan being very small.

Frequently asked questions

Question 6-2: Whether an entity should consider the ability to recover cash flows through the integral financial guarantee contract when assessing whether there has been a significant increase in the credit risk of the guaranteed debt instrument since initial recognition?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 22 April 2015 - Agenda paper no. 5)

At its meeting on 22 April 2015, The IFRS Transition Resource Group for Impairment of Financial Instruments (see section 1.4 above) noted that IFRS 9 requires that measurement of the expected credit losses of the guaranteed debt instrument includes cash flows from the integral financial guarantee contract (see section 5.8.1 above). [IFRS 9.B5.5.55]. However, some IFRS Transition Resource Group for Impairment of Financial Instruments members commented that IFRS 9 is clear that recoveries from integral financial guarantee contracts should be excluded from the assessment of significant increases in credit risk of the guaranteed debt instrument. [IFRS 9.5.5.9]. This is because the focus of IFRS 9 is about the risk of the borrower defaulting when making such an assessment, as highlighted in the examples in B5.5.17 of IFRS 9. These examples clarify that information about a guarantee (or other credit enhancement) may be relevant to assessing changes in credit risk, but only to the extent that it affects the likelihood of the borrower defaulting on the instrument (see section 6.2.1 below for the list of examples). [IFRS 9.B5.5.17]. Furthermore, excluding recoveries from the financial guarantee contract, when assessing significant increases in credit risk, would be consistent with the treatment of other forms of collateral.

When assessing whether financial assets are credit-impaired, an entity does not take into account any recoveries from the realisation of the collateral.

While the value of collateral does not normally affect the assessment of significant increases in credit risk, if significant changes in the value of the collateral supporting the obligation are expected to reduce the borrower's economic incentive to make scheduled contractual payments, then this would have an effect on the risk of a default occurring. IFRS 9 provides an example where, if the value of collateral declines because house prices decline, borrowers in some jurisdictions have a greater incentive to default on their mortgages. [IFRS 9.B5.5.17(j)].

The other examples provided by IFRS 9 of situations where the value of a credit enhancement could have an impact on the ability or economic incentive of the borrower to repay relate to guarantees or financial support provided by a shareholder, parent entity or other affiliate and to interests issued in securitisations:

- A significant change in the quality of the guarantee provided by a shareholder (or an individual's parent) if the shareholder (or parent) has an incentive and financial ability to prevent default by capital or cash infusion. [IFRS 9.B5.5.17(k)].
- Significant changes, such as reductions, in financial support from a parent entity or other affiliate or an actual or expected significant change in the quality of credit enhancement, that are expected to reduce the borrower's ability to make scheduled contractual payments. For example, such a situation could occur if a parent decides to no longer provide financial support to a subsidiary, which as a result would face bankruptcy or receivership. This could, in turn, result in that subsidiary prioritising payments for its operational needs (such as payroll and crucial suppliers) and assigning a lower priority to payments on its financial debt, resulting in an increase in the risk of default on those liabilities. Credit quality enhancements or support include the consideration of the financial condition of the guarantor and/or, for interests issued in securitisations, whether subordinated interests are expected to be capable of absorbing expected credit losses (for example, on the loans underlying the security). [IFRS 9.B5.5.17(l)].

6.1.2 Contractually linked instruments and subordinated interests

The last example in the previous section, referring to the effect of subordinated interests in a securitisation deserves some comment. IFRS 9 sets out rules to determine whether an investment in a contractually linked instrument such as a tranche of a securitisation, qualifies to be measured at amortised cost or at fair value through other comprehensive income (see Chapter 44). [IFRS 9.4.1.2, IFRS 9.4.1.2A, IFRS 9.B4.1.20-26]. Some contractually linked instruments that are more senior tranches may pass the contractual cash flow characteristics test and consequently will be measured at amortised cost or fair value through other comprehensive income. However, the contractual cash flows of the individual tranches are normally based on a pre-defined waterfall structure (i.e., principal and interest are first paid on the most senior tranche and then successively paid on more junior tranches). To this extent, contractually linked instruments do not default. Meanwhile, Appendix A of IFRS 9 defines 'credit loss' as "the difference between all contractual cash flows that are due to an entity in accordance with the contract and all the cash flows that the entity expects to receive (i.e., reflecting any cash shortfalls), discounted at the original effective interest rate (or credit-adjusted effective interest rate for purchased or originated credit-impaired financial assets)". Under the contract, the issuer of a contractually linked instrument only passes on cash flows that it actually receives, so the contractually defined cash flows under the waterfall structure are always equal to the cash flows that a holder expects to receive. Accordingly, one could argue that contractually linked instruments never give rise to a credit loss, and so would never be regarded as impaired.

However, consistent with recording these assets at amortised cost or at fair value through other comprehensive income because they meet the solely payment of principal and interest criterion, the contractual terms of the contractually linked instrument are 'deemed' to give rise on specified dates to cash flows that are solely payments of principal and interest on the principal amount outstanding. Hence, we believe that for the purposes of the effective interest method and impairment requirements of IFRS 9, the lender needs to consider the deemed principal and interest payments as the contractual cash flows, instead of the contractual cash flows determined under the waterfall structure. Accordingly, any failure of the instrument to pay the investor the full amount deemed to be due must be treated as a default and an estimation of the amount of any losses that will be incurred must be reflected in the credit loss allowance.

How we see it

IFRS 9 deems certain tranches of contractually linked instruments to satisfy the solely payment of principal and interest criterion to be recorded at amortised cost or at fair value through other comprehensive income. Consequently, the holder of a tranche to which this applies needs to consider the 'deemed' principal and interest payments as the contractual cash flows, instead of the contractual cash flows determined under the waterfall structure, for the purposes of the effective interest method and impairment requirements of IFRS 9.

It also follows that any changes in circumstances that may reduce the ability of the holder of a contractually linked instrument to receive the principal and interest would need to be considered in assessing whether there has been a significant increase in credit risk. This would include whether more subordinated interests are expected to continue to be capable of absorbing expected credit losses on the underlying loans. Therefore, the investment is measured based on lifetime expected credit losses if there are sufficient losses expected on the instruments underlying the securitisation such that they could not all be absorbed by subordinated interests in the structure, and so there is a significantly increased risk that the holder of a senior tranche will suffer a loss.

For contractually linked instruments where the issuer does not make payments to the holder to the extent that it does not receive sufficient cash from the underlying pool of assets or where there are non-recourse features, such as features that limit an entity's right to receive cash flows, the entity is first required to determine the revised gross carrying amount of the CLI instrument. The entity does this by taking into account the revised estimated contractual cash flows, then assessing the ECL of the revised gross carrying amount accordingly.

6.1.3 Determining change in the risk of a default under the loss rate approach

Under the loss rate approach, introduced in section 5.4.2 above, an entity develops loss-rate statistics on the basis of the amount written off over the life of the financial assets rather than using separate probability of default and loss given default statistics. Entities then must adjust these historical credit loss trends for current conditions and expectations about the future.

IFRS 9 is clear that although a loss rate approach may be applied, an entity needs to be able to separate the changes in the risk of a default occurring from changes in other drivers of expected credit losses for the purpose of assessing if there has been a significant increase in credit risk. [IFRS 9.B5.5.12]. Under the loss rate approach, the entity does not distinguish between a risk of a default occurring and the loss incurred following a default. This is not so much of an issue for measuring 12-month or lifetime expected credit losses. However, under the loss rate approach, an entity would not be able to implement the assessment of significant increases in credit risk that is based on the change in the risk of a default. Therefore, entities using the loss rate approach would need an overlay of measuring and forecasting the level of defaults, as illustrated in the extract of Example 9 from the Illustrative Examples to IFRS 9 (see Illustration 5-3 in section 5.4.2 above). For entities that currently use only expected loss rates it may be easier to develop a probability of default approach than to use the method described in this example.

6.2 Factors or indicators of changes in credit risk

Extract from IFRS 9

B5.5.16 Credit risk analysis is a multifactor and holistic analysis; whether a specific factor is relevant, and its weight compared to other factors, will depend on the type of product, characteristics of the financial instruments and the borrower as well as the geographical region. An entity shall consider reasonable and supportable information that is available without undue cost or effort and that is relevant for the particular financial instrument being assessed. However, some factors or indicators may not be identifiable on an individual financial instrument level. In such a case, the factors or indicators should be assessed for appropriate portfolios, groups of portfolios or portions of a portfolio of financial instruments to determine whether the requirement in paragraph 5.5.3 for the recognition of lifetime expected credit losses has been met.

Similar to measuring expected credit losses (see section 5 above), when assessing significant increases in credit risk, an entity considers all reasonable and supportable information that is available without undue cost or effort (see section 5.9.1 above) and that is relevant for an individual financial instrument, a portfolio, portions of a portfolio, and groups of portfolios. [IFRS 9.B5.5.15, IFRS 9.B5.5.16].

The IASB notes that it did not intend to prescribe a specific or mechanistic approach to assess changes in credit risk and that the appropriate approach will vary for different levels of sophistication of entities, the financial instrument and the availability of data. [IFRS 9.BC5.157]. It is important to stress that the assessment of significant increases in credit risk often involves a multifactor and holistic analysis. The importance and relevance of each specific factor will depend on the type of product, characteristics of the financial instruments and the borrower as well as the geographical region. [IFRS 9.B5.5.16].

The guidance in IFRS 9 is clear that in certain circumstances, qualitative and non-statistical quantitative information may indicate a significant increase in credit risk: [IFRS 9.B5.5.18]

Extract from IFRS 9

B5.5.18 In some cases, the qualitative and non-statistical quantitative information available may be sufficient to determine that a financial instrument has met the criterion for the recognition of a loss allowance at an amount equal to lifetime expected credit losses. That is, the information does not need to flow through a statistical model or credit ratings process in order to determine whether there has been a significant increase in the credit risk of the financial instrument. In other cases, an entity may need to consider other information, including information from its statistical models or credit ratings processes. Alternatively, the entity may base the assessment on both types of information, ie qualitative factors that are not captured through the internal ratings process and a specific internal rating category at the reporting date, taking into consideration the credit risk characteristics at initial recognition, if both types of information are relevant.

6.2.1 Examples of factors or indicators of changes in credit risk

IFRS 9 provides a non-exhaustive list of factors or indicators which an entity considers when determining whether the recognition of lifetime expected credit losses is required: [IFRS 9.B5.5.17]

Extract from IFRS 9

B5.5.17 The following non-exhaustive list of information may be relevant in assessing changes in credit risk:

- (a) significant changes in internal price indicators of credit risk as a result of a change in credit risk since inception, including, but not limited to, the credit spread that would result if a particular financial instrument or similar financial instrument with the same terms and the same counterparty were newly originated or issued at the reporting date.
- (b) other changes in the rates or terms of an existing financial instrument that would be significantly different if the instrument was newly originated or issued at the reporting date (such as more stringent covenants, increased amounts of collateral or guarantees, or higher income coverage) because of changes in the credit risk of the financial instrument since initial recognition.
- (c) significant changes in external market indicators of credit risk for a particular financial instrument or similar financial instruments with the same expected life. Changes in market indicators of credit risk include, but are not limited to:
 - (i) the credit spread;
 - (ii) the credit default swap prices for the borrower;
 - (iii) the length of time or the extent to which the fair value of a financial asset has been less than its amortised cost; and
 - (iv) other market information related to the borrower, such as changes in the price of a borrower's debt and equity instruments.
- (d) an actual or expected significant change in the financial instrument's external credit rating.
- (e) an actual or expected internal credit rating downgrade for the borrower or decrease in behavioural scoring used to assess credit risk internally. Internal credit ratings and internal behavioural scoring are more reliable when they are mapped to external ratings or supported by default studies.
- (f) existing or forecast adverse changes in business, financial or economic conditions that are expected to cause a significant change in the borrower's ability to meet its debt obligations, such as an actual or expected increase in interest rates or an actual or expected significant increase in unemployment rates.
- (g) an actual or expected significant change in the operating results of the borrower. Examples include actual or expected declining revenues or margins, increasing operating risks, working capital deficiencies, decreasing asset quality, increased balance sheet leverage, liquidity, management problems or changes in the scope of business or organisational structure (such as the discontinuance of a segment of the business) that results in a significant change in the borrower's ability to meet its debt obligations.
- (h) significant increases in credit risk on other financial instruments of the same borrower.
- (i) an actual or expected significant adverse change in the regulatory, economic, or technological environment of the borrower that results in a significant change in the borrower's ability to meet its debt obligations, such as a decline in the demand for the borrower's sales product because of a shift in technology.
- (j) significant changes in the value of the collateral supporting the obligation or in the quality of third-party guarantees or credit enhancements, which are expected to reduce the borrower's economic incentive to make scheduled contractual payments or to otherwise have an effect on the probability of a default occurring. For example, if the value of collateral declines because house prices decline, borrowers in some jurisdictions have a greater incentive to default on their mortgages.
- (k) a significant change in the quality of the guarantee provided by a shareholder (or an individual's parents) if the shareholder (or parents) have an incentive and financial ability to prevent default by capital or cash infusion.

- (l) significant changes, such as reductions in financial support from a parent entity or other affiliate or an actual or expected significant change in the quality of credit enhancement, that are expected to reduce the borrower's economic incentive to make scheduled contractual payments. Credit quality enhancements or support include the consideration of the financial condition of the guarantor and/or, for interests issued in securitisations, whether subordinated interests are expected to be capable of absorbing expected credit losses (for example, on the loans underlying the security).
- (m) expected changes in the loan documentation including an expected breach of contract that may lead to covenant waivers or amendments, interest payment holidays, interest rate step-ups, requiring additional collateral or guarantees, or other changes to the contractual framework of the instrument.
- (n) significant changes in the expected performance and behaviour of the borrower, including changes in the payment status of borrowers in the group (for example, an increase in the expected number or extent of delayed contractual payments or significant increases in the expected number of credit card borrowers who are expected to approach or exceed their credit limit or who are expected to be paying the minimum monthly amount).
- (o) changes in the entity's credit management approach in relation to the financial instrument; ie based on emerging indicators of changes in the credit risk of the financial instrument, the entity's credit risk management practice is expected to become more active or to be focused on managing the instrument, including the instrument becoming more closely monitored or controlled, or the entity specifically intervening with the borrower.
- (p) past due information, including the rebuttable presumption as set out in paragraph 5.5.11.

We make the following observations:

- With respect to the use of external market indicators of credit risk, the IASB noted that market prices are an important source of information that should be considered in assessing whether credit risk has changed. However, market prices cannot solely determine whether significant deterioration has occurred since they are also affected by non-credit risk related factors such as changes in interest rates or liquidity risks. [IFRS 9.BC5.123].
- An increase in the risk of default on a loan could occur if a parent decides to no longer provide financial support to a subsidiary. This could in turn result in that subsidiary prioritising payments for its operational needs (such as payroll and crucial suppliers) and assigning a lower priority to payments on its financial debt, resulting in an increase in the risk of default on those liabilities.
- If entities make the staging assessment using their credit risk management systems, they will need to consider whether their systems take into account the various indicators listed above.
- Many financial institutions have readily available information about the pricing and terms of various types of loans issued to a specific customer (e.g., overdraft, credit cards and mortgage loans) in their credit risk management systems and processes. However, in practice, it would often be difficult to use such information because changes in pricing and terms on the origination of a similar financial instrument at the reporting date are not obviously related to a change in credit risk as other, more commercial, factors come into play (e.g., different risk appetites, change in management approach and underwriting standards). It may be challenging to link the two sets of information (i.e., pricing processes on the one hand and credit risk management on the other).
- Some collateralised loans are subject to cash variation margining requirements, which means that the trigger for default is normally the inability to pay a margin call. Therefore, in such circumstances the probability of default may be driven by the value of the collateral and changes in collateral values may need to be reflected in the staging assessment.
- Some of the factors or indicators are only relevant for the assessment of significant deterioration on an individual basis and not on a portfolio basis. These include, for example, a change in external market indicators of credit risk, including the credit spread, the credit default swap prices of the borrower or a decline in fair value of the asset. However, it is worth noting that external market information that is available for a quoted instrument may also be useful to help assess another instrument that is not quoted but which is issued by the same debtor or one who operates in the same sector.

- It is important to stress that the approach required by IFRS 9 is more holistic and qualitative than is necessarily captured by external credit ratings. Illustration 6-6 in section 6.4.1 below illustrates that there has in the past been significant differences between using agencies' credit ratings or using market data such as credit default swap spreads. The same point can of course be made about the use of internal credit ratings, especially if they are only reassessed on an annual basis. At the September 2015 meeting, the IFRS Transition Resource Group for Impairment of Financial Instruments observed that "credit grading systems were not designed with the requirements of IFRS 9 in mind and consequently, it should not be assumed that they will always be an appropriate means of identifying significant increases in credit risk".²¹ The appropriateness of using internal credit grading systems as a means of assessing changes in credit risk since initial recognition depends on whether the credit grades are reviewed with sufficient frequency, include all reasonable and supportable information and reflect the risk of default over the expected life of the financial instrument.
- As credit grading systems vary, care needs to be taken when referring to movements in credit grades and how this reflects an increased risk of default occurring. In addition, the assessment of whether a change in credit risk grade represents a significant increase in credit risk in accordance with IFRS 9 depends on the initial credit risk of the financial instrument being assessed. Moreover, the relationship between credit grades and changes in the risk of default occurring differs between credit grading systems. For instance, in some cases, the changes in the risk of a default occurring will increase exponentially between grades whereas in others it will not.
- Also, some of the above factors or indicators are very forward-looking, such as forecasts of adverse changes in business, financial or economic conditions that are expected to result in significant future financial difficulty of the borrower in repaying its debt. In practice, the analysis may have to be performed at the level of a portfolio rather than at an individual level when forward-looking information is not available at the individual level.

How we see it

With IFRS 9 not being prescriptive, we observe differences in how banks have implemented the assessment of significant increase in credit risk. These differences reflect various schools of thought along with differences in credit processes, business model, sophistication of the lender, the use of advanced models for regulatory capital purposes, availability of data (e.g., historic data at origination) and consistency of definitions across businesses or multiple systems. As use of models and availability of data can vary within a bank, a number of approaches may even be adopted within a single institution.

In general, entities use a combination of quantitative and qualitative drivers to assess significant increases in credit risk. Some of these are regarded as primary, others as secondary and some as backstops. The primary driver is usually expected to be the most forward-looking indicator and is generally based on a relative measure. The most common primary drivers used by the larger banks are:

- Changes in the lifetime risk of a default occurring, guided by scores and ratings
 - Changes in the lifetime or 12-month probability of default
 - Changes in ratings or credit scores for retail exposures and ratings for corporate exposures
- Forbearance and watchlists are often used as secondary drivers and delinquency, usually more than 30 days past due, as a backstop (see section 6.2.2 below).

21 IASB Transition Resource Group for Impairment of Financial Instruments, [Meeting Summary](#), 16 September 2015, para. 17.

6.2.2 Past due status and more than 30 days past due rebuttable presumption

Extract from IFRS 9

- 5.5.11 If reasonable and supportable forward-looking information is available without undue cost or effort, an entity cannot rely solely on past due information when determining whether credit risk has increased significantly since initial recognition. However, when information that is more forward-looking than past due status (either on an individual or a collective basis) is not available without undue cost or effort, an entity may use past due information to determine whether there have been significant increases in credit risk since initial recognition. Regardless of the way in which an entity assesses significant increases in credit risk, there is a rebuttable presumption that the credit risk on a financial asset has increased significantly since initial recognition when contractual payments are more than 30 days past due. An entity can rebut this presumption if the entity has reasonable and supportable information that is available without undue cost or effort, that demonstrates that the credit risk has not increased significantly since initial recognition even though the contractual payments are more than 30 days past due. When an entity determines that there have been significant increases in credit risk before contractual payments are more than 30 days past due, the rebuttable presumption does not apply.
- B5.5.2 Lifetime expected credit losses are generally expected to be recognised before a financial instrument becomes past due. Typically, credit risk increases significantly before a financial instrument becomes past due or other lagging borrower-specific factors (for example, a modification or restructuring) are observed. Consequently when reasonable and supportable information that is more forward-looking than past due information is available without undue cost or effort, it must be used to assess changes in credit risk.

The IASB is concerned that past due information is a lagging indicator. Typically, credit risk increases significantly before a financial instrument becomes past due or other lagging borrower-specific factors (for example, a modification or restructuring) are observed. Consequently, when reasonable and supportable information that is more forward-looking than past due information is available without undue cost or effort, it must be used to assess changes in credit risk and an entity cannot rely solely on past due information.

[IFRS 9.5.5.11, IFRS 9.B5.5.2]. However, the IASB acknowledged that many entities manage credit risk on the basis of information about past due status and have a limited ability to assess credit risk on an instrument-by-instrument basis in more detail on a timely basis. [IFRS 9.BC5.192]. Therefore, if more forward-looking information (either on an individual or collective basis) is not available without undue cost or effort, an entity may use past due information to assess changes in credit risks. [IFRS 9.5.5.11]. However, contract assets by definition, cannot be past due, therefore, entities cannot rely on delinquency for staging of such assets.

Whether the entity uses only past due information or also more forward-looking information (e.g., macroeconomic indicators), there is a rebuttable presumption that the credit risk on a financial asset has increased significantly since initial recognition when contractual payments are more than 30 days past due. However, IFRS 9 seems to make it clear that it is not possible to rebut the 30 days past due presumption just because of a favourable economic outlook. [IFRS 9.5.5.11, IFRS 9.B5.5.19]. The IASB decided that this rebuttable presumption was required to ensure that application of the assessment of the increase in credit risk does not result in a reversion to an incurred loss notion. [IFRS 9.BC5.190].

Moreover, as already stressed earlier, IFRS 9 is clear that an entity cannot align the definition and criteria used to identify significant increases in credit risk (and the resulting recognition of lifetime expected credit losses) to when a financial asset is regarded as credit-impaired or to an entity's internal definition of default. [IFRS 9.B5.5.21]. An entity will normally identify significant increases in credit risk and recognise lifetime expected credit losses before default occurs or the financial asset becomes credit-impaired, either on an individual or collective basis (see section 6.5 below).

Extract from IFRS 9

- B5.5.20 An entity can rebut this presumption. However, it can do so only when it has reasonable and supportable information available that demonstrates that even if contractual payments become more than 30 days past due, this does not represent a significant increase in the credit risk of a financial instrument. For example when non-payment was an administrative oversight, instead of resulting from financial difficulty of the borrower, or the entity has access to historical evidence that demonstrates that there is no correlation between significant increases in the risk of a default occurring and financial assets on which payments are more than 30 days past due, but that evidence does identify such a correlation when payments are more than 60 days past due.

An entity can rebut the 30 days past due presumption if it has reasonable and supportable information that is available without undue cost or effort, that demonstrates that credit risk has not increased significantly even though contractual payments are more than 30 days past due. [IFRS 9.5.5.11, IFRS 9.B5.5.20]. Also, in the context of the coronavirus pandemic, the 30 days past due backstop assumption may have needed to be rebutted in circumstances where the borrowers were experiencing temporary liquidity issues and whose long-term credit risk was unlikely to have been significantly affected by the pandemic (see section 7.8 below).

6.2.3 Concessions granted to a wide range of customers

In the context of the coronavirus pandemic, one of the accounting issues has been whether concessions made by lenders, such as changes in payment terms and the granting of payment holidays, will result in loans being move from stage 1 to stage 2.

The IASB noted in their educational material published on 27 March 2020 that IFRS 9 requires the application of judgement and both requires and allows entities to adjust their approach to determining expected credit losses in different circumstances (see section 7.8.2 below).²² A number of assumptions and linkages underlying the way expected credit losses have been implemented may no longer hold in an environment affected by a pandemic. Entities should not continue to apply their existing expected credit loss methodology mechanically. For example, the extension of payment holidays to all borrowers in particular classes of financial instruments should not automatically result in all those instruments being considered to have suffered a significant increase in credit risk. This would be the case even if a moratorium results in a loss for the lender (e.g., if interest payments are reduced or waived), if it is provided irrespective of the borrowers' individual circumstances and the extension of payment holidays are assessed to be modifications rather than derecognition of the financial instruments (see section 8 below).

In other situations, if relief measures are available only to those who meet certain criteria, entities need to carefully assess whether such criteria themselves might indicate a significant increase in credit risk for the affected borrowers. For instance, a significant increase in credit risk is more likely to have occurred if a borrower applies for a relief measure which is available only to corporates which have suspended operations or individuals who have lost employment. Another example is if the relief, such as a deferral of loan payments, is offered to all participants in certain industries. This circumstance may indicate that borrowers in that industry are exposed to a higher risk of business failure and, thus, a higher probability of default as a class. In combination with other reasonable and supportable information, this is more likely to result in the classification of the related loans and other exposures in this portfolio, or a portion of them, into stage 2. The assessment of whether there has been a significant increase in credit risk is made irrespective of the fact that a concession is imposed by laws or regulations. Entities are also expected to exercise judgement, in light of all facts and circumstances, including the effect of government support, to determine if the respective loans are credit-impaired and are therefore classified as stage 3.

Regulators stressed, in the context of the coronavirus pandemic, the need when assessing borrowers to differentiate a temporary liquidity need from a significant increase in credit risk. This meant that lenders distinguished between obligors whose long-term credit risk was unlikely to be significantly affected by the pandemic from those who might have been more permanently impacted.

Entities whose models include payment holidays or waiver of a covenant breach as automatic significant increase in credit risk triggers may need to include overlays to unwind the effects if they determine that the significant increase in credit risk trigger is not warranted. For retail loans, data will often not be available to determine whether a significant increase in credit risk has occurred for individual borrowers. For wholesale exposures, more information is generally available on individual obligors, although the significant increase in credit risk assessment will still be difficult. A lender may consider that borrowers in certain industries (e.g., airlines, tourism and hospitality) are exposed to a higher risk of business failure and, thus, an increased probability of default.

When it is not practical to determine significant increase in credit risk on an individual basis, a collective approach to staging is considered (see section 6.5 below). This will also be challenging. A possible method could be to transfer to stage 2 a portion of those customers who have been given a payment holiday or a waiver of a covenant breach, whose probability of default was already close to the level that would trigger a significant increase in credit risk. Any approach will require considerable judgement.

²² [IFRS 9 and covid-19: Accounting for expected credit losses applying IFRS 9 Financial Instruments in the light of current uncertainty resulting from the covid-19 pandemic](#), IASB, 27 March 2020. Available on the IFRS Foundation's website.

Where additional rounds of relief measures are extended to existing borrowers, the same considerations which were applicable to assessing the initial relief are also applicable in determining whether the additional relief constitutes a significant increase in credit risk. If the extension of the relief measures is offered only to selected borrowers (e.g., upon individual requests), it may be harder to conclude that a significant increase in credit risk has not occurred, as the need for additional relief may be in response to further deterioration in the borrower's financial position.

6.2.4 Illustrative Examples of factors or indicators when assessing significant increases in credit risk

The consideration of various factors or indicators when assessing significant increases in credit risk since initial recognition is illustrated in Illustration 6-2 and Illustration 6-3 below, which are based on Examples 1 and 2 in the Illustrative Examples to IFRS 9. [IFRS 9.IE Example 1, IFRS 9.IE7-IE11, IFRS 9.IE Example 2, IFRS 9.IE12-IE17].

Illustration 6-2: Significant increase in credit risk

Company Y has a funding structure that includes a senior secured loan facility with different tranches. The security on the loan affects the loss that would be realised if a default occurs, but does not affect the risk of a default occurring, so it is not considered when determining whether there has been a significant increase in credit risk since initial recognition as required by IFRS 9.5.5.3. Bank X provides a tranche of that loan facility to Company Y. At the time of origination of the loan by Bank X, although Company Y's leverage was relatively high compared with other issuers with similar credit risk, it was expected that Company Y would be able to meet the covenants for the life of the instrument. In addition, the generation of revenue and cash flow was expected to be stable in Company Y's industry over the term of the senior facility. However, there was some business risk related to the ability to grow gross margins within its existing businesses.

At initial recognition, because of the considerations outlined above, Bank X considers that despite the level of credit risk at initial recognition, the loan is not an originated credit-impaired loan because it does not meet the definition of a credit-impaired financial asset in Appendix A of IFRS 9.

Subsequent to initial recognition, macroeconomic changes have had a negative effect on total sales volume and Company Y has underperformed on its business plan for revenue generation and net cash flow generation. Although spending on inventory has increased, anticipated sales have not materialised. To increase liquidity, Company Y has drawn down more on a separate revolving credit facility, thereby increasing its leverage ratio. Consequently, Company Y is now close to breaching its covenants on the senior secured loan facility with Bank X.

Bank X makes an overall assessment of the credit risk on the loan to Company Y at the reporting date, by taking into consideration all reasonable and supportable information that is available without undue cost or effort and that is relevant for assessing the extent of the increase in credit risk since initial recognition. This may include factors such as:

- (a) Bank X's expectation that the deterioration in the macroeconomic environment may continue in the near future, which is expected to have a further negative impact on Company Y's ability to generate cash flows and to de-leverage.
- (b) Company Y is closer to breaching its covenants, which may result in a need to restructure the loan or reset the covenants.
- (c) Bank X's assessment that the trading prices for Company Y's bonds have decreased and that the credit margin on newly originated loans have increased reflecting the increase in credit risk, and that these changes are not explained by changes in the market environment (for example, benchmark interest rates have remained unchanged). A further comparison with the pricing of Company Y's peers shows that reductions in the price of Company Y's bonds and increases in credit margin on its loans have probably been caused by company-specific factors.
- (d) Bank X has reassessed its internal risk grading of the loan on the basis of the information that it has available to reflect the increase in credit risk.

Bank X determines that there has been a significant increase in credit risk since initial recognition of the loan in accordance with IFRS 9.5.5.3. Consequently, Bank X recognises lifetime expected credit losses on its senior secured loan to Company Y. Even if Bank X has not yet changed the internal risk grading of the loan it could still reach this conclusion - the absence or presence of a change in risk grading in itself is not determinative of whether credit risk has increased significantly since initial recognition.

Illustration 6-3: No significant increase in credit risk

Company C is the holding company of a group that operates in a cyclical production industry. Bank B provided a loan to Company C. At that time, the prospects for the industry were positive, because of expectations of further increases in global demand. However, input prices were volatile and given the point in the cycle, a potential decrease in sales was anticipated.

In addition, in the past Company C has been focused on external growth, acquiring majority stakes in companies in related sectors. As a result, the group structure is complex and has been subject to change, making it difficult for investors to analyse the expected performance of the group and to forecast the cash that will be available at the holding company level. Even though leverage is at a level that is considered acceptable by Company C's creditors at the time that Bank B originates the loan, its creditors are concerned about Company C's ability to refinance its debt because of the short remaining life until the maturity of the current financing. There is also concern about Company C's ability to continue to service interest using the dividends it receives from its operating subsidiaries.

At the time of the origination of the loan by Bank B, Company C's leverage was in line with that of other customers with similar credit risk and based on projections over the expected life of the loan, the available capacity (i.e., headroom) on its coverage ratios before triggering a default event, was high. Bank B applies its own internal rating methods to determine credit risk and allocates a specific internal rating score to its loans. Bank B's internal rating categories are based on historical, current and forward-looking information and reflect the credit risk for the tenor of the loans. On initial recognition, Bank B determines that the loan is subject to considerable credit risk, has speculative elements and that the uncertainties affecting Company C, including the group's uncertain prospects for cash generation, could lead to default. However, Bank B does not consider the loan to be originated credit-impaired.

Subsequent to initial recognition, Company C has announced that three of its five key subsidiaries had a significant reduction in sales volume because of deteriorated market conditions but sales volumes are expected to improve in line with the anticipated cycle for the industry in the following months. The sales of the other two subsidiaries were stable. Company C has also announced a corporate restructure to streamline its operating subsidiaries. This restructuring will increase the flexibility to refinance existing debt and the ability of the operating subsidiaries to pay dividends to Company C.

Despite the expected continuing deterioration in market conditions, Bank B determines, in accordance with IFRS 9.5.5.3, that there has not been a significant increase in the credit risk on the loan to Company C since initial recognition. This is demonstrated by factors that include:

- (a) Although current sales volumes have fallen, this was as anticipated by Bank B at initial recognition. Furthermore, sales volumes are expected to improve, in the following months.
- (b) Given the increased flexibility to refinance the existing debt at the operating subsidiary level and the increased availability of dividends to Company C, Bank B views the corporate restructure as being credit enhancing. This is despite some continued concern about the ability to refinance the existing debt at the holding company level.
- (c) Bank B's credit risk department, which monitors Company C, has determined that the latest developments are not significant enough to justify a change in its internal credit risk rating.

As a consequence, Bank B does not recognise a loss allowance at an amount equal to lifetime expected credit losses on the loan. However, it updates its measurement of the 12-month expected credit losses for the increased risk of a default occurring in the next 12 months and for current expectations of the credit losses that would arise if a default were to occur.

A numerical illustration of how a significant increase in credit risk might be assessed is shown in Illustration 6-4 below.

Illustration 6-4: Assessment of a significant increase in credit risk based on a probability of default approach

This example is based on the same loan presented in Illustration 5-1 in section 5.4.1 above.

On 31 December 20X1, Bank A originates a 10-year bullet loan with a gross carrying amount of CU1,000,000, interest being due at the end of each year. Based on statistical and qualitative information - including forward-looking, Bank A has estimated a BBB rating for the loan.

Based on this rating, Bank A has computed a probability of default term structure at origination. Bank A's probability of default term structure is estimated with the annual probability of default expected for each future period. The lifetime probability of default is the product of each marginal probability of default during the considered period:

$$\text{lifetime PD}_k = 1 - \prod_{i=1}^n (1 - \text{marginal PD}_i)$$

Finally, based on the marginal probability of default computed for each future period, Bank A is able to compute the forward lifetime probability of default as follows:

Year	Cumulative probability of default at origination	Marginal 12-month probability of default	Remaining lifetime probability of default	Remaining annualised lifetime probability of default
20X1				
20X2	0.17%	0.17%	4.50%	0.46%
20X3	0.49%	0.32%	4.34%	0.49%
20X4	0.86%	0.37%	4.03%	0.51%
20X5	1.38%	0.53%	3.67%	0.53%
20X6	1.84%	0.47%	3.16%	0.53%
20X7	2.37%	0.54%	2.71%	0.55%
20X8	2.85%	0.49%	2.18%	0.55%
20X9	3.30%	0.46%	1.70%	0.57%
20Y0	3.84%	0.56%	1.24%	0.62%
20Y1	4.50%	0.69%	0.69%	0.69%

For the first year, the remaining lifetime probability of default is the cumulative probability of default at origination. Then, after a year, it starts decreasing, considering that the remaining period is shorter. After 2 years it is 4.03% and after 3 years it is only 3.67%. At the end of the loan, the remaining lifetime probability of default ends up at 0%.

In common with many institutions, Bank A chooses to compare an annualised lifetime probability of default instead of a cumulative probability of default. This has the advantage that business lines and risk analysts can easily map an annualised probability of default onto a rating scale. It also enables an absolute change in annualised lifetime probability of default, e.g., 20 basis points, to be set as a 'filter', to exclude small changes in lifetime probability of default from being assessed as significant that are considered to be 'noise'. For this purpose, Bank A calculates an annualised probability of default, using the residual cumulative curve. The annualised lifetime probability of default (PD) is calculated as follows:

$$\text{Annualised lifetime PD}_k = 1 - (1 - \text{lifetime PD}_k)^{1/t}$$

When t = horizon of the lifetime probability of default expressed in years

20X3: No significant increase in credit risk: Stage 1

On 31 December 20X3 - 2 years after origination, Bank A updates the rating of its obligor. The rating is now BB+.

A new probability of default term structure is estimated based on this information:

Year	Cumulative lifetime probability of default
20X4	0.67%
20X5	1.53%
20X6	3.70%
20X7	5.58%
20X8	5.89%
20X9	6.51%
20Y0	7.45%
20Y1	8.70%
Remaining annualised lifetime probability of default	1.13%
Forecast at origination	0.51%
Increase (multiple)	2.20

In this example, Bank A uses a significant increase in credit risk threshold of a 2.5 multiple of probability of default. For simplicity we ignore any qualitative or other indicators that a bank might use to make this assessment.

Comparing the remaining annualised probability of default estimated at origination (0.51%) with the remaining annualised probability of default at the reporting date (1.13%), the increase is still only $\times 2.2$. We note that, had Bank A used a cumulative lifetime probability of default approach, it would compare 8.70% to 4.03%, which would also be a multiple of 2.2. The significant deterioration threshold set by Bank A is not met and therefore the loan remains in stage 1.

20X4: Significant increase in credit risk: Stage 2

On 31 December 20X4 - 3 years after origination, Bank A updates the rating of its obligor. Its rating is now BB-. Bank A updates its historical information for current economic conditions as well as reasonable and supportable forecasts of future economic conditions.

Year	Cumulative lifetime probability of default
20X5	1.40%
20X6	3.87%
20X7	8.82%
20X8	12.84%
20X9	16.04%
20Y0	18.98%
20Y1	21.60%
Remaining annualised lifetime probability of default	3.42%
Forecast at origination	0.53%
Increase (multiple)	6.41

As before, Bank A compares the remaining annualised probability of default estimated at origination (0.53%) with the remaining annualised probability of default at the reporting date (3.42%), an increase of 6.45 times the original probability of default. Had Bank A used a cumulative lifetime probability of default approach the comparison would be of 21.6% to 3.67%, a 6.41 fold increase. This time, the threshold of significant deterioration is met and the loan is moved to stage 2.

6.2.5 Use of behavioural factors

Frequently asked questions

Question 6-3: Whether an entity can use behavioural indicators of credit risk as a proxy for the assessment of significant increases in credit risk since initial recognition?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 16 September 2015 - Agenda paper no. 1)

At its meeting on 16 September 2015, the IFRS Transition Resource Group for Impairment of Financial Instruments (see section 1.4 above) discussed the following behavioural indicators of credit risk in determining whether there has been a significant increase in credit risk:

- Where a customer has made only the minimum monthly repayment for a specified number of months
- Where a customer has failed to make a payment on a loan with a different lender
- Where a customer has failed to make a specified number of minimum monthly repayments

The IFRS Transition Resource Group for Impairment of Financial Instruments members noted that:

- When assessing whether there has been a significant increase in credit risk, entities are required to consider a range of indicators rather than focussing on only one. Furthermore, while behavioural indicators have a role to play, the above behavioural indicators are often lagging indicators of increases in credit risk. Consequently, they should be considered in conjunction with other, more forward-looking information. In this regard, an entity must consider how to source and incorporate forward-looking information into the assessment of significant increases in credit risk and may need to do this on a collective basis if forward-looking information is not available at an individual financial instrument level.
- When considering the use of behavioural indicators, an entity should:
 - (a) Focus on identifying pre-delinquency behavioural indicators of increases in credit risk, e.g., increased utilisation rates or increased cash drawings on specific products.
 - (b) Only use indicators that are relevant to the risk of default occurring.
 - (c) Establish a link between the behavioural indicators of credit risk and changes in the risk of default occurring since initial recognition.
 - (d) Be mindful that while behavioural indicators are often predictive of defaults in the short term, they are often less predictive of defaults in the longer term, and, hence, might be lagging. Consequently, they potentially do not, on their own, signal significant increases in credit risk in a timely manner.
 - (e) Consider whether the use of behavioural indicators is appropriate for the type of product being assessed, e.g., if a loan has only back-ended payments, behavioural indicators based on timeliness of payment will not be appropriate.
- An entity is required to consider all information available without undue cost and effort and it should not be limited by the information that is available internally. For example, an entity should consider using third-party information from sources such as credit bureaus. However, information that is available to entities will vary across jurisdictions.
- When making the assessment of significant increases in credit risk, an entity should consider the possibility of segmenting the portfolio into groups of financial instruments with shared credit characteristics in such a way that similar indicators of credit risk could be used to identify increases in credit risk for specific sub-portfolios.
- It would not be appropriate to use the above behavioural indicators for the purposes of identifying low credit risk assets in accordance with IFRS 9.5.5.10 (see section 6.4.1 below), on the basis that such measures would not constitute a globally accepted definition of low credit risk as required by IFRS 9.

Other behavioural indicators, beyond those mentioned above, including items such as the level of cash advances, changes in expected payment patterns (e.g., moving from full payment to something less than full payment), and higher-than-expected utilisation of the facility, were raised at the meeting. Individually, these kinds of behaviours potentially are not determinative of a significant increase in credit risk but, when observed together, they may prove to be more indicative. By combining these indicators, an entity has the potential to transfer assets between stage 1 and stage 2 more meaningfully.

We also note that that one of the challenges with using behavioural information is that it depends on the starting point. That is, if the obligor's risk of default initially is consistent with a super-prime rating, the kind of deteriorating behaviour noted above would likely signal a significant shift. However, if the obligor originally had a sub-prime rating, then such behaviour might not indicate a significant increase in risk.

As noted by the IFRS Transition Resource Group for Impairment of Financial Instruments, while indicators that are more lagging may show a greater correlation with subsequent default, they are also likely to be less forward-looking. Although a probability of default approach may seem more sophisticated and forward-looking, it is still generally fed by behavioural information, even if it is combined, segmented and modelled in a more sophisticated way. If the only borrower-specific information is his behaviour, a forward-looking portfolio overlay will generally be required, whether a probability of default or a behavioural approach is used.

6.3 What is significant?

The assessment of whether credit risk has significantly increased depends, critically, on an interpretation of the word 'significant'. Some constituents who commented on the 2013 ED requested the IASB to quantify the term significant, however, the IASB decided not to do so, for the following reasons: [IFRS 9.BC5.171, IFRS 9.BC5.172]

- Specifying a fixed percentage change in the risk of default would require all entities to use the risk of default approach. As not all entities (apart from regulated financial institutions) use probability of defaults as an explicit input, this would have increased the costs and effort for those entities that do not use such an approach.
- Defining the amount of change in the risk of a default occurring would be arbitrary and this would depend on the type of products, maturities and initial credit risk.

IFRS 9 emphasises that the determination of the significance of the change in the risk of a default occurring depends on:

- The original credit risk at initial recognition: the same absolute change in probability of default for a financial instrument with a lower initial credit risk will be more significant than those with a higher initial credit risk (see section 6.1 above and Illustration 6-8 in section 6.4.5 below). [IFRS 9.B5.5.9].
- The expected life or term structure: the risk of a default occurring for financial instruments with similar credit risk increases the longer the expected life of the financial instruments. Due to the relationship between the expected life and the risk of a default occurring, an entity cannot simply compare the absolute risk of a default occurring over time. For example, if the risk of a default occurring for a financial instrument with an expected life of 10 years at initial recognition is the same after five years, then this indicates that the credit risk has increased. IFRS 9 also states that, for financial instruments that have significant payment obligations close to the maturity of the financial instrument (e.g., those where the principal is only repaid at maturity), the risk of a default occurring may not necessarily decrease as time passes. In such cases, an entity needs to consider other qualitative factors. We note, however, that while the risk of default may decrease less quickly for an instrument with payment obligations throughout its contractual life, normally, the risk of default will still decrease as maturity approaches. [IFRS 9.B5.5.10, IFRS 9.B5.5.11].

Some of these challenges are illustrated by examining the historical levels of default associated with the credit ratings of agencies, such as Standard & Poor's.

- It is apparent that the probability of defaults increase at a geometrical, rather than an arithmetic, rate as the credit ratings decline. Hence, the absolute increase in the probability of default between two relatively low risk credit ratings is considerably less than between two relatively higher risk ratings.
- The relative increase in probability of default between each of these ratings might be considered significant, since most involve a doubling or trebling of the probability of default. In contrast, because credit rating is an art rather than a science, the smaller changes in credit risk associated with the plus or minus notches in the grading system are less likely to be viewed as significant.
- In addition, as the time horizon increases, the probability of defaults also increase across all credit ratings (i.e., the probability of default increases with a longer maturity).

The majority of credit exposures that are assessed for significant credit deterioration will not have been rated by a credit rating agency. However, the same logic will apply when entities have developed their own probability of default models and are able to classify their exposure by probability of default levels.

The determination of what is significant will, for the larger banks, be influenced by the guidance issued by banking regulators (see section 7.1 below).

Given the exponential shape of the probability of default curve relative to ratings, some banks are considering that a bigger downgrade, as measured by the number of grades, would be significant for a higher quality loan than for one with a lower quality. The extent to which this is appropriate will depend on how the different grades map to probability of defaults. Also, the calibration of a significant deterioration has to take into account the fact that probability of default multiples for very good ratings only represent very small movements in absolute risk, whereas the same multiple applied to bad ratings can represent a significant change in the absolute amount of probability of default.

How we see it

Banks have varying views on how much of an increase in probability of default is significant. Also, while they may view a quantitative threshold, such as a doubling of probability of default, to be significant, many also require a minimum absolute probability of default increase, such as 50 basis points so as to avoid very high quality assets moving to stage 2 as a result of a very small change and to filter out 'noise'.

Banks have also introduced various metrics to assess the effect of different approaches to assess significant increase in credit risk and for management information. Examples include the volume of stage 2 assets compared to the total portfolio and compared to 12 months of lifetime expected losses, the volume of movement (back and forth) between stages 1 and 2, the amount of assets that jump directly from stage 1 to stage 3, the proportion of assets in stage 3 which went via stage 2, and how long assets were in stage 2 before moving to stage 3.

6.4 Operational simplifications

When assessing significant increases in credit risk, there are a number of operational simplifications available. These are discussed below.

6.4.1 Low credit risk operational simplification

IFRS 9 contains an important simplification that, if a financial instrument has a low credit risk, then an entity is allowed to assume at the reporting date that no significant increases in credit risk have occurred. The low credit risk concept was intended, by the IASB, to provide relief for entities from tracking changes in the credit risk of high-quality financial instruments. This simplification is optional and the low credit risk simplification can be elected on an instrument-by-instrument basis. [IFRS 9.BC5.184].

This is a change from the 2013 ED, in which a low risk exposure was deemed not to have suffered significant deterioration in credit risk. [IFRS 9.BC5.181, IFRS 9.BC5.182, IFRS 9.BC5.183]. The amendment to make the simplification optional was made in response to requests from constituents, including regulators. The Basel Committee guidance (see section 7.1 below) considers the use of the low credit risk simplification a low-quality implementation of the expected credit loss model and that the use of this exemption is limited, except for holdings in securities.

For low risk instruments for which the simplification is used, the entity would recognise an allowance based on 12-month expected credit losses. [IFRS 9.5.5.10]. However, if a financial instrument is not, or no longer, considered to have low credit risk at the reporting date, it does not follow that the entity is required to recognise lifetime expected credit losses. In such instances, the entity has to assess whether there has been a significant increase in credit risk since initial recognition which requires the recognition of lifetime expected credit losses. [IFRS 9.B5.5.24].

IFRS 9 lays out the criteria for determining when a financial instrument is considered to have low credit risk: [IFRS 9.B5.5.22, IFRS 9.B5.5.23]

Extract from IFRS 9

B5.5.22 The credit risk on a financial instrument is considered low for the purposes of paragraph 5.5.10, if the financial instrument has a low risk of default, the borrower has a strong capacity to meet its contractual cash flow obligations in the near term and adverse changes in economic and business conditions in the longer term may, but will not necessarily, reduce the ability of the borrower to fulfil its contractual cash flow obligations. Financial instruments are not considered to have low credit risk when they are regarded as having a low risk of loss simply because of the value of collateral and the financial instrument without that collateral would not be considered low credit risk. Financial instruments are also not considered to have low credit risk simply because they have a lower risk of default than the entity's other financial instruments or relative to the credit risk of the jurisdiction within which an entity operates.

B5.5.23 To determine whether a financial instrument has low credit risk, an entity may use its internal credit risk ratings or other methodologies that are consistent with a globally understood definition of low credit risk and that consider the risks and the type of financial instruments that are being assessed. An external rating of 'investment grade' is an example of a financial instrument that may be considered as having low credit risk. However, financial instruments are not required to be externally rated to be considered to have low credit risk. They should, however, be considered to have low credit risk from a market participant perspective taking into account all of the terms and conditions of the financial instrument.

The description of low credit risk is equivalent to investment grade quality assets, equivalent to a Standard and Poor's rating of BBB- or better, Moody's rating of Baa3 or better and Fitch's rating of BBB- or better. When applying the low credit risk simplification, financial instruments are not required to be externally rated. However, the IASB's intention was to use a globally comparable notion of low credit risk instead of a level of risk determined, for example, by an entity or jurisdiction's view of risk based on entity-specific or jurisdictional factors. [IFRS 9.BC5.188]. Therefore, an entity may use its internal credit ratings to assess what is low credit risk as long as this is consistent with the globally understood definition of low credit risk (i.e., investment grade) or the market's expectations of what is deemed to be low credit risk, taking into consideration the terms and conditions of the financial instruments being assessed. [IFRS 9.B5.5.23].

The Basel Committee guidance (see section 7.1 below) states that the investment grade category used by ratings agencies is not considered homogeneous enough to be automatically considered low credit risk, and internationally active and sophisticated banks are expected to rely primarily on their own credit assessments.

In practice, entities with internal credit ratings will attempt to map their internal rating to the external credit ratings and definitions, such as Standard & Poor's, Moody's and Fitch. The description of the credit quality ratings by these major rating agencies are illustrated below.²³

Figure 6-1: External credit ratings and definitions from the 3 major rating agencies

Standard & Poor's	Moody's	Fitch
Investment grade would usually refer to categories AAA to BBB (with BBB- being lowest investment grade considered by market participants).	Investment grade would usually refer to categories Aaa to Baa (with Baa3 being lowest investment grade considered by market participants).	Investment grade would usually refer to categories AAA to BBB (with BBB- being lowest investment grade considered by market participants).
BBB Adequate capacity to meet financial commitments, but more subject to adverse economic conditions .	Baa Obligations rated Baa are judged to be medium-grade and subject to moderate credit risk and as such may possess certain speculative characteristics.	BBB: Good credit quality Indicates that expectations of default risk are currently low . The capacity for payment of financial commitments is considered adequate but adverse business or economic conditions are more likely to impair this capacity.
The dividing line between investment grade and speculative grade		
BB Less vulnerable in the near-term but faces major on-going uncertainties to adverse business, financial and economic conditions.	Ba Obligations rated Ba are judged to be speculative and are subject to substantial credit risk.	BB: Speculative Indicates an elevated vulnerability to default risk, particularly in the event of adverse changes in business or economic conditions over time; however, business or financial flexibility exists which supports the servicing of financial commitments.

²³ [IASB Staff Paper 5B](#): Project: *Financial Instruments: Impairment*, Paper topic: *Operational simplifications - 30dpd and low credit risk*, IASB Meeting, 28 October - 1 November 2013. Available on the IFRS Foundation's website.

Examining the historical levels of default associated with the credit ratings of agencies such as Standard & Poor's, the probability of default of a BBB-rated loan is approximately treble that of one that is rated A. Hence, many entities would consider the increase in credit risk to be significant, if the low risk simplification is not used. The low credit risk simplification will not be relevant if an entity originates or purchases a financial instrument with a credit risk which is already non-investment grade. Similarly, this simplification will also have limited use when the financial instrument is originated or purchased with a credit quality that is marginally better than a non-investment grade (i.e., at the bottom of the investment grade rating), because any credit deterioration into the non-investment grade rating would require the entity to assess whether the increase in credit risk has been significant.

Partly because of the Basel Committee guidance, most sophisticated banks are applying the low risk simplification only to securities. Investors that hold externally rated debt instruments are more likely to rely on external rating agencies data and use the low credit risk simplification. However, some sophisticated banks do not to use it at all, preferring to use the same criteria as for other exposures (e.g., changes in the lifetime risk of default as the primary indicator followed by other risk metrics such as credit scores and ratings). It is also important to emphasise that although ratings are forward-looking, it is sometimes suggested that changes in credit ratings are not reflected in a timely matter. Therefore, entities may have to take account of expected change in ratings in assessing whether exposures are low risk.

The following example from IFRS 9 illustrates the application of the low credit risk simplification. [IFRS 9.IE Example 4, IFRS 9.IE24-IE28].

Illustration 6-5: Public investment-grade bond

Company A is a large listed national logistics company. The only debt in the capital structure is a five-year public bond with a restriction on further borrowing as the only bond covenant. Company A reports quarterly to its shareholders. Entity B is one of many investors in the bond. Entity B considers the bond to have low credit risk at initial recognition in accordance with IFRS 9.5.5.10. This is because the bond has a low risk of default and Company A is considered to have a strong capacity to meet its obligations in the near term. Entity B's expectations for the longer term are that adverse changes in economic and business conditions may, but will not necessarily, reduce Company A's ability to fulfil its obligations on the bond. In addition, at initial recognition the bond had an internal credit rating that is correlated to a global external credit rating of investment grade.

At the reporting date, Entity B's main credit risk concern is the continuing pressure on the total volume of sales that has caused Company A's operating cash flows to decrease.

Because Entity B relies only on quarterly public information and does not have access to private credit risk information (because it is a bond investor), its assessment of changes in credit risk is tied to public announcements and information, including updates on credit perspectives in press releases from rating agencies.

Entity B applies the low credit risk simplification in IFRS 9.5.5.10. Accordingly, at the reporting date, Entity B evaluates whether the bond is considered to have low credit risk using all reasonable and supportable information that is available without undue cost or effort. In making that evaluation, Entity B reassesses the internal credit rating of the bond and concludes that the bond is no longer equivalent to an investment grade rating because:

- (a) The latest quarterly report of Company A revealed a quarter-on-quarter decline in revenues of 20% and in operating profit by 12%.
- (b) Rating agencies have reacted negatively to a profit warning by Company A and put the credit rating under review for possible downgrade from investment grade to non-investment grade. However, at the reporting date the external credit risk rating was unchanged.
- (c) The bond price has also declined significantly, which has resulted in a higher yield to maturity. Entity B assesses that the bond prices have been declining as a result of increases in Company A's credit risk. This is because the market environment has not changed (for example, benchmark interest rates, liquidity, etc. are unchanged) and comparison with the bond prices of peers shows that the reductions are probably company specific (instead of being, for example, changes in benchmark interest rates that are not indicative of company-specific credit risk).

While Company A currently has the capacity to meet its commitments, the large uncertainties arising from its exposure to adverse business and economic conditions have increased the risk of a default occurring on the bond. As a result of the factors described above, Entity B determines that the bond does not have low credit risk at the reporting date. As a result, Entity B needs to determine whether the increase in credit risk since initial recognition has been significant. On the basis of its assessment, Company B determines that the credit risk has increased significantly since initial recognition and that a loss allowance at an amount equal to lifetime expected credit losses should be recognised in accordance with IFRS 9.5.5.3.

Some of the challenges in assessing whether there has been a significant increase in credit risk (including the use of the low credit risk simplification) and estimating the expected credit losses, are shown in the following Illustration. It shows different ways of identifying a significant change in credit quality and different input parameters for calculating expected credit losses for a European government bond, which result in very different outcomes and volatility of the IFRS 9 expected credit loss allowance. It is also stressed that the default rates provided by external rating agencies are historical information. Entities need to understand the sources of these historical default rates and update the data for current and forward-looking information (see section 5.9.3 above) when measuring expected credit losses or assessing credit deterioration.

Illustration 6-6: Use of credit ratings and/or credit default swap spreads to determine whether there have been significant increases in credit risk and to estimate expected credit losses

Introduction

A significant challenge in applying the IFRS 9 impairment requirements to quoted bonds is that the credit ratings assigned by agencies such as Standard & Poor's, and the historical experience of losses by rating grade, can differ significantly with the view of the market, as reflected in, for instance, credit default swap spreads and bond spreads.

To illustrate the challenges of applying IFRS 9 to debt securities, we have examined how the expected credit loss could be determined for a real bond issued by a European government on 16 September 2008 and due to mature in 2025. For three dates, we applied the IFRS 9 calculations to this bond, which is assumed to have been acquired at inception. In January 2009, the Standard & Poor's credit rating of the government was AA+, as at origination, but by January 2012, its rating was downgraded to A. The bond was further downgraded to BBB- in March 2014 before recovery to BBB in May 2014.

Three approaches

Shown below are three approaches:

- Approach 1: Use of S&P credit ratings both to determine whether the bond has significantly increased in credit risk and to estimate expected credit losses.
- Approach 2: Use of S&P credit ratings to determine whether the bond has significantly increased in credit risk and credit default swap spreads to estimate expected credit losses.
- Approach 3: Use of credit default swap spreads both to determine whether the bond has significantly increased in credit risk and to estimate expected credit losses.

Based on the historical corporate probability of defaults from each assessed S&P credit rating (approach 1) and based on the credit default swap spreads (approaches 2 and 3), the loan-loss percentages were calculated below. For the calculations, a loss given default of 60% was applied. (Because the loss given default represents a percentage of the present value of the gross carrying amount, this example does not illustrate the effect of the time value of money).

The percentage loss allowances were, as follows:

	Credit ratings	Historical 12-month probability of default based on ratings	12-month probability of default based on credit default swap spread	Lifetime probability of default based on credit default swap spread	Loss allowance (%)		
					Approach 1	Approach 2	Approach 3
1 January 2009	AA+	0.02%	0.44%	12.81%	-	-	-
31 January 2009	AA+	0.02%	1.84%	30.48%	0.01	1.10	18.29
31 January 2012	A	0.06%	4.96%	51.48%	0.04	2.98	30.89
31 March 2014	BBB-	0.31%	0.57%	23.01%	0.18	0.34	13.81

Approach 1

According to the credit ratings, the bond was investment grade throughout this period. Hence, using the low risk simplification, the loss allowance would have been based on 12-month expected credit losses. Using the corporate historical default rates implied by the credit ratings and an assumption of 60% loss given default to calculate the expected credit losses, the 12-month allowance would have increased from 0.01% on 31 January 2009 to 0.04% three years later, increasing to 0.18% by 31 March 2014. It is stressed that the historical default rates implied by credit ratings are historical rates for corporate debt and so they would not, without adjustment, satisfy the requirements of IFRS 9. IFRS 9 requires the calculation of expected credit losses, based on current conditions and forecasts of future conditions, to be based on reasonable and supportable information. This is likely to include market indicators such as credit default swap and bond spreads, as illustrated by Approach 2.

Approach 2

In contrast to Approach 1, using credit default swap spreads to calculate the expected credit losses and the same assumption of 60% loss given default to calculate the expected credit losses, the 12-month allowance would have increased from 1.1% on 31 January 2009 to 2.98% three years later, declining to 0.34% by 31 March 2014. The default rates implied by the credit default swaps are significantly higher than would have been expected given the ratings of these bonds. The loss allowances are, correspondingly, very much higher and very volatile. It might be argued that credit default swap spreads are too responsive to short term market sentiment to calculate long term expected credit losses, but it may appear difficult to find other reasonable and supportable information to adjust these rates so as to dampen the effects of market volatility.

Approach 3

Credit ratings are often viewed by the market as lagging indicators. For these bonds, the ratings are difficult to reconcile with the default probabilities as assessed by the markets. It might be argued that it is not sufficient to focus only on credit ratings when assessing whether assets are low risk since, according to credit default swap spreads, the bond was not low risk at any time in the period covered in this example, as it showed a significant increase in 1 year probability of default after inception (based on credit default swap spreads). The 1 year probability of defaults increased from 0.44% on issue to 1.84% by 31 January 2009. Assessing the bond as requiring a lifetime expected credit loss at all three dates, based on credit default swap spreads, would have given much higher loss allowances of 18.29%, 30.89% and 13.81%.

The counter-view might be that credit default swap spreads are too volatile to provide a sound basis for determining significant deterioration. Perhaps the best way to make the assessment of whether a bond has increased significantly in credit risk is to use more than one source of data and to take account of the qualitative indicators as described in IFRS 9.

Conclusion

The calculated expected credit loss figures differ significantly depending on the approach taken as to how to determine a significant change in credit quality and the parameters used for the calculation. Those based on credit default swap spreads are both large and very volatile, reflecting the investor uncertainty during the period, when the possibility of default depended more on the political will of the European Union to maintain the integrity of the Eurozone than the economic forecasts for the particular country. As a result, the disparity between the effect of the use of credit grades and credit default swaps is probably more marked than for most other security investments. Nevertheless, the same challenges will be found with other securities, albeit on a smaller scale.

6.4.2 Delinquency

As already described in section 6.2.2 above, IFRS 9 allows use of past due information to assess whether credit risk has increased significantly, if reasonable and supportable forward-looking information (either at an individual or a collective level) is not available without undue cost or effort. This is subject to the rebuttable presumption that there has been a significant increase in credit risk if contractual payments are more than 30 days past due. [IFRS 9.5.5.11]. Similar to the low credit risk simplification (see section 6.4.1 above), the Basel Committee guidance (see section 7.1 below) considers that sophisticated banks ought not to use days past due information as a primary indicator, because it is a lagging indicator, but only as a backstop measure alongside other, earlier indicators.

Most sophisticated banks are following this regulatory guidance. In addition, it is a useful measure of the effectiveness of more forward-looking primary criteria to monitor the frequency that assets reach 30 days past due without having already been transferred to stage 2.

6.4.3 12-month risk as an approximation for change in lifetime risk

In determining whether there has been a significant increase in credit risk, an entity must assess the change in the risk of default occurring over the expected life of the financial instrument. Despite this, IFRS 9 states that: "...changes in the risk of a default occurring over the next 12 months may be a reasonable approximation of the changes in the lifetime risk of a default occurring... unless circumstances indicate that a lifetime assessment is necessary". [IFRS 9.B5.5.13].

The IASB observed in its Basis for Conclusions that changes in the risk of a default occurring within the next 12 months generally should be a reasonable approximation of changes in the risk of a default occurring over the remaining life of a financial instrument and thus would not be inconsistent with the requirements. Also, some entities use a 12-month probability of default measure for prudential regulatory requirements and these entities can continue to use their existing systems and methodologies as a starting point for determining significant increases in credit risk, thus reducing the costs of implementation. [IFRS 9.BC5.178].

However, for some financial instruments, or in some circumstances, the use of changes in the risk of default occurring over the next 12 months may not be appropriate to determine whether lifetime expected credit losses should be recognised. For a financial instrument with a maturity longer than 12 months, IFRS 9 gives the following examples: [IFRS 9.B5.5.14]

Extract from IFRS 9

B5.5.14 However, for some financial instruments, or in some circumstances, it may not be appropriate to use changes in the risk of a default occurring over the next 12 months to determine whether lifetime expected credit losses should be recognised. For example, the change in the risk of a default occurring in the next 12 months may not be a suitable basis for determining whether credit risk has increased on a financial instrument with a maturity of more than 12 months when:

- (a) the financial instrument only has significant payment obligations beyond the next 12 months;
- (b) changes in relevant macroeconomic or other credit-related factors occur that are not adequately reflected in the risk of a default occurring in the next 12 months; or
- (c) changes in credit-related factors only have an impact on the credit risk of the financial instrument (or have a more pronounced effect) beyond 12 months.

Frequently asked questions

Question 6-4: Whether, and if so to what extent, an entity would be required to perform a review to determine whether circumstances still support the use of changes in the 12-month risk of a default occurring as an approximation of changes in the lifetime risk of default occurring?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 16 September 2015 - Agenda paper no. 2)

At its meeting on 16 September 2015 (see section 1.4 above), the IFRS Transition Resource Group for Impairment of Financial Instruments members discussed the use of changes in 12-month risk of default as a surrogate for changes in lifetime risk and commented as follows:

- An entity would be expected to complete a robust analysis up front in order to support the conclusion that changes in the 12-month risk of a default occurring was a reasonable approximation for the assessment of changes in the lifetime risk of default occurring.
- The level of initial analysis required would depend on the specific type of financial instrument being considered. Consequently, in some cases, a qualitative analysis would suffice whereas in less clear-cut cases, a quantitative analysis may be necessary. Also, it may be appropriate to segregate portfolios (e.g., by maturity) in order to facilitate the analysis for groups of similar financial instruments.
- An entity would need to be satisfied on an ongoing basis that the use of changes in the 12-month risk of a default occurring continued to be a reasonable approximation for changes in the lifetime risk of a default occurring.

At the meeting, the IFRS Transition Resource Group for Impairment of Financial Instruments members also discussed:

- The appropriate type of review that should be undertaken on an ongoing basis. While a quantitative review would not necessarily be required, it would depend on the specific facts and circumstances. One way of approaching an ongoing review would be as follows:
 - (a) Identify the key factors that would affect the appropriateness of using changes in the 12-month risk of a default occurring as an approximation of changes in the lifetime risk of default occurring.
 - (b) Monitor these factors on an ongoing basis as part of a qualitative review of circumstances.
 - (c) Consider whether any changes in those factors indicated that changes in the 12-month risk of a default occurring was no longer an appropriate proxy for changes in a lifetime risk of default occurring.
- If it were determined that changes in the 12-month risk of a default occurring were no longer a reasonable approximation for the assessment of changes in the lifetime risk of a default occurring, an entity would be required to determine an appropriate approach to capture changes in the lifetime risk of a default occurring.
- It is important to emphasise that the guidance which permits an entity to use changes in the 12-month risk of a default as an approximation for the lifetime risk of default, is only relevant for the assessment of significant increases in credit risk and does not relate to the measurement of expected credit losses. When an entity is required to measure lifetime expected credit losses, that measurement must always reflect the lifetime risk of a default occurring.
- IFRS 9 does not prescribe how an entity should determine whether the use of changes in the 12-month risk of a default was an appropriate proxy for assessing changes in the lifetime risk of a default. However, it was noted that entities are required to disclose how they make the assessment of significant increases in credit risk, in accordance with IFRS 7.

How we see it

Most sophisticated banks are using the lifetime risk of default (or an annualised equivalent) rather than the 12-month risk of default or the Basel risk of default for assessing whether there has been a significant increase in credit risk. Movements in a 12-month risk of default are, for most products and conditions, strongly correlated with movements in the lifetime risk. However, these banks appreciate that 12-month probability of defaults may need to be adjusted or calibrated to reflect the longer-term macroeconomic outlook. Also, there are products such as interest-only mortgages and those with an introductory period in which no repayments are required, where additional procedures may need to be implemented in order to ensure that they are transferred to stage 2 appropriately.

6.4.4 Assessment at the counterparty level

As indicated by Example 7 in the Illustrative Examples to IFRS 9, assessment of significant deterioration in credit risk can be made at the level of the counterparty rather than the individual financial instrument. Such assessment at the counterparty level is only allowed if the outcome would not be different to the outcome if the financial instruments had been individually assessed. [IFRS 9.BC5.168]. In certain circumstances, assessment at the counterparty level would not be consistent with the impairment requirements. Both these situations are shown in the Illustration below, based on Example 7 in the Illustrative Examples to IFRS 9. [IFRS 9.IE Example 7, IFRS 9.IE43-IE47].

Illustration 6-7: Counterparty assessment of credit risk

Scenario 1

In 20X1 Bank A granted a loan of CU10,000 with a contractual term of 15 years to Company Q when the company had an internal credit risk rating of 4 on a scale of 1 (lowest credit risk) to 10 (highest credit risk). The risk of a default occurring increases exponentially as the credit risk rating deteriorates so, for example, the difference between credit risk rating grades 1 and 2 is smaller than the difference between credit risk rating grades 2 and 3. In 20X6, when Company Q had an internal credit risk rating of 6, Bank A issued another loan to Company Q for CU5,000 with a contractual term of 10 years. In 20X8 Company Q fails to retain its contract with a major customer and correspondingly experiences a large decline in its revenue. Bank A considers that as a result of losing the contract, Company Q will have a significantly reduced ability to meet its loan obligations and changes its internal credit risk rating to 8.

Bank A assesses credit risk on a counterparty level for credit risk management purposes and determines that the increase in Company Q's credit risk is significant. Although Bank A did not perform an individual assessment of changes in the credit risk on each loan since its initial recognition, assessing the credit risk on a counterparty level and recognising lifetime expected credit losses on all loans granted to Company Q, meets the objective of the impairment requirements as stated in IFRS 9.5.5.4. This is because, even since the most recent loan was originated (in 20X6) when Company Q had the highest credit risk at loan origination, its credit risk has increased significantly. The counterparty assessment would therefore achieve the same result as assessing the change in credit risk for each loan individually.

Scenario 2

Bank A granted a loan of CU150,000 with a contractual term of 20 years to Company X in 20X1 when the company had an internal credit risk rating of 4. During 20X6 economic conditions deteriorate and demand for Company X's products has declined significantly. As a result of the reduced cash flows from lower sales, Company X could not make full payment of its loan instalment to Bank A. Bank A re-assesses Company X's internal credit risk rating, and determines it to be 7 at the reporting date. Bank A considered the change in credit risk on the loan, including considering the change in the internal credit risk rating, and determines that there has been a significant increase in credit risk and recognises lifetime expected credit losses on the loan of CU150,000.

Despite the recent downgrade of the internal credit risk rating, Bank A grants another loan of CU50,000 to Company X in 20X7 with a contractual term of 5 years, taking into consideration the higher credit risk at that date.

The fact that Company X's credit risk (assessed on a counterparty basis) has previously been assessed to have increased significantly, does not result in lifetime expected credit losses being recognised on the new loan. This is because the credit risk on the new loan has not increased significantly since the loan was initially recognised. If Bank A only assessed credit risk on a counterparty level, without considering whether the conclusion about changes in credit risk applies to all individual financial instruments provided to the same customer, the objective in IFRS 9.5.5.4 would not be met.

How we see it

Most banks manage their credit exposures on a counterparty basis and are keen to use their existing risk management processes to calculate the IFRS 9 expected credit losses where they can. This is particularly the case for those banks who seek to use processes such as the use of watch lists to make the assessment of whether there has been a significant increase in credit risk. However, IFRS 9 only allows use of a counterparty basis when it can be demonstrated that it would make no difference from making the assessment at an individual instrument level. It may be necessary for these banks to add procedures to track increase in the risk of default at the instrument level in order to comply with IFRS 9.

6.4.5 Determining maximum initial credit risk for a portfolio

The IFRS 9 credit risk assessment that determines whether a financial instrument attracts a lifetime expected credit loss allowance, or only a 12-month expected credit loss allowance, is based on whether there has been a relative increase in credit risk. One of the challenges identified by some constituents in responding to the 2013 ED was that many credit risk systems monitor absolute levels of risk, without tracking the history of individual loans (see section 6.1 above). To help address this concern IFRS 9 contains an approach that turns a relative system into an absolute one, by segmenting the portfolio sufficiently by loan quality at origination.

As indicated by Example 6 in the Illustrative Examples to IFRS 9 on which Illustration 6-8 below is based, an entity can determine the maximum initial credit risk accepted for portfolios with similar credit risks on initial recognition. [IFRS 9.IE Example 6, IFRS 9.IE40, IFRS 9.IE41, IFRS 9.IE42]. Thereby, an entity may be able to establish an absolute threshold for recognising lifetime expected credit losses.

Illustration 6-8: Comparison to maximum initial credit risk

Bank A has two portfolios of automobile loans with similar terms and conditions in Region W. Bank A's policy on financing decisions for each loan is based on an internal credit rating system that considers a customer's credit history, payment behaviour on other products with Bank A and other factors, and assigns an internal credit risk rating from 1 (lowest credit risk) to 10 (highest credit risk) to each loan on origination. The risk of a default occurring increases exponentially as the credit risk rating deteriorates so, for example, the difference between credit risk rating grades 1 and 2 is smaller than the difference between credit risk rating grades 2 and 3. Loans in Portfolio 1 were only offered to existing customers with a similar internal credit risk rating and at initial recognition all loans were rated 3 or 4 on the internal rating scale. Bank A determines that the maximum initial credit risk rating at initial recognition it would accept for Portfolio 1 is an internal rating of 4. Loans in Portfolio 2 were offered to customers that responded to an advertisement for automobile loans and the internal credit risk ratings of these customers range between 4 and 7 on the internal rating scale. Bank A never originates an automobile loan with an internal credit risk rating worse than 7 (i.e., with an internal rating of 8-10).

For the purposes of assessing whether there have been significant increases in credit risk, Bank A determines that all loans in Portfolio 1 had a similar initial credit risk. It determines that given the risk of default reflected in its internal risk rating grades, a change in internal rating from 3 to 4 would not represent a significant increase in credit risk but that there has been a significant increase in credit risk on any loan in this portfolio that has an internal rating worse than 5. This means that Bank A does not have to know the initial credit rating of each loan in the portfolio to assess the change in credit risk since initial recognition. It only has to determine whether the credit risk is worse than 5 at the reporting date to determine whether lifetime expected credit losses should be recognised in accordance with IFRS 9.5.5.3.

However, determining the maximum initial credit risk accepted at initial recognition for Portfolio 2 at an internal credit risk rating of 7, would not meet the objective of the requirements as stated in IFRS 9.5.5.4. This is because Bank A determines that significant increases in credit risk arise not only when credit risk increases above the level at which an entity would originate new financial assets (i.e., when the internal rating is worse than 7). Although Bank A never originates an automobile loan with an internal credit rating worse than 7, the initial credit risk on loans in Portfolio 2 is not of sufficiently similar credit risk at initial recognition to apply the approach used for Portfolio 1. This means that Bank A cannot simply compare the credit risk at the reporting date with the lowest credit quality at initial recognition (for example, by comparing the internal credit risk rating of loans in Portfolio 2 with an internal credit risk rating of 7) to determine whether credit risk has increased significantly because the initial credit quality of loans in the portfolio is too diverse. For example, if a loan initially had a credit risk rating of 4 the credit risk on the loan may have increased significantly if its internal credit risk rating changes to 6.

Frequently asked questions

Question 6-5: How an entity should determine whether there has been a significant increase in credit risk for a portfolio of loans advanced to customers across broad credit quality bands with identical pricing and contractual terms, for example, retail loans?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 16 September 2015 - Agenda paper no. 1)

At the IFRS Transition Resource Group for Impairment of Financial Instruments meeting on 16 September 2015 (see section 1.4 above), the question raised was influenced by the operational simplification described above, which allows an entity to assess if there has been a significant increase in credit risk by determining the maximum initial credit risk accepted for portfolios with similar credit risks on original recognition, and by reviewing which exposures now exceed this limit. The IFRS Transition Resource Group for Impairment of Financial Instruments discussed an example of a retail loan portfolio (Portfolio A) comprising customers who had been assigned initial credit grades between 1 and 5 (based on a 10 grade rating scale where 1 is the highest credit quality) and had been issued loans with the same contractual terms and pricing. The question was whether it would be appropriate to make the determination of significant increases in credit risk by using a single threshold approach such as that outlined for Portfolio 1 in Illustrative Example 6 of IFRS 9, on the basis that the exposures in Portfolio A could be considered to have a similar initial credit risk, or whether there were other more appropriate approaches such as, for example, defining a significant increase in credit risk as a specific number of notch increases in credit grade.

The IFRS Transition Resource Group for Impairment of Financial Instruments members observed that:

- When assessing whether there has been a significant increase in credit risk, it would not be appropriate for the entity to consider only factors such as pricing and contractual terms. In this regard, while the concept of economic loss was considered in developing the IFRS 9 model, the standard requires an assessment of changes in credit risk based on a wide range of factors including internal and external indicators of credit risk, changes to contractual terms, actual and expected performance/behaviours and forecasts of future conditions.
- Credit grading systems were not necessarily designed with the requirements of IFRS 9 in mind, and thus it should not be assumed that they will always be an appropriate means of identifying significant increases in credit risk. The appropriateness of using internal credit grading systems as a means of assessing changes in credit risk since initial recognition depends on whether the credit grades are reviewed with sufficient frequency, include all reasonable and supportable information and reflect the risk of default over the expected life of the financial instrument. As credit grading systems vary, care needs to be taken when referring to movements in credit grades and how this reflects an increased risk of default occurring. In addition, the assessment of whether a change in credit risk grade represents a significant increase in credit risk in accordance with IFRS 9 depends on the initial credit risk of the financial instrument being assessed. Because the relationship between credit grades and changes in the risk of default occurring differs between credit grading systems (e.g., in some cases the changes in the risk of a default occurring will increase exponentially between grades whereas in others it will not), this requires particular consideration.
- Consequently, the impairment model is based on an assessment of changes in credit risk since initial recognition, rather than the identification of a specific level of credit risk at the reporting date and a smaller absolute change in the risk of default occurring will be more significant for an asset that is of high quality on initial recognition than for one that is of low quality.
- In Example 6 in the Illustrative Examples to IFRS 9, the assessment of significant increases in credit risk of Portfolio 1 was made using a form of absolute approach. However, it was pointed out that this approach was still consistent with the objective of identifying significant increases in credit risk since initial recognition. In particular, only loans with an initial credit grade of 3 or 4 were included in Portfolio 1 and furthermore, the entity had concluded that a movement from credit grade 3 to 4 did not represent a significant increase in credit risk. Consequently, using a single threshold of credit grade 5 as a means of identifying a significant increase in credit risk since initial recognition served to capture changes in credit risk in a manner that achieved the objective of the impairment requirements.
- In contrast, in the fact pattern discussed, Portfolio A contained loans with initial credit grades ranging between 1 and 5. Questions were raised as to whether such a broad range of credit grades could be considered to represent a similar initial credit risk and the IFRS Transition Resource Group for Impairment of Financial Instruments members noted that in order to conclude that the assessment could be based on whether loans had a credit rating worse than 5, the entity would need to have determined that movements between credit grades 1 and 5 did not represent a significant increase in credit risk.
- Information available at an individual financial instrument level and/or built into a credit risk grading system could potentially not incorporate forward-looking information as required by IFRS 9. Consequently, the assessment of significant increases in credit risk may need to be supplemented by a collective assessment to capture forward-looking information. However, a collective assessment should not obscure significant increases in credit risk at an individual financial instrument level. In this regard, portfolio segmentation is important and entities should ensure that sub-portfolios are not defined too widely.

6.5 Collective assessment

Banks may have hundreds of thousands, or even millions, of small exposures to retail customers and small businesses. Much of the information available to monitor them is based on whether payments are past due and behavioural information that is mostly historical rather than forward-looking. As a result, such exposures tend to be managed on an aggregated basis, combining past due and behavioural data with historical statistical experience and sometimes macroeconomic indicators, such as interest rates and unemployment levels, that tend to correlate with future defaults. Also, even when exposures are managed on an individual basis, as is the case for most commercial loans, the information used to manage them could potentially not be sufficiently forward-looking to comply with IFRS 9.

To address these concerns, IFRS 9 introduced the idea of making a collective assessment for financial assets, to determine if there has been a significant increase in credit risk, if an entity cannot make the assessment adequately on an individual instrument level. This exercise must consider comprehensive information that incorporates not only past due data but other relevant credit information, such as forward-looking macroeconomic information. The objective is to approximate the result of using comprehensive credit information that incorporates forward-looking information at an individual instrument level.

[IFRS 9.B5.5.4]. Hence, even if a financial asset is normally managed on an individual basis, it is also assessed collectively (i.e., based on macroeconomic indicators), if the entity does not have sufficient forward-looking information at the individual level to make the determination. The way that this might work would be to assess an asset collectively for impairment if it has already been assessed individually and found not to be impaired.

How we see it

Some kind of collective adjustment or overlay will be needed for many retail lending portfolios, given that most customer-specific information will not be forward-looking. In contrast, for commercial loans, the lender will typically have access to much more information and a forward-looking approach may already have been built into loan grading systems. Nevertheless, some banks have introduced an additional overlay for commercial loans so as to be more responsive to emerging macroeconomic and other risk developments.

Other banks use their existing watch list approaches to supplement their credit grading system when assessing whether there has been a significant increase in credit risk. This is because watch list systems can be more reactive to changing circumstances than formal credit gradings. Any one bank is likely to employ a variety of methods, depending on its products, systems and data.

In abnormal circumstances, for example during the coronavirus pandemic (see section 7.8 below), it may take time for an entity to detect actual changes in risk indicators for a specific counterparty. In order to accelerate the reflection of such changes in credit quality not yet detected at an individual level, it may be appropriate to adjust ratings and the probability of default on a collective basis, considering risk characteristics such as the industry or geographical location of the borrowers. For example, a supplier of products or services to the airline industry would likely consider, in the context of the coronavirus pandemic, that the probability of default (or loss rates, if a provision matrix approach is used) of its customers has increased irrespective of specific events identified at the level of individual counterparties.

It is worth noting that the language on when a collective approach is required is not entirely consistent within the standard. Paragraph B5.5.1 of IFRS 9 states that “it *may be* necessary to perform the assessment of significant increases in credit risk on a collective basis” (emphasis added), which is consistent with the requirement in IFRS 9.5.5.11, that an entity cannot rely solely on past due information if reasonable and supportable forward-looking information is available without undue cost or effort. However, IFRS 9.B5.5.4 states that “In some circumstances an entity does not have reasonable and supportable information that is available without undue cost or effort to measure lifetime expected credit losses on an individual instrument basis. In that case, lifetime expected credit losses *shall* be recognised on a collective basis...” (emphasis added). Banking regulators will probably ensure that this ‘shall be’ wording will be applied, at least for more sophisticated banks (see section 1.5 above and section 7.1 below). This raises a second concern: once significant deterioration has been identified for a portfolio, whether the entire portfolio would have to be measured using lifetime expected credit losses. This outcome would result in sudden, massive increases in provisions as soon as conditions begin to decline. Consequently, the Board, in finalising IFRS 9, set out examples of possible methods, using which only a segment or portion of the portfolio would be changed to lifetime expected credit losses.

Example 5 in the Illustrative Examples to IFRS 9 illustrates how an entity may assess whether its individual assessment is complemented with a collective one whenever the information at individual level is not sufficiently comprehensive and up-to-date. The following Illustrations have been adapted from that guidance.

6.5.1 Example of individual assessment of changes in credit risk

First, as a benchmark, Scenario 1 (an individual assessment) illustrates a situation where a bank has sufficient information at individual exposure level to identify a significant deterioration of credit quality.

Illustration 6-9: Individual assessment in relation to responsiveness to changes in credit risk

The bank assesses each of its mortgage loans on a monthly basis by means of an automated behavioural scoring process based on current and historical past due statuses, levels of customer indebtedness, loan-to-value measures, customer behaviour on other financial instruments with the bank, the loan size and the time since the origination of the loan. It is said that historical data indicates a strong correlation between the value of residential property and the default rates for mortgages.

The bank updates the loan-to-value measures on a regular basis through an automated process that re-estimates property values using recent sales in each post code area and reasonable and supportable forward-looking information that is available without undue cost or effort. Therefore, an increased risk of a default occurring due to an expected decline in residential property value adjusts the behavioural scores and the bank is therefore able to identify significant increases in credit risk on individual customers before a mortgage becomes past due if there has been a deterioration in the behavioural score.

The example concludes that if the bank is unable to update behavioural scores to reflect the expected declines in property prices, it would use reasonable and supportable information that is available without undue cost or effort to undertake a collective assessment to determine the loans on which there has been a significant increase in credit risk since initial recognition and recognize lifetime expected credit losses for those loans.

It is noted that, in this example, the main source of forward-looking information is expected future property prices. No account would appear to be taken of other economic data such as future levels of employment or interest rates. We assume that the Board took this approach to make the example simple, but as written, it implies that future property prices are considered to provide a sufficiently good guide to future defaults that it is not necessary to take account of other data as well.

6.5.2 Basis of aggregation for collective assessment

Next, IFRS 9 sets out how financial instruments may be grouped together in order to determine whether there has been a significant increase in credit risk. Any instruments assessed collectively must possess shared credit risk characteristics. It is not permitted to aggregate exposures that have different risks and, in so doing, obscure significant increases in risk that may arise on a sub-set of the portfolio. IFRS 9 provides some examples of shared credit risk characteristics: [IFRS 9.B5.5.5]

Extract from IFRS 9

B5.5.5 For the purpose of determining significant increases in credit risk and recognising a loss allowance on a collective basis, an entity can group financial instruments on the basis of shared credit risk characteristics with the objective of facilitating an analysis that is designed to enable significant increases in credit risk to be identified on a timely basis. The entity should not obscure this information by grouping financial instruments with different risk characteristics. Examples of shared credit risk characteristics may include, but are not limited to, the:

- (a) instrument type;
- (b) credit risk ratings;
- (c) collateral type;
- (d) date of initial recognition;
- (e) remaining term to maturity;
- (f) industry;
- (g) geographical location of the borrower; and
- (h) the value of collateral relative to the financial asset if it has an impact on the probability of a default occurring (for example, non-recourse loans in some jurisdictions or loan-to-value ratios).

IFRS 9 also states that the basis of aggregation of financial instruments to assess whether there have been changes in credit risk on a collective basis may have to change over time, as new information on groups of, or individual, financial instruments becomes available. [IFRS 9.B5.5.6].

We make the following observations:

- As has been stressed earlier, the assessment of significant deterioration is intended to reflect the risk of default, not the risk of loss, hence collateral is normally ignored for the assessment. IFRS 9 nonetheless explains that the value of collateral relative to the financial asset would be relevant to the collective assessment if it has an impact on the risk of a default occurring. It cites, as an example, non-recourse loans in certain jurisdictions. The question of when such an arrangement would always meet the IFRS 9 classification and measurement characteristics of the Asset test is beyond the scope of this chapter. Loan-to-value or a house price index may be a useful indicator of significant collective deterioration in a wider range of circumstances than just where the loans are non-recourse. First, house prices are themselves a useful barometer of the economy and so higher loan-to-values and lower indices correlate with declining economic conditions. Second, loans that were originally advanced at higher loan-to-value may reflect more aggressive lending practices, with the consequence that such loans may exhibit a higher probability of default if economic conditions decline. Third, a borrower in trouble with a lower loan-to-value will likely sell his house to redeem the mortgage rather than defaulting on the mortgage (and, conversely, a borrower with a high loan-to-value will have less incentive not to default).
- By date of original recognition, we assume that the Board did not intend that loans are assessed in separate groups for each year of origination, but that vintages may be aggregated into groups that share similar credit risk characteristics. Loan products and lending practices, including the extent of due diligence, and key ratios, such as the loan-to-value and loan to income, change over time, often reflecting the economic conditions at the time of origination. The consequence is that loans from particular years are inherently riskier than others. For some banks, this might mean isolating those loans advanced just prior to the financial crisis from those originated earlier or in the subsequent, more careful lending environment. Also, there is a phenomenon termed seasoning, which describes how loans that have been serviced adequately for a number of years, over a business cycle, are statistically less likely to default in future, suggesting that older loans are assessed separately.
- Although the examples in IFRS 9 refer to regions, as the geographical location of borrowers, the groupings could be much larger, such as by country, or much smaller, if there are particular issues associated with particular towns. Hence the choice of geographical groupings will depend very much on the environment in which a bank operates.
- Other ways that loans might be grouped according to shared credit risk characteristics could include by credit score, by payment history, whether previously restructured or subject to forbearance but subsequently restored to a 12-month expected credit loss allowance, and manner of employment (as featured in Illustrative Example 5 in the Illustrative Examples to IFRS 9 under the bottom-up assessment discussed in Illustration 6-10 in section 6.5.3 below).
- The requirement that financial instruments that are assessed together must share similar credit risk characteristics means that a bank may have a substantial number of portfolios. Even a relatively small bank might have six different products (taking into account terms to maturity and types of collateral), three regions and three different vintage groups which, multiplied out, would give 54 different assessment groups. A larger global bank might need to monitor many more different portfolios. However, a balance will need to be struck between ensuring that portfolios are small enough to have sufficient homogeneity and yet not so small that there is too little historical data for losses to be reliably estimated.

How we see it

The requirement that groupings may have to be amended over time to assess changes in credit risk, means that there must be processes put in place to reassess whether loans continue to share similar credit risk characteristics. Yet, in practice, there will need to be a sufficient level of stability in the construction of portfolios to allow enough historical data to be gathered for reliable estimation of losses.

Finally, IFRS 9.B5.5.6 adds that, “if an entity is not able to group financial instruments for which the credit risk is considered to have increased significantly since initial recognition based on shared credit risk characteristics, the entity should recognise lifetime expected credit losses on a portion of the financial assets for which credit risk is deemed to have increased significantly”.

As clarified by the IASB in its webcast on forward-looking information on 25 July 2016, it is possible that a bank is aware of differences in sensitivities of credit risk to a change in a particular parameter but is unable to group the assets on the basis of such sensitivity. In such instances, the bank may determine that the expected forward-looking scenario would result in significant increases in credit risk for a certain proportion of its portfolio.

6.5.3 Example of collective assessment ('bottom up' and 'top down' approach)

The main standard does not amplify how a collective assessment would be made but Example 5 in the Illustrative Examples to IFRS 9 provides two scenarios that explore the approach. [IFRS 9.IE Example 5, IFRS 9.IE29-IE39].

Illustration 6-10: Collective assessment in relation to responsiveness to changes in credit risk ('bottom up' approach)

Region Two of Illustrative Example 5 in the Illustrative Examples to IFRS 9 introduces the so-called bottom-up method. It deals with a mining community within a region that faces unemployment risk due to a decline in coal exports and, consequently, anticipated future mine closures. Although most of the loans are not yet 30 days past due and, further, the borrowers are not yet unemployed, the bank re-segments its mortgage portfolio so as to separate loans to customers employed in the mining industry (based on information in the original mortgage application form).

For these loans (plus any others that are more than 30 days past due), Bank ABC recognises lifetime expected credit losses, while it continues to recognise 12-month expected credit losses for the other mortgage loans in the region. Any new loans to borrowers who rely on the coal industry would also attract only a 12-month allowance, until they also demonstrate a significant increase in credit risk.

The bottom-up method is described as an example of how to assess credit deterioration by using information that is more forward-looking than past due status. But this example also illustrates that collectively assessed groups may need to change over time, to ensure that they share similar credit risk characteristics. Once the coal mining industry begins to decline, those loans connected with it would no longer share the same risk characteristics as other loans to borrowers in the region, and so would need to be assessed separately. We also note that this example assumes that macroeconomic factors can be linked to the expected credit losses of a very specific portfolio. Further, in practice, most banks do not have the data to achieve this level of segmentation.

As already described above (possible criteria for grouping of financial assets with similar credit risk characteristics), the bottom-up approach could be applied to sub-portfolios differentiated by type of instrument, risk rating, type of collateral, date of initial recognition, remaining term to maturity, industry, geographical location of the borrower, or the loan-to-value ratio. A good example of this approach might be for exposures to borrowers that are expected to suffer major economic difficulties due to war or political upheaval, or borrowers with the weakest credit scores, who are expected to be more sensitive to a change in a relevant macroeconomic factor. In addition, as underwriting standards may vary or change, the portfolio might be sub-divided so as to reflect this. Note that the coal mines closures are, as yet, only anticipated, hence this example helps show how IFRS 9 is intended to be forward looking. The need to look forward is also illustrated in the next example.

Illustration 6-11: Collective assessment in relation to responsiveness to changes in credit risk ('top down' approach)

For Region Three of Illustrative Example 5 in the Illustrative Examples to IFRS 9, Bank ABC anticipates an increase in defaults following an expected rise in interest rates. Historically, an increase in interest rates has been a lead indicator of future defaults on floating-rate mortgages in the region. The bank regards the portfolio of variable rate mortgage loans in that region to be homogenous and it is incapable of identifying particular sub-portfolios on the basis of shared credit risk characteristics. Hence, it uses what is described as a top-down method.

Based on historical data, the bank estimates that a 200 basis points rise in interest rates will cause a significant increase in credit risk on 20% of the mortgages. As a result, presumably because the bank expects a 200 basis points rise in rates, it recognises lifetime expected credit losses on 20% of the portfolio (along with those loans that are more than 30 days past due) and 12-month expected credit losses on the remainder of mortgages in the region.

The challenge posed by the top-down method is how to calculate the percentage of loans that have significantly deteriorated. That a rise in interest rates will likely lead to a significant deterioration in credit risk for some floating-rate borrowers, is not controversial. But working out whether they make up 5%, 20% or 35% of the portfolio would appear to be more of an art than science, and no two banks are likely to arrive at the same figure.

The IASB brought some useful clarification on this example in its 25 July 2016 webcast on forward-looking information:

- First, they clarified that one financial instrument cannot exist in stage 1 and in stage 2 at the same time. Therefore, the Board in the above example did not mean that each asset in the portfolio is to be regarded as 20% in stage 2 and 80% in stage 1. Instead, 20% of the assets are in stage 2, even if the bank does not yet know precisely which instruments are in stage 2.
- This allocation is intended to reflect that some assets in the portfolio will respond more adversely to a given change to the macroeconomic factor (e.g., unemployment rate) than others. Therefore, some assets in the portfolio may be considered to have significantly increased in credit risk while others have not. Judgement is required to determine how much of the portfolio moves to stage 2. An entity may, for example, determine that given the range of possible scenarios, 20% of the portfolio moves to stage 2 considering the different level of sensitivity of the assets in the portfolio to the different relevant credit risk drivers.
- As further explained in the next section on using multiple scenarios for the staging assessment (see section 6.7 below), it is important to note that the 20% is not the probability of occurrence of the more adverse scenario. Rather, it reflects the proportion of the portfolio deemed to have already significantly deteriorated based on the most recent probability-weighted average probability of default. This is due to the heightened sensitivity of this proportion of the portfolio to certain macroeconomic factors.

A further issue with the top-down approach is the question of what the lender does if it subsequently finds that differences in risk characteristics emerge within the portfolio, such that certain assets need to be measured using lifetime expected credit losses using the bottom-up approach. A similar question arises if individual assets subsequently need to be measured using lifetime expected credit losses, for instance, because they become 30 days past due. In practice, it is likely that banks, at each reporting date, will first allocate exposures to stage 2 based on an individual assessment and then apply a collective approach to the remaining stage 1 exposures. They are unlikely to 'roll-forward' the collective allowance.

Presumably the proportion of the portfolio expected credit losses in stage 2 can be measured once again using 12-month expected credit losses if economic conditions are expected to improve. However, any assets that are 30 days past due will continue to be treated as stage 2. [IFRS 9.B5.5.19].

Because of these and similar difficulties, we are not currently aware of any banks who are using the top-down approach in the manner set out in the Illustrative Example. Banks prefer to know which loans are measured using lifetime expected credit losses, rather than a notional percentage of the population. In practice, the methods that are being used by banks are closer to a mixture of the bottom-up and top-down approaches, as described in Illustration 6-10 and Illustration 6-11 above. Macroeconomic indicators are assessed, as in the top-down approach, but the effect is determined by assessing the effect on particular exposures. One possible method is to determine the expected migration of loans through a bank's risk classification system, by recalibrating the probabilities of default based on forward-looking data. This could be used to forecast how many additional loans will get downgraded as well as the associated expected credit losses. Another is to focus on more vulnerable categories of lending, such as interest-only mortgages, secured loans with high loan-to-value ratios, or property development loans, and assess how these might respond to the economic outlook. The more information about customers that a lender possesses, the more this might look like the illustrated bottom-up approach. It is likely that banks will use different approaches for different portfolios, depending on how they are managed and what data is available (see section 5.6.3 above for further discussions on post-model overlays and adjustments when incorporating the impact of rare shock events, e.g., the coronavirus pandemic).

How we see it

In practice, lending businesses are likely to use a mixture of the bottom-up and top-down approaches and different approaches for different portfolios, depending on how they are managed and what data is available.

All the examples in the illustrative examples simplify the fact pattern to focus on just one driver of credit losses, whereas in reality, there will be many, and it is not possible to find a historical precedent for the combination of economic indicators that may now be present. Further, to delve into the past to predict the future requires a level of data that lending businesses may lack. The example in IFRS 9 bases the percentage on historical experience, but the past might potentially not be a reliable guide to the future. In practice, lending businesses need to determine the main macroeconomic variables that correlate with credit losses and focus on modelling these key drivers of loss.

The banks can make use of work carried out for stress testing. Also, banks generally use one single model to estimate forward-looking probability of defaults for both the assessment of significant increases in credit risk and the measurement of expected credit losses (see section 5.9.3 above).

6.6 Determining the credit risk at initial recognition of an identical group of financial assets

In practice, entities may hold a portfolio of debt securities that are identical and cannot be distinguished individually (e.g., all securities have the same international securities identification number (ISIN)) and over the lifetime of the portfolio, entities may acquire additional securities or sell some of those previously acquired. In such instances, entities have to determine the credit risk at initial recognition of those securities that remain in the homogeneous portfolio at the reporting date.

IFRS 9 contains no specific guidance on how to calculate the cost of financial assets for derecognition purposes when they are part of a homogenous portfolio. Under IAS 39, which was also silent on this topic, entities used to choose between three cost allocation methods for available-for-sale securities: the average cost method, the first-in-first-out (FIFO) method or the specific identification method. Specific identification can be applied if the entity is able to identify the specific items sold and their costs. For example, a specific security may be identified as sold by linking the date, amount and cost of securities bought with the sale transaction, provided that there is no other evidence suggesting that the actual security sold was not the one identified under this method.

For IFRS 9, the question arises whether entities can continue to apply one of the above methods for debt instruments, not only for determining the cost of the security at derecognition but also for determining their initial credit risk. We believe that:

- The method used for recognising and measuring impairment losses is normally the same as that used for determining the cost allocation method on derecognition.
- A FIFO approach or a specific identification method as described above constitute acceptable accounting policy choices to be applied consistently.
- However, it would not normally be appropriate to use the weighted-average method to determine the credit risk at initial recognition, as averaging the different levels of initial credit risk of debt securities purchased at different dates would result in an identical initial credit risk for each item. It, therefore, would create bias when assessing whether the credit risk of debt securities has increased significantly.

How we see it

The method for determining the credit risk at initial recognition of an identical group of financial assets is normally the same as the method used for determining the cost allocation on derecognition. This would include the FIFO approach or a specific identification method and it would not normally be appropriate to use the weighted-average method.

6.7 Multiple scenarios for the assessment of significant increases in credit risk

At its December 2015 meeting the IFRS Transition Resource Group for Impairment of Financial Instruments discussed not only the need to consider multiple scenarios for measurement of expected credit losses (see section 5.6.1 above), but also for the purposes of assessing whether exposures should be measured on a lifetime loss basis.

Similar to the measurement of expected credit losses, the IFRS Transition Resource Group for Impairment of Financial Instruments members noted that where there is a non-linear relationship between the different forward-looking scenarios and the associated risks of default, using a single scenario would not meet the objectives of IFRS 9. Consequently, in such cases, an entity would need to consider more than one forward-looking scenario. Further, there should be consistency, to the extent relevant, between the information used to measure expected credit losses and that used to assess significant increases in credit risk. An example of when the information might not be relevant is the value of collateral. It may be necessary to calculate the effect of multiple scenarios to value collateral to measure expected credit losses, but this information might not be relevant to assessing significant changes in credit risk unless the value has an effect on the probability of default occurring.²⁴

As with the measurement of expected credit losses, the IFRS Transition Resource Group for Impairment of Financial Instruments members noted that IFRS 9 does not prescribe particular methods of assessing for significant increases in credit risk. Consequently, various methods could be applied, depending on facts and circumstances and these may include both quantitative and qualitative approaches. An entity should not restrict itself by considering only quantitative approaches when considering how to incorporate multiple forward-looking scenarios. Whichever approach is taken, it should be consistent with IFRS 9, considering reasonable and supportable information that is available without undue cost and effort. Once again, this is an area of judgement and so appropriate disclosures would need to be provided to comply with the requirements of IFRS 7 (see section 15 below and Chapter 50).

A further issue was raised at the IFRS Transition Resource Group for Impairment of Financial Instruments meeting, which was not referred to in the minutes but was addressed in the 25 July 2016 IASB webcast. If a number of scenarios are applied to an individual asset, in some of which there is no significant increase in credit risk and in others there is, is it possible that it could be measured partly based on 12-month losses and partly on lifetime losses? It was not the intention of the IASB that an asset is regarded as being in more than one stage at the same time. For staging as well as for measurement, IFRS 9 applies to the unit of account which is the individual financial instrument. The financial asset cannot be considered to have partly significantly deteriorated and partly not. Hence, for instance, if the staging assessment is based on a mechanistic approach which considers the change in the lifetime probability of default, the entity uses the multiple scenario probability-weighted lifetime probability of default to assess whether there has been a significant increase in credit risk. The asset is then measured using the weighted 12-month probability of default if it is considered to be in stage 1, or the weighted lifetime probability of default if it is considered to be in stage 2.

However, as described in section 6.5.3 above, the webcast also noted that, for a collectively assessed portfolio of assets, only a proportion of the portfolio may be deemed to have significantly deteriorated while the rest of the portfolio has not, due to differences in sensitivities of credit risk to a change in a particular parameter.

The IASB also illustrated how multiple scenarios can be reflected in a non-probability of default-based approach, using the example of a scorecard system. If the entity determines that there is non-linearity in the effect of the scenarios on the credit risk of the customers, one possibility is to look at the scorecard inputs and to determine which of these inputs have a non-linear relationship with the macroeconomic parameters. The entity then adjusts the scorecard, for example, using a scaling factor to reflect the impact of non-linearity, assesses whether there has been a significant increase in credit risk and measures expected credit loss on the basis of the adjusted scorecard.

The approach set out in this discussion is broadly the same as ‘the top down’ approach to collective assessments illustrated by Illustration 6-11 in section 6.5.3 above.

It is important to note that the IFRS Transition Resource Group for Impairment of Financial Instruments did not state that it is always necessary to use multiple scenarios and probability-weighted lifetime probabilities of default to assess significant increases in credit risk.

²⁴ IASB Transition Resource Group for Impairment of Financial Instruments, [Meeting Summary](#), 11 December 2015, paras. 58 and 59. Available on the IFRS Foundation's website.

What it did state is that:

- (a) It is necessary to consider more than one scenario if there is non-linearity in the possible distribution of losses.
- (b) Qualitative approaches may be included as well as quantitative ones, so that, for instance, it might be possible to take account of non-linearities by scaling the output from score cards.
- (c) The assessment should be based on reasonable and supportable information that is available without undue cost or effort (see section 5.9.1 above).

Nevertheless, the IFRS Transition Resource Group for Impairment of Financial Instruments did state that there should be consistency, to the extent relevant, between the forward-looking information used for measurement and for the assessment of significant increases in credit risk. There would not always be a direct mapping of the relevant information, because in some cases information might have an impact on the measurement of expected credit losses but not on the assessment of significant increases in credit risk (and *vice versa*). Also, various methods of assessing for significant increases in credit risk could be applied, depending on the particular facts and circumstances, and an entity should not restrict itself by considering only quantitative approaches when considering how to incorporate multiple forward-looking scenarios.

On the 25 July 2016 webcast, the IASB also stressed the importance of adequate disclosures. Because there is no one right approach and because this area involves a high level of judgement, disclosures are very important to enable users of financial statements to understand how entities' credit risk is affected by forward-looking scenarios and how they have affected the application of the expected credit loss model. It would also be useful to disclose if relevant forward-looking information has not been reflected in the assessment of significant deterioration on the basis that it is not reasonable and supportable.

In practice, many banks that use multiple scenarios of lifetime probabilities of default to measure assets in stage 2, use them also for assessing if there has been a significant increase in credit risk. Moreover, as with measurement, banks will need to consider regulators' expectations (see section 7.1 below).

7 Other matters and issues in relation to the expected credit loss calculations

This section discusses other matters and issues that are relevant to applying the IFRS 9 impairment requirements.

7.1 Basel guidance on accounting for expected credit losses

The Basel Committee published the final version of its *Guidance on Credit Risk and Accounting for Expected Credit Losses* (sometimes referred to as ‘the Basel guidance’ or just ‘the guidance’) in December 2015 (see section 1.5 above). The guidance deals with lending exposures, and not debt securities, and does not address the consequential capital requirements.

The guidance was originally drafted for internationally active banks and more sophisticated banks in the business of lending. The final version does not limit its scope but allows less complex banks to apply, ‘a proportionate approach’ that is commensurate with the size, nature and complexity of their lending exposures. It also extends this notion to individual portfolios of more complex banks. It follows that determining what is proportionate will be a key judgement to be made, which is likely to be guided in some jurisdictions by banking regulators. The guidance issued in June 2016 by the GPPC (see section 7.2 below) will also be relevant in making this determination. The final version of the guidance acknowledges that due consideration may also be given to materiality.

The main section of the Basel Committee’s guidance is intended to be applicable in all jurisdictions (i.e., for banks reporting under US GAAP as well as for banks reporting under IFRS) and contains 11 supervisory principles. The guidance is supplemented by an appendix that outlines additional supervisory requirements specific to jurisdictions applying the IFRS 9 expected credit loss model.

It is important to stress that the guidance is not intended to conflict with IFRS 9 (and, indeed, this has been confirmed by the IASB), but it goes further than IFRS 9 and, in particular, removes some of the simplifications that are available in the standard. It also insists that any approximation to what would be regarded as an ‘ideal’ implementation of expected credit loss accounting is designed and implemented so as to avoid ‘bias’. The term ‘avoidance of bias’ is used several times in the guidance and we understand it to have its normal accounting meaning of neutrality. Hence, for instance, if a bank were ever dependent on past-due information to assess whether an exposure is measured on a lifetime expected credit loss basis, it is guided to “pay particular attention to their measurement of the 12-month allowance to ensure that expected credit losses are appropriately captured in accordance with the measurement objective of IFRS 9.”²⁵

Perhaps one of the most significant pieces of guidance provided by the Basel Committee relates to the important requirement in IFRS 9 that expected credit losses are measured using ‘reasonable and supportable information’. The Basel Committee accepts that in certain circumstances, information relevant to the assessment and measurement of credit risk may not be reasonable and supportable and is therefore excluded from the expected credit loss assessment and measurement process. But, given that credit risk management is a core competence of banks, ‘these circumstances would be exceptional in nature’.²⁶ This attitude pervades the guidance. It also states that management is expected “to apply its credit judgement to consider future scenarios” and “The Basel Committee does not view the unbiased consideration of forward-looking information as speculative”.²⁷ The guidance, therefore, establishes a high hurdle for when it is not possible for an internationally active bank to estimate the effects of forward-looking information. It is possible that banking regulators would expect banks to make an estimate of the effects of events with an uncertain binary outcome that is highly significant, such as the result of a referendum as discussed by the IFRS Transition Resource Group for Impairment of Financial Instruments in September 2015 (see section 5.9.5 above).

25 [Guidance on credit risk and accounting for expected credit losses](#), Basel Committee on Banking Supervision, December 2015, para. A55. Available on the Bank for International Settlements’ website.

26 [Guidance on credit risk and accounting for expected credit losses](#), Basel Committee on Banking Supervision, December 2015, para. 22. Available on the Bank for International Settlements’ website.

27 [Guidance on credit risk and accounting for expected credit losses](#), Basel Committee on Banking Supervision, December 2015, para. 21. Available on the Bank for International Settlements’ website.

A connected piece of the guidance relates to another important principle in IFRS 9, that reasonable and supportable information should be available 'without undue cost or effort'. The guidance states that banks are not expected to read this 'restrictively'. It goes on to say that, "Since the objective of the IFRS 9 model is to deliver fundamental improvements in the measurement of credit losses ... this will potentially require costly upfront investment in new systems and processes". Such costs "should therefore not be considered undue".²⁸

Much of the guidance relates to systems and controls and the requirements of the main section that relate to accounting include:

- (1) There should be commonality in the processes, systems, tools and data used to assess credit risk and to measure expected credit losses for accounting and for regulatory capital purposes.²⁹
- (2) When a bank's individual assessment of exposures does not adequately consider forward-looking information, it is appropriate to group lending exposures with shared credit risk characteristics to estimate the impact of forward-looking information, including macroeconomic factors (see section 6.5 above).³⁰ The grouping of lending exposures into portfolios with shared credit risk characteristics must be re-evaluated regularly (including re-segmentation in light of relevant new information or changes in the bank's expectations). Groupings must be granular enough to assess changes in credit risk and changes in a part of the portfolio must not be masked by the performance of the portfolio as a whole.³¹
- (3) 'Adjustments' may be used to address events, circumstances or risk factors that are not fully considered in credit rating and modelling processes. But the Basel Committee expects that such adjustments will be temporary. If the reason for an adjustment is not expected to be temporary, then the processes should be updated to incorporate that risk driver. The guidance goes on to say that adjustments require judgement and create the potential for bias. Therefore, they should be subject to appropriate governance processes.³²
- (4) The "consideration of forward-looking information and macroeconomic factors is considered essential to the proper implementation of an expected credit loss model. It cannot be avoided on the basis that the banks consider the costs to be excessive or unnecessary or because there is uncertainty in formulating forward-looking scenarios". However, the Basel Committee recognises that an expected credit loss is "an estimate and thus may not perfectly predict actual outcomes. Accordingly, the need to incorporate such information is likely to increase the inherent degree of subjectivity in expected credit loss estimates, compared with impairment measured using incurred loss approaches". Also, the Basel Committee recognises that it is not always possible to demonstrate a strong link in formal statistical terms between certain types of information and the credit risk drivers. Consequently, a bank's experienced credit judgement will be crucial in establishing the appropriate level for the individual or collective allowance.³³
- (5) Although the final version of the guidance says less about disclosures than the draft version, given the publication of the Enhanced Disclosure Task Force recommendations, disclosure remains one of the key principles (see section 15 below and Chapter 50).

33 [Guidance on credit risk and accounting for expected credit losses](#), Basel Committee on Banking Supervision, December 2015, paras. 64 and 65. Available on the Bank for International Settlements' website.

The guidance is supplemented by an appendix that outlines additional supervisory requirements specific to jurisdictions applying the IFRS 9 expected credit loss model. The key requirements are outlined below:

- (1) A bank's definition of default adopted for accounting purposes is guided by the definition used for regulatory purposes, which includes both a qualitative 'unlikelihood to pay' criterion and an objective 90-days-past-due criterion, described by the Basel Committee as a 'backstop'.
- (2) The IFRS 9 requirement to assess whether exposures have significantly increased in credit risk "is demanding in its requirements for data, analysis and use of experienced credit judgement". The determination is made "on a timely and holistic basis", considering a wide range of current information. It is critical that banks have processes in place to ensure that financial instruments, whether assessed individually or collectively, are moved from the 12-month to the lifetime expected credit loss measurement as soon as credit risk has increased significantly. Credit losses very often begin to deteriorate a considerable period of time before an actual delinquency occurs and delinquency data are generally backward-looking. Therefore, "the Basel Committee believes that they will seldom on their own be appropriate in the implementation of an expected credit loss approach by a bank." Instead, banks need to consider the linkages between macroeconomic factors and borrower attributes, using historical information to identify the main risk drivers, and current and forecast conditions and experienced credit judgement to determine loss expectations. This applies not only to collective assessments of portfolios but also for assessments of individual loans. The guidance gives the example of a commercial property loan, for which the bank assesses the sensitivity of the property market to the macroeconomic environment and use information such as interest rates or vacancy rates to make the assessment.³⁴
- (3) In assessing whether there has been a significant increase in credit risk, banks should not rely solely on quantitative analysis. The guidance draws banks' attention to the list of qualitative indicators set out in IFRS 9.B5.5.17. Particular consideration should be given to a list of conditions, including an increased credit spread for a particular loan, a decision to strengthen collateral and/or covenant requirements, a downgrade by a credit rating agency or within the bank's internal credit rating system, a deterioration in future cash flows, or an expectation of forbearance or restructuring. Also, the guidance stresses that the sensitivity of the risk of a default occurring to rating downgrades increases strongly as rating quality declines. Therefore, the widths of credit risk grades need to be set appropriately, so that significant increases in credit risk are not masked. Further, "if a decision is made to intensify the monitoring of a borrower or class of borrowers, it is unlikely that such action would have been taken ... had the increase in credit risk not been perceived as significant."³⁵
- (4) Exposures that are transferred to stage 2 and that are subsequently renegotiated or modified, but not derecognised, should not be moved back to stage 1 until there is sufficient evidence that the credit risk over the remaining life is no longer significantly higher than on initial recognition. "Typically, a customer would need to demonstrate consistently good payment behaviour over a period of time before the credit risk is considered to have decreased."³⁶
- (5) IFRS 9 includes a number of practical expedients (see section 6.4 above). However, as banks are in the business of lending and it is unlikely that obtaining relevant information will involve undue cost or effort, the Basel Committee expects their limited use by internationally active banks. For instance:
 - (a) The long-term benefit of a high-quality implementation of an expected credit loss model that takes into account all reasonable and supportable information far outweighs the associated costs.
 - (b) The use of the low credit risk simplification is considered a low-quality implementation of the expected credit loss model and its use should be limited (except for holdings in debt securities, which are out of scope of the guidance). Also, the reference to an investment grade rating in IFRS 9 is only given as an example of a low credit risk exposure. An investment grade rating given by a rating agenda cannot automatically be considered low credit risk because banks are expected to rely primarily on their own credit assessments.
 - (c) Delinquency is a lagging indicator. Therefore, the Basel Committee expects banks not to use the more-than-30-days-past-due rebuttable presumption as a primary indicator of a significant increase in credit risk. Banks may only use the rebuttable presumption as a backstop measure, alongside other, earlier indicators, while any rebuttal of the presumption would have to be accompanied by a thorough analysis to show that 30 days past due is not correlated with a significant increase in credit risk.³⁷

7.2 Global Public Policy Committee (GPPC) guidance

On 17 June 2016, the GPPC published *The implementation of IFRS 9 impairment by banks - Considerations for those charged with governance of systemically important banks* ('the GPPC guidance'). The GPPC is the Global Public Policy Committee of representatives of the six largest accounting networks. This publication was issued to promote high-quality implementation of the accounting for expected credit losses in accordance with IFRS 9 and to help those charged with governance to identify the elements of a high-quality implementation. It was designed to complement other guidance such as that issued by the Basel Committee (see section 7.1 above) and the Enhanced Disclosure Task Force (see Chapter 50). It does not purport to amend or interpret the requirements of IFRS 9 in any way. The first half of the GPPC guidance sets out key areas of focus for those charged with governance. This includes governance and controls, transition issues and ten questions that those charged with governance might wish to discuss. The second half of the guidance sets out a sophisticated approach to implementing each aspect of the requirements of IFRS 9, along with considerations for a simpler approach and what is not compliant. Where relevant to understanding the accounting requirements of IFRS 9, this guidance is reflected in this chapter.

The GPPC guidance regards determination of the level of sophistication of the approach to be used as one of the key areas of focus for those charged with governance. Consequently, it provides guidance on how to make this determination for particular portfolios. It sets out factors to consider at the level of the entity, such as the extent of systemic risk that the bank poses, whether it is listed or a public interest entity, the size of its balance sheet and off balance sheet credit exposures, and the level and volatility of historical credit losses. Portfolio-level factors include its size relative to that of the total balance sheet and its complexity, the sophistication of other lending-related modelling methodologies, the extent of available data, the level of historical losses and the level and volatility of losses expected in the future. The document stresses that a simpler approach is not necessarily a lower quality approach if it is applied to an appropriate portfolio.

Also, on 28 July 2017, the GPPC issued its second paper titled *The Auditor's Response to the Risks of Material Misstatement Posed by Estimates of Expected Credit Losses under IFRS 9*. This second paper was written in an effort to assist audit committees in their oversight of the bank's auditors with regard to auditing expected credit losses. It is addressed primarily to the audit committees of systemically-important banks (SIBs) because of the relative importance of SIBs to capital markets and global financial stability but is relevant for other banks as well. It ought to be read in conjunction with the initial guidance published in 2016.

7.3 Measurement dates of expected credit losses

7.3.1 Date of derecognition and date of initial recognition

Frequently asked questions

Question 7-1: Whether there is a requirement to measure Expected Credit Losses at dates other than the reporting date, namely the date of derecognition and the date of initial recognition?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 22 April 2015 - Agenda paper no. 7)

Impairment must be assessed and measured at the reporting date. IFRS 9 also requires a derecognition gain or loss to be measured relative to the carrying amount at the date of derecognition (see Chapter 50). This necessitates an assessment and measurement of expected credit losses for that particular asset as at the date of derecognition, as was confirmed by the discussions at the April 2015 IFRS Transition Resource Group for Impairment of Financial Instruments meeting (see section 1.4 above).

Essentially, the calculation of derecognition gains or losses is a two-step process:

- Step 1: expected credit losses are remeasured at the date of derecognition and presented in the separate impairment line item in the statement of profit or loss as per IAS 1.82(ba) *Presentation of Financial Statements*. The change in expected credit loss estimate should still reflect the reporting entity's view rather than the market's view of credit losses based upon the remaining contractual life of the financial asset. Also, the residual life of the asset should not be deemed to be nil because of the imminent sale and impairment losses that have not materialised should not be mechanically reversed to reflect the fact that the reporting entity will no longer be holding the debt security. This is consistent with Illustrative Examples 13 and 14 of IFRS 9. In particular, a footnote to the last journal entry in Illustrative Example 14 explains that the loss on sale includes the accumulated impairment amount.
- Step 2: Gains or losses on derecognition are calculated taking into account all expected credit losses for financial assets measured at amortised cost and all cumulative gains or losses previously recognised in other comprehensive income including those related to expected credit losses for financial assets measured at fair value through other comprehensive income. Unlike the requirement to present gains and losses arising from the derecognition of financial assets measured at amortised cost as a separate line item in the statement of profit or loss as per IAS 1.82(aa), there is no specific presentation requirement for financial assets measured at fair value through other comprehensive income.

Since that discussion, the IFRS Transition Resource Group for Impairment of Financial Instruments has discussed whether the expected sales of impaired assets should be reflected in the calculation of expected credit losses (see section 5.8.2 above). Given their conclusion that an entity should, it is quite possible that there will be little or no additional losses to record on derecognition that have not already been reflected in the impairment cost.

A similar issue is whether impairment needs to be measured at the date that an asset is modified (see section 8 below).

At the April 2015 meeting, the IFRS Transition Resource Group for Impairment of Financial Instruments also discussed a more difficult question, whether impairment must be measured as at the date of initial recognition for foreign currency monetary assets. The significance of this is whether subsequent gains and losses arising from foreign currency retranslation in the first accounting period should be calculated based on the initial gross amortised cost or a net amount, after deducting an impairment allowance. This would affect the allocation of subsequent gains and losses of the asset in this period to impairment or to foreign currency retranslation, so that it would be reported in different lines of the profit or loss account.

Differing views were expressed:

- A few IFRS Transition Resource Group for Impairment of Financial Instruments members supported the view that while IFRS 9 does not expressly require expected credit losses to be measured at the date of initial recognition, the requirements of other IFRS accounting standards, e.g., IAS 21 *The Effects of Changes in Foreign Exchange Rates*, may result in an entity measuring expected credit losses at the date of initial recognition. Also, Illustrative Example 14 in IFRS 9 implies the need to include expected credit losses on initial recognition in the measurement of foreign exchange gains and losses in respect of a foreign currency-denominated asset (see Illustration 9-2 in section 9.2 below). However, these members questioned the frequency with which an entity needed to perform that calculation and pointed out that considerations of materiality would be a key factor in making this decision.
- Some other IFRS Transition Resource Group for Impairment of Financial Instruments members were of the view that an entity is required to measure a financial asset at its fair value upon initial recognition and that consequently measuring expected credit losses at initial recognition would be inconsistent with that requirement. [IFRS 9.5.1.1]. IFRS 9 includes impairment as part of the subsequent measurement of a financial asset and, consequently, only requires an entity to begin measuring expected credit losses at the first reporting date after initial recognition (or on derecognition if that occurs earlier). [IFRS 9.3.2.12, IFRS 9.5.5.3, IFRS 9.5.5.5, IFRS 9.5.5.13]. While the requirements of other IFRS accounting standards should be applied to the loss allowance at that point, the application of those requirements should not result in an entity having to measure expected credit losses at a date earlier than that specifically required by IFRS 9.

The IFRS Transition Resource Group for Impairment of Financial Instruments also noted that the Illustrative Examples are non-authoritative and illustrate only one way of applying the requirements of IFRS 9. Measuring a 12-month expected credit loss using point in time, forward-looking information, every time that a foreign currency exposure is first recognised would not be feasible. Given that there was no consensus on this issue, we expect that there may be diversity in practice.

7.3.2 Trade date and settlement date accounting

For financial assets measured at amortised cost or at fair value through other comprehensive income, IFRS 9 requires entities to use the trade date as the date of initial recognition for the purposes of applying the impairment requirements. [IFRS 9.5.7.4]. This means that entities that use settlement date accounting for regular way purchases of debt securities may have to recognise a loss allowance for securities which they have purchased but not yet recognised and, correspondingly, no loss allowance for securities that they have sold but not yet derecognised. (See Chapter 45 for further details on trade date accounting and settlement date accounting).

Irrespective of the accounting policy choice for trade date accounting versus settlement date accounting, the recognition of the loss allowance on the trade date ensures that entities recognise the loss allowance at the same time; otherwise, entities could choose settlement date accounting to delay recognising the loss allowance until the settlement date. The effect of this is similar to accounting for fair value changes on financial assets measured at fair value through other comprehensive income and those measured at fair value through profit or loss when settlement date accounting is applied (i.e., a measurement change needs to be recognised in profit or loss and the statement of financial position even if the related assets that are being measured are only recognised slightly later). It is also consistent with the treatment of expected credit losses in loans, where an expected credit loss is calculated in respect of a loan commitment between the date that the commitment is made and the loan is drawn down.

For settlement date accounting, the recognition of a loss allowance for an asset that has not yet been recognised raises the question of how that loss allowance is presented in the statement of financial position. The time between the trade date and the settlement date is somewhat similar to a loan commitment in that the accounting is off balance sheet, which suggests presentation of the loss allowance as a provision.

In practice, some entities tend to opt for settlement date accounting for regular way securities recorded at amortised cost, because they do not need the additional systems capabilities to account for the securities on trade date (i.e., they do not need to account for them until settlement date).

7.4 Interaction between the initial and subsequent measurement of debt instruments acquired in a business combination and the impairment model of IFRS 9

For debt instruments that are acquired in a business combination, the initial recognition and measurement is accounted for under IFRS 3. Consistent with IFRS 9 and IFRS 13 *Fair Value Measurement*, IFRS 3 requires financial assets acquired in a business combination to be measured by the acquirer on initial recognition at their acquisition-date fair value (see IFRS 3.18). (See Chapter 45 and Chapter 10). Paragraph B41 of the Application Guidance to IFRS 3, as amended by IFRS 9, elaborates on this, and explains that no loss allowance is recognised as part of the initial measurement of debt instruments that are acquired in a business combination: [IFRS 3.B41]

Extract from IFRS 3

Assets with uncertain cash flows (valuation allowances)

B41 The acquirer shall not recognise a separate valuation allowance as of the acquisition date for assets acquired in a business combination that are measured at their acquisition-date fair values because the effects of uncertainty about future cash flows are included in the fair value measure. For example, because this IFRS requires the acquirer to measure acquired receivables, including loans, at their acquisition-date fair values in accounting for a business combination, the acquirer does not recognise a separate valuation allowance for the contractual cash flows that are deemed to be uncollectible at that date or a loss allowance for expected credit losses.

Consequently, the accounting for impairment of debt instruments measured at amortised cost or fair value through other comprehensive income under IFRS 9 does not affect the accounting for the business combination.

- At the acquisition date, the acquired debt instruments are measured at their acquisition-date fair value in accordance with IFRS 3. No loss allowance is recognised as part of the initial measurement of debt instruments that are acquired in a business combination. This is the same treatment as would be the case for the acquisition of a portfolio of assets which is not part of a business combination.
- After their original recognition, the subsequent accounting for debt instruments acquired in a business combination is in the scope of IFRS 9. The impairment requirements in IFRS 9.5.5 are part of the subsequent measurement of those debt instruments (see IFRS 9.5.2.1 and 5.2.2 as well as the structure of the standard, i.e., that initial measurement is addressed in IFRS 9.5.1 and subsequent measurement is addressed in IFRS 9.5.2). Consequently, the recognition of an expected credit loss allowance in IFRS 9.5.5 occurs at the first reporting date after the business combination (see IFRS 9.5.5.3 and 5.5.5, which refer to measurement at the reporting date). This results in recognising a corresponding impairment loss in profit or loss (see IFRS 9.5.5.8). Therefore, at the first reporting date after the business combination, following the guidance in IFRS 9, a loss allowance is recognised. This will result in an impairment loss that is recognised in profit or loss (rather than an adjustment to goodwill), just as would be the case if the entity were to originate those assets or acquire them as a portfolio, rather than acquire them through a business combination. The assets will all be measured on the basis of 12-month expected credit losses unless the assets are purchased or originated credit-impaired or the assets have increased significantly in credit risk between the date of the business combination and the first reporting date.

How we see it

Despite the colloquial reference to a 'day one' loss that results from the expected credit loss impairment model in IFRS 9, it is important to understand that the recognition of a loss allowance for newly acquired (whether purchased or originated) debt instruments that are in the scope of the impairment requirements in IFRS 9.5.5 is a matter of subsequent measurement of those financial instruments. This means that the acquirer recognises the loss allowance for all debt instruments acquired in a business combination (that are subject to impairment accounting) in the reporting period that includes the business combination but not as part of that business combination, and with a corresponding impairment loss in profit or loss. As a result, these acquired assets are carried at a value below their fair value by what is often referred to as 'day two', when the 12-month expected credit loss is booked. This may seem counter-intuitive to many preparers and users of financial statements, but is clearly what is intended by IFRS 9.

The only exception to the need to record expected credit losses on day two is the specific accounting for purchased or originated credit-impaired financial assets (see section 3.3 above). This applies to financial assets which are already credit-impaired at the acquisition date. A financial asset is credit-impaired when one or more events that have a detrimental impact on the estimated future cash flows of that financial asset have occurred (see section 3.1 above). Financial assets that are already credit-impaired at the acquisition date are not accounted for under the 'general approach' of the impairment model of IFRS 9 but instead follow a different application of the impairment model (see IFRS 9.5.5.13 and 5.5.14). This does not involve recognising the loss allowances for 12-month or lifetime expected credit losses. For such assets, the effective interest rate is determined using a cash flow estimate that includes all initial lifetime expected credit losses and no separate allowance is initially made for expected credit losses, as the expected credit loss is part of the 'credit-adjusted effective interest rate'. Subsequently, the cash flow estimate used for calculating amortised cost, including expected credit losses, is updated at each reporting date, so that any cumulative changes in lifetime expected credit losses since initial recognition is recognised as a loss allowance and corresponding gain or loss in profit or loss as expectations change. This differs from financial assets that are not purchased or originated credit-impaired, where an allowance must be made for expected credit losses (see sections 3.1 and 3.3 above).

It follows that, on a business combination, the acquirer needs to classify the acquired debt instruments that will be recorded at amortised cost or at fair value through other comprehensive income, according to whether they are purchased credit-impaired or not. If not, they will be regarded as stage 1 assets and be subject to a 12-month expected credit loss. If they are purchased credit-impaired, then there will be no need for an additional expected credit loss unless there is a subsequent change in estimated lifetime expected credit loss (see section 3.3 above). Furthermore, these purchased credit-impaired loans will always be treated as such and are never subsequently subject to the staging requirements. Also, none of the acquired assets, either performing or purchased credit-impaired, will be classified as stage 2 or stage 3 at the date of initial recognition.

A further issue for debt instruments acquired in a business combination is the application of the rebuttable presumption that there has been a significant increase in credit risk if the loan is 30 days past due (see section 6.2.2 above) and that default does not occur later than when a financial asset is 90 days past due (see section 5.1 above). For example, if loans are acquired two days before the acquirer's reporting date when they are already 29 days past due or 89 days past due, and if the acquirer were to apply the above rebuttable presumptions, such loans would be presumed to have significantly increased in credit risk (i.e., moved from stage 1 to stage 2) and have defaulted (i.e., moved from stage 1 to stage 3) respectively as at the reporting date.

- For the loans that were 29 days past due, arguably, given the heightened credit risk as at the acquisition date, the loans are unlikely to have significantly increased in credit risk over the short period of two days. Moving the loans from stage 1 to stage 2 would not be consistent with the relative measurement approach of the IFRS 9 impairment model, which is intended to track and determine whether there has been a significant increase in credit risk since initial recognition (see section 6 above). However, the acquirer is permitted to rebut the presumption and apply it only to those loans that are not past due when purchased, or else 'start the clock' only at the date of acquisition (see section 6.2.2 above for further discussion on the 30 days past due rebuttable presumption).
- For the loans that were 89 days past due, similar to the issue for loans that were 29 days past due, moving the loans from stage 1 directly to stage 3 could potentially not result in useful information for the users of the accounts. Acquirers are recommended to consider all the criteria set out in IFRS 9 to determine whether such loans were actually purchased credit-impaired (see section 3.3 above) and not to rely solely on the days past due.

7.5 Interaction between expected credit losses calculations and fair value hedge accounting

For a financial asset that becomes credit-impaired, IFRS 9 requires impairment to be measured by reference to the gross carrying amount of the asset, which would include the fair value hedge adjustment. [IFRS 9.B5.5.33]. Otherwise, a part of the asset's carrying amount would not have a loss allowance or the loss allowance would be overstated (in case of a negative fair value hedge adjustment). The effect of fair value hedge accounting is to adjust the effective interest rate, which affects the rate used to discount expected future cash flows. The rationale for this is that the original interest rate before the hedge becomes irrelevant once the carrying amount of the loan is adjusted for any changes in its fair value attributable to interest rate movements. Therefore, for a credit-impaired financial asset in stage 3, the effective interest rate would be adjusted to reflect any fair value hedge adjustment.

However, under the expected credit loss impairment model an allowance is required for all assets, i.e., including assets in stages 1 and 2, in addition to assets in stage 3. Hence, if the discount rate were to be adjusted whenever fair value hedge accounting is applied, then all fair value hedge adjustments would need to be taken into account in calculating expected credit losses. This would give rise to significant operational challenges.

IFRS 9 is not explicit on this matter, but two points in IFRS 9 would seem to be relevant. First, except for credit-impaired assets, the expected credit loss requirements are not based on an asset's 'carrying amount' but on the contractual cash flows that are expected to be lost. Second, IFRS 9 only requires a fair value hedge adjustment to be amortised when the hedged item ceases to be adjusted for changes in fair value attributable to the risk being hedged, which can be read to imply that until then there is no need to adjust the effective interest rate, and hence the rate used to discount expected credit losses. [IFRS 9.6.5.10].

We believe the requirement is not clear and, so at least until it is clarified potentially as part of the hedge accounting PIR, there is an accounting policy choice for exposures that are the designated hedged items in fair value hedge relationships. One approach would be to adjust the effective interest rate whenever a fair value hedge adjustment is made and hence change the interest rate used to discount expected credit losses. The other approach would be not to adjust the effective interest rate or otherwise take into account the fair value hedge adjustment until the effective interest rate is adjusted to amortise the fair value hedge adjustment. [IFRS 9.6.5.8]. Such an adjustment to the effective interest rate is permitted to commence at any time but would, at the latest, be required when hedge accounting ceases or when the financial asset becomes credit-impaired, i.e., moved to stage 3 (see Chapter 49).

How we see it

Entities have an accounting policy choice for exposures that are the designated hedged items in fair value hedge relationships, i.e., to adjust the effective interest rate whenever a fair value hedge adjustment is made and hence, change the interest rate used to discount expected credit losses, or not to adjust the effective interest rate until the fair value hedge adjustment is required to be amortised.

7.6 Changes in expected credit loss methodologies - errors, changes in estimates or changes in accounting policies

Many entities, having now had some experience of applying IFRS 9, may be considering changing various aspects of their expected credit loss methodologies. The potential changes could include the correction of errors found in the model, updating probability of default, loss given default and exposure at default for recent experience, making changes to how significant increases in credit risk are assessed, and amending the definition of default and write-off policies. The question that these potential amendments pose is whether they are accounted for as prior year errors or changes in accounting policies, both of which (if material) would be adjusted for retrospectively, or changes in estimates which would be accounted for as they arise.

The majority of such changes are likely to be changes in estimates. The only changes that will likely be treated as errors are those that are "omissions from, and misstatements in, the entity's financial statements for one or more prior periods arising from a failure to use, or misuse of, reliable information that:

- (a) was available when financial statements for those periods were authorised for issue; and
- (b) could reasonably be expected to have been obtained and taken into account in the preparation and presentation of those financial statements." [IAS 8.5]

Examples of errors would include failure to calculate expected credit losses on all relevant exposures, errors in input data and incorrect spreadsheet formulae. Most amendments to expected credit loss calculation methods, including use of more sophisticated or more up to date data, revisions to formulae or measurement on a more granular basis, are likely to be changes in estimates. It is unlikely that amendments to the calculation approach would be regarded as a change in accounting policy.

If changes are made to how credit risk is assessed for the staging assessment, care must be taken to distinguish between changes in how the risk is perceived and how it is measured, and changes in what is regarded as 'significant'. In contrast, the effect of a change of what is deemed to be 'significant' would normally be treated as a change in estimate.

How we see it

In general, it is not appropriate to reassess the credit risk of a financial asset on initial recognition, i.e., the probability of default on origination is not revised if the expected credit loss model is modified or improved. If the initial credit risk turns out to be riskier than expected, then the initial credit risk is not amended; it is possible that the asset will be transferred to stage 2 and the profit or loss impact would be accounted for as a change in estimate. On the other hand, if all that is amended is the way that the credit risk is measured, such as expressing the risk in terms of 12-month probability of defaults as opposed to lifetime probability of defaults, or using a different definition of default, it may be necessary to recalibrate the initial credit risk using the new measurement basis, so as to measure initial and current credit risk on a consistent basis.

7.7 Securitisations and special purpose entities

Securitisation transactions are carried out to transfer risk and/or raise finance from external investors by enabling them to invest in parcels of specific financial assets such as mortgage loans, credit card receivables, other consumer loans, or lease receivables. In a relatively simple structure, a special purpose entity issues notes to investors and lends the money raised to an entity (the 'originator'), secured by the portfolio of assets, either with recourse to the originator if the cash flows on the portfolio are insufficient to repay the loan, or sometimes with no recourse.

A typical more complicated structure involves the originator selling the portfolio of loans to the special purpose entity. In either case, the special purpose entity's equity share capital, which will typically be small, will often be owned by a trustee on behalf of a charitable trust. The loans will often be issued in series of tranches, with varying levels of risk, established through a 'waterfall' of payments, and at different rates of interest to reflect the risk. The originator will often continue to administer the loans as before, for which it will receive a service fee from the special purpose entity (see Chapter 48).

Some of the common issues that have arisen in practice in relation to securitisations and special purpose entities include contractually linked instruments and subordinated interests (see section 6.1.2 above), the application by the special purpose entity of the expected credit loss requirements when the transferor is not able to derecognise the portfolio of loans (see section 7.7.1 below), and accounting for a financial liability issued by an special purpose entity (see section 7.7.2 below).

7.7.1 Expected credit loss requirements for the special purpose entity if the transferor is not able to derecognise the portfolio of loans

In many securitisation structures, the originator will retain some form of interest in the transferred assets which will preclude derecognition of the assets by the originator.

In the simplest types of structures, where the special purpose entity just lends money to the originator, secured on the portfolio, the special purpose entity will recognise this loan and measure expected credit losses accordingly. If the loan is without recourse to the originator, then the collateral value of the portfolio will be the most important element of the calculation.

In more complex cases, where the portfolio has been sold by the originator to the special purpose entity, the originator may retain an interest through various different mechanisms. These can include, for example, the provision of guarantees or put options, an obligation to substitute non-performing loans, deferred consideration, or by the originator investing in a junior tranche of the notes issued by the special purpose entity. In each case, the special purpose entity does not recognise the transferred assets, but recognises a 'deemed loan' receivable from the originator for the amount of the proceeds paid to buy the transferred assets (see Chapter 48).

The 'deemed loan' is a financial asset which, following a similar approach to the classification of contractually linked instruments (as described in Chapter 44), will often qualify to be recorded at amortised cost or at fair value through other comprehensive income. Assuming it is not measured at fair value through profit or loss, as described in section 6.1.2 above, it is subject to the expected credit loss requirements of IFRS 9. However, IFRS 9 does not set out how the expected credit losses on the deemed loan are determined and whether the performance of the underlying loans are reflected in the measurement of the deemed loan in the standalone accounts of the special purpose entity.

The special purpose entity is exposed to two sources of risk on the deemed loan: (1) the credit risk of the originator, in effect collateralised by the portfolio of loans, and (2) an exposure to the underlying portfolio, to the extent that the originator does not retain all the risks. For instance, if the originator indemnifies the special purpose entity for the first 5% of impairment losses, the special purpose entity is exposed to the originator if it is unable to pay out on the indemnity, but also to the underlying loans to the extent that losses exceed 5%. Although the second of these risks is not strictly a credit risk arising on the deemed loan, similar to the treatment of contractually linked instruments (see section 6.1.2 above), both of these sources of risk would be included by the special purpose entity in the measurement of expected credit losses.

It follows that, when determining whether there has been a significant increase in credit risk on the deemed loan, depending on the terms of the arrangement, the special purpose entity is likely to need both to look through to the staging of the underlying loans but also to take into account any change in the originator's credit risk. If the originator retains all the risks associated with the underlying loans, then the determination would only consider the originator's ability to pay.

Some securitisations are structured such that the special purpose entity is exposed to a very low risk of loss. This might be achieved, for instance, through the originator being paid deferred consideration dependent on the amounts realised from the loans or, if the special purpose entity lends to the originator secured by the loans and ensuring that there is sufficient excess collateral to absorb any losses expected to arise. In these circumstances it is possible that the special purpose entity's expected credit losses may be immaterial.

As will be apparent from this brief discussion, securitisation structures vary significantly, and each transaction will need to be assessed based on its own facts and circumstances. Disclosures will also play an important role in providing useful information to the users of the accounts with respect to the securitisation arrangements in place, the exposure to the originator, the credit quality of the underlying loans and how impairment is assessed.

7.7.2 Accounting for a financial liability issued by a special purpose entity

In many securitisation structures, a special purpose entity invests in a portfolio of loans and raises funds by issuing listed notes to investors. The special purpose entity's contractual obligations on the listed notes are linked to the performance of the loans less the interest spread as, typically, the listed notes bear an interest rate slightly lower than the loans to allow the special purpose entity to earn a spread that is sufficient to cover its operating costs and/or to provide some loss absorption capital. The retention of the interest spread and inability of the special purpose entity to pass the cash flows received from the loan to the noteholder 'without material delay' usually result in the special purpose entity failing the 'pass-through' test for the loans and so the special purpose entity cannot derecognise them (see Chapter 48).

Assuming that the loans held by the special purpose entity are recorded at amortised cost (or fair value through other comprehensive income), under IFRS 9, the special purpose entity is required to record expected credit losses on the loans. However, any losses suffered on the loans will be borne by the noteholders, due to the contractual linkage feature. This raises the question on how the linkage feature is accounted for.

In our view, the linkage feature is accounted for as part of the listed notes liability. In most circumstances, the linkage feature is not a credit derivative that is embedded in a host debt instrument and required to be separated (for instance, because it would allow one party to transfer the credit risk of a particular reference asset, which it may not own, to another party). [IFRS 9.B4.3.5(f)]. If the linkage feature is closely related to the liability (see Chapter 42), it is not separated as an embedded derivative, and is therefore required to be accounted for as part of the amortised cost of the liability. In such instances, any revisions to the estimated contractual cash payments on the listed notes due to the linkage feature is accounted for as an adjustment to the amortised cost of the noteholder liability that is recognised in profit or loss as per IFRS 9.B5.4.6 (see Chapter 46).

How we see it

The contractual linkage feature, where any losses suffered on the loans will be borne by the noteholders, is accounted for as part of the listed notes liability. Any revisions to the estimated contractual cash payments on the listed notes due to the linkage feature is accounted for as an adjustment to the amortised cost of the noteholder liability (discounted at the effective interest rate) and recognised in profit or loss.

Although the linkage feature might be thought of as a financial guarantee of the special purpose entity's loans, as it has the effect of transferring credit losses on the loans from the special purpose entity to the noteholders, it cannot be accounted for as a credit enhancement of the loans and thereby reduce the expected credit losses. Such a treatment is not consistent with the requirements of IFRS 9 and the IFRS IC discussion that if a credit enhancement is required to be recognised separately by IFRS accounting standards, an entity cannot include the cash flows expected from it in the measurement of expected credit losses (see section 5.8.1.A above).

As a consequence of accounting for the linkage feature as part of the listed notes liability, while the special purpose entity will recognise gains on the linkage feature if the loans deteriorate, as it records higher expected credit losses on the loans, the gains recognised under IFRS 9.B5.4.6 are unlikely to match the expected credit loss impairment expense, giving rise to some volatility of earnings. This is because the expected credit losses are calculated based on the probability-weighted amount of credit losses that is based on 12-month expected credit losses if the loans are in stage 1 and lifetime expected credit losses if the loans are in stages 2 and 3, whilst the gains recognised under IFRS 9.B5.4.6 are calculated based on the present value of the estimated future cash receipts. A possible approach to reduce the effect of this accounting mismatch is, on initial recognition, to irrevocably designate the loans and notes at fair value through profit or loss in order to eliminate or significantly reduce the measurement or recognition inconsistency, in accordance with IFRS 9.4.1.5 and 4.2.2 (see Chapter 44).

7.8 Measuring expected credit losses during the coronavirus pandemic

7.8.1 Introduction

A major challenge that commenced in 2020 for the application of the IFRS expected credit loss model was the coronavirus pandemic. The virus significantly affected the world economy and also resulted in significant volatility in the financial and commodities markets. Many countries imposed travel bans on millions of people and many more were subject to quarantine measures. Businesses had to deal with lost revenue and disrupted supply chains. This gave rise to liquidity issues for many entities and also had consequential impacts on the credit quality of entities along the supply chain and also had knock on effects on retail loan portfolios (consumer and mortgage loans) as many businesses had to reduce staff numbers. The deterioration in credit quality of loan portfolios and trade receivables, as a result of the pandemic had a significant impact on expected credit loss measurement. In responding to these challenges, certain governments and central banks introduced, or directed or encouraged commercial banks to introduce, various types of relief measures. The consequence was that there were two sources of uncertainty for the calculation of expected credit losses: first, the potential development and consequences of the virus and, second, the extent and effect of the various relief measures. Whilst the coronavirus pandemic has largely abated and does not pose the same health and macroeconomic threat now, it is still worth considering the guidance issued by the IASB, governments and regulators in response to the uncertainty around the calculation of ECL caused by the crisis as the principles of the guidance provided may be applicable to other macroeconomic phenomena that could arise in future.

7.8.2 Guidance

A number of prudential and securities regulators, including the European Banking Authority, the European Central Bank, the European Securities and Market Authority, the Prudential Regulation Authority in the United Kingdom and The Office of the Superintendent of Financial Institutions in Canada (the regulators) published guidance on the regulatory and accounting implications of the pandemic. The IASB closely engaged with many prudential and securities regulators and others regarding the application of IFRS 9 in the context of the coronavirus pandemic.

On 27 March 2020, the IASB published a document for educational purposes, *IFRS 9 and covid-19 - Accounting for expected credit losses applying IFRS 9 Financial Instruments in the light of current uncertainty resulting from the covid-19 pandemic*. The document was broadly consistent with the guidance from the regulators and emphasised the following:

- IFRS 9 requires the application of judgement and both requires and allows entities to adjust their approach to determining expected credit losses in different circumstances.
- To assess significant increases in credit risks, IFRS 9 requires that entities assess changes in the risk of a default occurring over the expected life of a financial instrument. Both the assessment of significant increases in credit risk and the measurement of expected credit losses are required to be based on reasonable and supportable information that is available to an entity without undue cost or effort (see section 5.9.5 above).

- Entities were required to develop estimates based on the best available information about past events, current conditions and forecasts of economic conditions. In assessing forecast conditions, consideration should have been given both to the effects of coronavirus and the significant government support measures being undertaken (see sections 5.9.3, 5.9.5, and 5.8.1.C above).
- It was likely to be difficult at this time (March 2020) to incorporate the specific effects of coronavirus and government support measures on a reasonable and supportable basis. However, changes in economic conditions should be reflected in macroeconomic scenarios and if the effects of coronavirus could not be reflected in models, post-model overlays or adjustments would need to be considered
- Although circumstances at the time were difficult and created high levels of uncertainty, if expected credit loss estimates were based on reasonable and supportable information and IFRS 9 was not applied mechanistically, useful information could be provided about expected credit losses.

The European Central Bank also issued on 1 April 2020 *IFRS 9 in the context of the coronavirus (covid-19) pandemic* that emphasised the importance of identifying and reporting asset quality deterioration. Subsequently, on 4 December 2020, the European Central Bank issued a letter to the CEO of banks *Identification and measurement of credit risk in the context of the coronavirus (covid-19) pandemic*. The purpose of the letter was to provide banks with guidance on sound credit risk management policies and procedures to identify and measure credit risk in the context of coronavirus pandemic.

7.8.3 Calculation of expected credit losses

Whether the impact of an event such as the coronavirus pandemic was reflected in an individual expected credit loss assessment (estimating the probability of default on an individual basis), factored into the scenario analysis of future macroeconomic conditions on a collective basis, or adjusted through management overlays, depended on the entity's systems and processes and the facts and circumstances. In practice, entities were likely to consider a combination of these approaches. In estimating the impact of the event, entities needed to be careful to avoid double-counting the effects of the various assumptions applied in individual assessments, macroeconomic scenarios and management overlays.

For the purpose of measuring expected credit loss and for determining whether a significant increase in credit risk had occurred, an entity grouped financial instruments on the basis of shared credit risk characteristics and reasonable and supportable information available on a portfolio basis. The occurrence of the coronavirus pandemic might have changed the risk characteristics of certain loans or receivables, because the respective borrowers or customers might have engaged in businesses, or been located in areas, which had become affected, or were more prone to be affected, by the pandemic. Therefore, entities considered (re)segmenting (sub)portfolios as appropriate.

In abnormal circumstances such as those created by the coronavirus pandemic, it might take time before entities detect actual changes in risk indicators for a specific counterparty and be able to reassess the affected exposures. In order to accelerate the reflection of such changes in credit quality not yet detected at an individual borrower level, it might have been appropriate to adjust ratings and the probabilities of default on a collective basis, considering risk characteristics such as the industry or geographical location of the borrowers (see section 6.5 above).

The impact of the coronavirus pandemic was not specific to banks. Corporates using a provision matrix approach to calculate expected credit loss for trade receivables would have needed to make appropriate adjustments to their historical loss rates and reflect the current economic environment as well as forward looking information. For example, a supplier of products or services to the airline industry would likely have had to consider that the probability of default (or loss rates, if a provision matrix approach is used) of its customers had increased irrespective of specific events identified at the level of individual counterparties. Many methods for performing collective assessments make use of historical information, which potentially are not relevant in the circumstances. Further, it might have been necessary to reconsider if loans needed to be segmented differently than in the past to reflect the risk characteristics.

In estimating probability of default, loss rates and expected credit loss, entities considered the effect of any state aid plans to support customers through various measures (e.g., refinancing measures or other forms of financial support, including guarantees). Additionally, entities using multiple economic scenarios when estimating expected credit losses updated these scenarios to reflect the change in circumstances.

Many financial institutions consider multiple macroeconomic scenarios in the assessment of expected credit losses (see section 6.7 above). In addition to updating gross domestic product expectations for the various scenarios, a challenge was to estimate how the impact of the coronavirus pandemic and any related government programmes affected specific sectors, regions and borrowers, especially as the details surrounding many government programmes continued to evolve.

The IASB educational document noted that a number of assumptions and linkages underlying the way expected credit losses had been implemented prior to the pandemic might no longer hold in such an environment. For example, the relationship between gross domestic product and other macroeconomic variables, such as unemployment and interest rates, and sector-specific variables, such as oil prices, was very likely to be different from what had been experienced in the past and reflected in economic forecasting models. The probability weightings assigned to macroeconomic scenarios might also need to have been revisited.

Lenders also needed to assess how the value of collateral, such as the homes underlying mortgages or commercial property prices, would develop over the next few years. They would also need to take into account any guarantees from governments or other parties that were considered integral to the loans (see section 5.8.1.C above), having assessed the credit standing of the guarantor.

In estimating overlays, entities might consider historical experience. However, it appears clear that the widespread nature and severity of the consequences of the coronavirus pandemic was not directly comparable with any recent similar events. It might have been appropriate for this purpose, to plot several possible scenarios of what might have happened over the forecasting period and assign weightings to them, to ensure that any overlay reflected the inherent uncertainty and non-linearity of potential outcomes.

The IASB noted in their educational material that IFRS 9 requires the application of judgement and both requires and allows entities to adjust their approach to determining expected credit losses in different circumstances.

7.8.4 Determining whether there has been a significant increase in credit risk

In the context of the coronavirus pandemic, one of the accounting issues was whether concessions made by lenders, such as changes in payment terms and the granting of payment holidays, would result in loans being move from stage 1 to stage 2.

If payment terms were extended in light of the economic circumstances arising from the coronavirus pandemic, the terms and conditions of the extension would have been assessed to determine their impacts on the expected credit loss estimate as well as any other accounting impacts. For example, if the payment terms of a receivable were extended from 90 days to 180 days, this would likely not be considered a substantial modification of the receivable (see section 8 below). However, such an extension might result in an increase in probability of default, which would, in turn, affect the measurement of expected credit loss. For entities which did not apply the simplified model (see section 3.2 above), such extension might also result in moving the receivable to stage 2, depending on the extent and terms of the payment extension. However, if the same extension of payment terms was offered to an entire class of customers irrespective of individual circumstances, this generally would not result, by itself, in a stage movement.

A number of assumptions and linkages underlying the way expected credit losses had been implemented prior to the pandemic might no longer hold in an environment affected by a pandemic or similar macroeconomic event. Entities should not have continued to apply their existing expected credit loss methodology mechanically. The accounting impact of relief measures on expected credit losses depended on the details of the arrangements. For example, the extension of payment holidays or a waiver of a breach of covenant to all borrowers in particular classes of financial instruments would not automatically result in all those instruments being viewed as having suffered a significant increase in credit risk. This would be the case even if a moratorium resulted in a loss for the lender (e.g., if interest payments were reduced or waived), if it was provided irrespective of the borrowers' individual circumstances and the extension of payment holidays was assessed to be modifications rather than derecognition of the financial instruments (see section 8 below).

In other situations, if relief measures were available only to those who met certain criteria, entities would need to carefully assess whether such criteria themselves might have indicated a significant increase in credit risk for the affected borrowers. For instance, a significant increase in credit risk was more likely to have occurred if a borrower applied for a relief measure which was available only to corporates which had suspended operations or individuals who had lost employment. Another example was if the relief, such as a deferral of loan payments, was offered to all participants in certain industries. This circumstance might indicate that borrowers in that industry were exposed to a higher risk of business failure and, thus, a higher probability of default as a class. In combination with other reasonable and supportable information, this was more likely to result in the classification of the related loans and other exposures in this portfolio, or a portion of them, into stage 2. The assessment of significant increase in credit risk is made irrespective of the fact that a concession is imposed by laws or regulations. Entities were also expected to exercise judgement, in light of all facts and circumstances, including the effect of government support, to determine if the respective loans were credit-impaired and were therefore classified as stage 3.

Regulators have stressed, in the context of the coronavirus epidemic, the need when assessing borrowers to differentiate a temporary liquidity need from a significant increase in credit risk and highlighted that there might have been very limited information available to make this determination at an individual borrower level. This means that lenders distinguished between obligors whose long-term credit risk was unlikely to be significantly affected by the pandemic from those who might be more permanently impacted. In light of the above, the 30 days past due backstop assumption might need to be rebutted in these circumstances (see section 6.2.2 above).

Entities whose models included payment holidays or waiver of a covenant breach as an automatic significant increase in credit risk triggers might have needed to include overlays to unwind the effects if they determined that the significant increase in credit risk trigger was not warranted in this situation. For retail loans, data would often not be available to determine whether a significant increase in credit risk had occurred for individual borrowers. For wholesale exposures, more information was generally available on individual obligors, although the significant increase in credit risk assessment would still have been difficult. A lender might consider that borrowers in certain industries (e.g., airlines, tourism and hospitality) were exposed to a higher risk of business failure and, thus, an increased probability of default.

When it was not practical to determine significant increase in credit risk on an individual basis, a collective approach to staging was considered (see section 6.5 above). This would also have been challenging. A possible method could have been to transfer to stage 2 a portion of those customers who had been given a payment holiday or a waiver of a covenant breach, whose probability of default was already close to the level that would trigger a significant increase in credit risk. Any approach would have required considerable judgement.

Where additional rounds of relief measures were extended to existing borrowers, the same considerations which were applicable to assessing the initial relief were also applicable in determining whether the additional relief constituted a significant increase in credit risk. If the extension of the relief measures was offered only to selected borrowers (e.g., upon individual requests), it might have been harder to conclude that a significant increase in credit risk had not occurred, as the need for additional relief might be in response to further deterioration in the borrower's financial position.

7.8.5 Disclosures

Given the level of uncertainty and the sensitivity of judgements and estimates, the disclosure of the key assumptions used, and judgements made in estimating expected credit losses, as well as the concentration of risk, liquidity risk and the impact of any relief measures, were important (see section 15 below and Chapter 50). Important disclosures would have included, for example, the values of the key macroeconomic inputs used in the multiple economic scenario analysis and the probability weights of these scenarios, as well as the assumptions used to determine how the different challenges for specific sectors and regions had been taken into account and the effect of any management overlays.

In addition, entities provided disclosures to allow users of financial statements to understand the nature of any material reliefs offered to their borrowers, including those enforced by governments, and how they had assessed whether they constituted forbearance, whether they resulted in a substantial modification of the contract, their effect on staging and the impact on the overall expected credit loss. Entities also disclosed any material form of government grant or government assistance received in accordance with IAS 20.

Entities also considered any guidance and expectations on disclosures of expected credit losses issued by prudential and securities regulators in their jurisdictions.

How we see it

The assessment of the impact of the coronavirus pandemic and recovery on expected credit losses required significant judgement, especially as it was not directly comparable with any recent similar events and the impact depended on government measures as much as the spread of the virus. Entities would have updated their macroeconomic scenarios and considered the use of top-down 'management overlays' to embed in the expected credit loss risks not otherwise fully captured by their models or to avoid overstating expected credit losses. Given the level of uncertainty and the sensitivity of judgements and estimates, disclosures of the key assumptions used and judgements made in estimating expected credit losses, as well as the impact of any relief measures, was important.

To promote consistency and enable comparability of the expected credit loss estimate in those instances, banks were expected to provide additional quantitative and qualitative disclosures. The disclosures banks presented included the following, where relevant:

- An explanation of the nature of the adjustments and how these were calculated for each material overlay and 'in' or 'post' model adjustment.
- The reasons for the adjustment and impact, specifically what risks it addressed, including whether it was made to incorporate scenarios that could not be modelled without undue cost or effort (for example, to incorporate the impact of certain forms of government support or to include the most recent macroeconomic information available), to address model limitations (for example, the fact that the model results were based on outdated correlations or assumptions), adjust the expected increase in delinquency currently concealed by moratoria or reflect increased sectorial idiosyncrasies.
- Quantitative analysis, including, as a minimum, the absolute size of the adjustment, the overall effect on the expected credit loss estimate resulting from it, especially if materially changed compared to the last year-end, and narrative to explain the movements and expectations on timing of withdrawal going forward. Alternatively, the impact could have been disclosed as a percentage of the overall expected credit loss.
- Allocation by product, business segment and type of overlay (model adjustments due to models working outside historical observations, uncertainty overlays, sector related overlays, etc.), highlighting possible offsetting effects between different types of overlays (for example, between an overlay applied for potential default suppression due to government support schemes and an overlay applied to adjust probability of defaults when models were working outside historical observations).

How we see it

A number of banks provided quantitative and qualitative information in respect of post-model adjustments and management overlays while others merely mentioned that total expected credit losses included these elements without providing further analysis. Disclosures provided were diverse, with some banks breaking down these elements into the segments/portfolios/products they related to, while others referred to them without providing a numerical analysis or merely providing a total. Given the significant size of the model adjustments and management overlays, we would expect increased transparency and granularity in the relevant disclosures and that such disclosures are sufficiently detailed and clear for the users of the financial statements to understand.

An example of disclosures dealing with the impact of the coronavirus pandemic on expected credit losses, methodology, critical estimates and judgements, how economic scenarios were reflected in expected credit loss calculations and management judgemental adjustments to the expected credit loss of a bank is illustrated in Practical example 7-1 below.

Credit risk [extract]

Measurement uncertainty and sensitivity analysis of ECL estimates

(Audited)

The recognition and measurement of ECL involves the use of significant judgement and estimation. We form multiple economic scenarios based on economic forecasts, apply these assumptions to credit risk models to estimate future credit losses, and probability weight the results to determine an unbiased ECL estimate.

Management judgemental adjustments are used to address late-breaking events, data and model limitations, model deficiencies and expert credit judgements.

Amid a deterioration in the economic and geopolitical environment, management judgements and estimates continued to be subject to a high degree of uncertainty in relation to assessing economic scenarios for impairment allowances in 2022.

Inflation, economic contraction and high interest rates, combined with an unstable geopolitical environment and the effects of global supply chain disruption, contributed to elevated levels of uncertainty during the year.

At 31 December 2022, as a result of this uncertainty, additional stage 1 and 2 impairment allowances were recognised. Management continued to reflect a degree of caution both in the selection of economic scenarios and their weightings, and in the use of management judgemental adjustments, described in more detail below.

At 31 December 2022, there was a reduction in management judgemental adjustments compared with 31 December 2021. Adjustments related to Covid-19 and for sector-specific risks were reduced as scenarios and modelled outcomes better reflected the key risks at 31 December 2022.

...

Description of economic scenarios

The economic assumptions presented in this section have been formed by HSBC with reference to external forecasts and estimates, specifically for the purpose of calculating ECL.

Economic forecasts in the Central scenario remain subject to a high degree of uncertainty. Upside and Downside scenarios are constructed so that they encompass the potential crystallisation of a number of key macro-financial risks.

At the end of 2022, risks to the economic outlook included the persistence of high inflation and its consequences on monetary policy. Rapid changes to public policy also increased forecast uncertainty.

In Asia, the removal of Chinese Covid-19-related public health restrictions presents a key source of potential upside risk, but with significant near-term uncertainty relating to a subsequent surge of infections. This policy change could also have global implications.

In Europe, risks relating to energy pricing and supply security remain significant. Geopolitical risks also remain significant and include the possibility of a prolonged and escalating Russia-Ukraine war, continued differences between the US and other countries with China over a range of economic and strategic issues, and the evolution of the UK's relationship with the EU.

Economic forecasts for our main markets deteriorated in the fourth quarter as GDP growth slowed. In North America and Europe, high inflation and rising interest rates have reduced real household incomes and raised business costs, dampening consumption and investment and lowering growth expectations. The effects of higher interest rate expectations and lower growth are evident in asset price expectations, with house prices forecasts, in particular, significantly lower.

In Asia, forecasts for Hong Kong and mainland China were cut following weaker than expected third-quarter GDP growth, and due to China's adherence to a stringent pandemic-related public health policy response for the majority of the year. While China made an abrupt reversal of the policy in December and GDP is expected to recover in 2023, there remains a very high degree of uncertainty to both the upside and downside, and consensus forecasts have been slow to adjust. The increased uncertainty over China's lifting of the restrictions has been reflected in management's assessment of scenario probabilities.

...

Scenario weighting

In reviewing the economic conjuncture, the level of risk and uncertainty, management has considered both global and country-specific factors. This has led management to assign scenario probabilities that are tailored to its view of uncertainty in individual markets.

Key consideration around uncertainty attached to the Central scenario projections focused on:

- the progression of the Covid-19 pandemic in Asian countries, and the announcement of the removal of Covid-19-related measures and travel restrictions in mainland China and Hong Kong;
- further tightening of monetary policy, and the impact on borrowing costs in interest-rate sensitive sectors, such as housing;
- the risks to gas supply security in Europe, and the subsequent impact on inflation and commodity prices and growth; and
- the ongoing risks to global supply chains.

In mainland China and Hong Kong, the announcement of the relaxation of Covid-19-related measures and travel restrictions has led to increased uncertainty around the Central scenario projection. It was management's view that the easing of the policy could increase risks to the upside in the form of increased spending and travel. However, the continuing risks to the downside were also acknowledged, given the surge in Covid-19 infections and the potential for a new vaccine-resistant variant. This led management to assign a combined weighting of 75% to the consensus Upside and Central scenarios in both markets.

In the UK and US, the surge in price inflation and a squeeze on household real incomes have led to strong monetary policy responses from both central banks. Higher interest rates have increased recession risks and the prospects for outright decline in house prices. The UK faces additional challenges from the rise in energy prices and accompanying deterioration in the terms of trade. For Canada and Mexico, similar risk themes dominate, and the connectivity to the US has also been a key consideration. For the UK, the consensus Upside and Central scenarios had a combined weighting of 65%. In each of the other three markets, the combined weightings of the consensus Upside and Central scenarios were 75%.

In France, uncertainties around the outlook remain elevated due to high inflation and Europe's exposure to the Russia-Ukraine war through the economic costs incurred from the imposition of sanctions, trade disruption and energy dependence on Russia. The consensus Upside and Central scenarios had a combined weighting of 65%.

Management concluded that the outlook for the UAE was the least uncertain of all our key markets. It is benefiting from higher commodity prices and the revival in tourism and travel. The consensus Upside and Central scenarios had a combined weighting of 75%.

...

Critical estimates and judgements

The calculation of ECL under IFRS 9 involves significant judgements, assumptions and estimates. The level of estimation uncertainty and judgement has remained elevated since 31 December 2021, including judgements relating to:

- the selection and weighting of economic scenarios, given rapidly changing economic conditions and a wide dispersion of economic forecasts. There is judgement in making assumptions about the effects of inflation and interest rates, global growth, supply chain disruption; and
- estimating the economic effects of those scenarios on ECL, particularly as the historical relationship between macroeconomic variables and defaults might not reflect the dynamics of current macroeconomic conditions.

How economic scenarios are reflected in ECL calculations

Models are used to reflect economic scenarios on ECL estimates. As described above, modelled assumptions and linkages based on historical information could not alone produce relevant information under the conditions experienced in 2022, and management judgemental adjustments were still required to support modelled outcomes.

We have developed globally consistent methodologies for the application of forward economic guidance into the calculation of ECL for wholesale and retail credit risk. These standard approaches are described below, followed by the management judgemental adjustments made, including those to reflect the circumstances experienced in 2022.

For our wholesale portfolios, a global methodology is used for the estimation of the term structure of probability of default ('PD') and loss given default ('LGD'). For PDs, we consider the correlation of forward economic guidance to default rates for a particular industry in a country. For LGD calculations, we consider the correlation of forward economic guidance to collateral values and realisation rates for a particular country and industry. PDs and LGDs are estimated for the entire term structure of each instrument.

For impaired loans, LGD estimates take into account independent recovery valuations provided by external consultants where available or internal forecasts corresponding to anticipated economic conditions and individual company conditions. In estimating the ECL on impaired loans that are individually considered not to be significant, we incorporate the forward economic guidance proportionate to the probability-weighted outcome and the Central scenario outcome of the performing population.

For our retail portfolios, the impact of economic scenarios on PD is modelled at a portfolio level. Historical relationships between observed default rates and macroeconomic variables are integrated into IFRS 9 ECL estimates by using economic response models.

The impact of these scenarios on PD is modelled over a period equal to the remaining maturity of the underlying asset or assets. The impact on LGD is modelled for mortgage portfolios by forecasting future loan-to-value profiles for the remaining maturity of the asset by using national level forecasts of the house price index and applying the corresponding LGD expectation.

These models are based largely on historical observations and correlations with default rates. Management judgemental adjustments are described below.

Management judgemental adjustments

In the context of IFRS 9, management judgemental adjustments are typically short-term increases or decreases to the ECL at either a customer, segment or portfolio level to account for late-breaking events, model and data limitations and deficiencies, and expert credit judgement applied following management review and challenge.

This includes refining model inputs and outputs and using adjustments to ECL based on management judgement and higher-level quantitative analysis for impacts that are difficult to model.

The effects of management judgemental adjustments are considered for both balances and ECL when determining whether or not a significant increase in credit risk has occurred and is allocated to a stage where appropriate. This is in accordance with the internal adjustments framework.

Management judgemental adjustments are reviewed under the governance process for IFRS 9 (as detailed in the section 'Credit risk management' on page 145). Review and challenge focuses on the rationale and quantum of the adjustments with a further review carried out by the second line of defence where significant. For some management judgemental adjustments, internal frameworks establish the conditions under which these adjustments should no longer be required and as such are considered as part of the governance process. This internal governance process allows management judgemental adjustments to be reviewed regularly and, where possible, to reduce the reliance on these through model recalibration or redevelopment, as appropriate.

The drivers of management judgemental adjustments continue to evolve with the economic environment and as new risks emerge.

At 31 December 2022, there was a \$0.9bn reduction in management judgemental adjustments compared with 31 December 2021.

Adjustments related to Covid-19 and for sector-specific risks were reduced as scenarios and modelled outcomes better reflected the key risks at 31 December 2022.

...

Another example of disclosure dealing with the impact of the coronavirus pandemic on expected credit losses of a corporate is illustrated in Practical example 7-2 below.

Practical example 7-2: Centrica plc (2021)

United Kingdom

Annual Report and Accounts 2021 [extract]

Notes to the Financial Statements [extract]

3. Critical accounting judgements and key sources of estimation uncertainty [extract]

Credit provisions for trade and other receivables

The economic effects of the significant increase in wholesale gas and electricity costs, and resultant increase in consumer tariffs alongside wider inflationary pressures as well as the ongoing effects of the COVID-19 pandemic and cost of living pressures have impacted the ability of the Group's customers to pay amounts due. The level of estimation uncertainty in determining the credit provisions required for customers in different sectors and geographies continues to be raised.

The methodology for determining provisions for credit losses on trade and other receivables and the level of such provision, along with associated sensitivities, are set out in note 17. Although the provisions recognised are considered appropriate, the use of different assumptions or changes in economic conditions could lead to movements in the provisions and therefore impact the Group Income Statement.

17. Trade and other receivables, and contract-related assets

Sensitivity to changes in assumptions

Typically, the most significant assumption included within the expected credit loss provisioning model that gives rise to estimation uncertainty is that future performance will be reflective of past performance and that there will be no significant change in the payment profile or recovery rates within each identified group of receivables. To address this risk, the Group reviews and updates default rates, by group, on a regular basis to ensure they incorporate the most up to date assumptions along with forward-looking information where available and relevant. The Group also considers regulatory changes and customer segment specific factors that may have an impact, now or in the future, on the recoverability of the balance.

The specific consideration of forward-looking information in the impairment model does not usually give rise to significant changes in the levels of credit losses. However, inflationary pressures, increasing wholesale gas and electricity costs and the impacts of the global COVID-19 pandemic, continue to cause uncertainty in economic outlook. The economic recovery remains vulnerable and there remains a level of estimation uncertainty inherent in determining credit loss provisions for the Group's trade receivables.

Where customers experience difficulties in settling balances, the increased ageing of these amounts results in an increase in provisions held in respect of them under the provision matrix approach employed. The Group has also considered changes in customer payment patterns, the specific circumstances of the customers and the economic impacts of the factors identified above, on the sectors in which they operate. Whilst economic recovery is expected, a level of unpredictability remains apparent.

The Group has considered macroeconomic forecasts in determining the level of provisions for credit losses. Customers are facing increases to their cost of living, including increased energy bills, higher inflation and higher interest rates. Support received under COVID-19 assistance programmes has now been withdrawn. Unbilled energy income is more susceptible to credit risk from such forward-looking factors due to the length of time between the balance sheet date and collection of the amounts in cash. The Group considers that future economic growth remains modest.

During 2021 the Group recognised impairment charges of £116 million (2020: £195 million) in respect of financial assets, representing 0.8% of Group revenue (2020: 1.6%) and 0.6% of Group revenue from business performance (2020: 1.3%). The lower impairment charges in 2021 are driven by a reversion to a normalised level of bad debt charges. The prior year included a £30 million macroeconomic uplift. As described above, the majority of the Group's credit exposure arises in respect of downstream energy receivables in British Gas Energy and Centrica Business Services. Credit losses in respect of these assets amounted to £104 million (2020: £179 million). This represents 1.1% (2020: 2.2%) of total UK downstream energy supply revenue from these segments of £9,162 million (2020: £8,262 million). Further details of segmental revenue are provided in note 4.

...

7.9 Accounting for climate change

Climate change may affect an entity's assessment of expected credit losses, potentially leading to higher allowances for expected credit losses. The longer the term of the exposures and the greater the extent to which the counterparty is likely to be affected by climate change, the greater this effect is likely to be. Moreover, there is also the risk of climate change related rare shock events that needs to be taken into account, e.g., severe drought or heavy rainfall causing severe flooding, potentially resulting in damage to crops and homes, rising food prices and driving individuals and businesses into financial difficulties (see section 5.6.3 above) which could occur in the short term.

IFRS 9 requires use of forward-looking information to recognise expected credit losses. There is a variety of increasingly possible adverse future climate risk economic scenarios that could impact the probability of borrowers defaulting and the extent of losses that lenders may incur in the event of default. Climate risks are broadly categorised into physical and transition risks:

- Physical risks include the risk of loss due to specific weather events (such as storms or wildfires) and due to longer-term changes in weather trends (such as rising sea levels). Physical risks can impact the creditworthiness of borrowers due to business interruption, impacts on economic strength, asset values and unemployment.
- Transition risks relate to the risk of financial loss due to the economic transition toward a more sustainable economy. Transition risks could also result in a rapid deterioration of credit quality in sectors and/or countries affected, particularly if policy changes are radical or quickly implemented, and these factors are considered in a borrower's ability to repay and service debt.

From a credit risk perspective, physical and transition risks related to climate change could potentially impact:

- Probability of default affects staging of exposures and the measurement of expected credit loss allowances. Historical correlations that predict defaults may no longer be relevant. Methods for risk rating customers may, therefore, need to be updated as new financial and non-financial metrics capturing the impacts of climate change are made available. The impact of regulatory actions should also be considered.
- Loss given default affects the ultimate measurement of the expected credit loss allowance. Physical and transition risks may affect collateral values, for example, on mortgage loans, and lead to entities employing different collection strategies for distressed debt.
- Entities may make use of judgemental in-model or post-model adjustments to incorporate climate risks into their expected credit loss allowances, particularly in the short term due to data and model limitations. Enhanced governance processes will be required to support these judgements.
- Entities may need to incorporate climate risk factors into their macroeconomic scenarios and forward-looking information. The impact of climate risks on these scenarios is likely to be greater, the longer the duration of the underlying exposures and the greater an entity's exposure is to vulnerable sectors or geographies.
- Climate risk is likely to increase concentration risk exposures in vulnerable sectors or geographies. Sectors like agriculture and insurance may be particularly vulnerable to physical risks. For example, mining and oil and gas may be particularly exposed to transition risk. Some geographies such as those at or close to sea level or exposed to drought or flooding may be particularly exposed to physical risks. Entities will need to consider high risk sectors, industries, portfolios or geographies which require a collective staging assessment, e.g., high risk industries for climate change, mortgages in high flood-risk area and loans to the energy sector. Also, changes in risk concentrations may affect the modelling of expected credit loss allowances and the disclosure of credit risk concentrations.

Entities, particularly those with large credit risk exposures like banks, are in various stages of integrating climate risks into their risk frameworks, and there exist several challenges in this regard:

- Climate-related risks are uncertain, non-linear and pervasive.
- There are multiple projections and scenarios available to understand the size and impact of climate risk, but limited projections for economic and financial effects.
- Data and projections available are not always comparable, given divergence in taxonomies and standards globally.
- Entities need to collect new types of data on their customers and put in place new processes and governance.
- Identifying the right metrics to measure climate risk exposure can be challenging.
- Clarity or consensus on incorporating climate scenario analysis into risk assessments is still emerging.

This is an area which is likely to develop as the increased publication of sustainability reports will result in more data being available for use in ECL modelling. This is an area which attracts the attention of regulators and is likely to continue to do so. Regulators are also focussing on the connectivity between accounting and sustainability standards.

Practical example 7-3 shows how National Australia Bank Limited considered its exposure to climate risks as part of its credit risk assessment in its 2023 annual financial statements. In this example, the exposure to environmental, social and governance risks have been captured as part of a forward-looking adjustment.

Practical example 7-3: National Australia Bank Limited (2023)**Australia****ANNUAL FINANCIAL REPORT 2023 [extract]****NOTES TO THE FINANCIAL STATEMENTS [extract]****NOTE 19 FINANCIAL RISK MANAGEMENT [extract]****Credit risk [extract]****ESG risks**

The Group is exposed to ESG and other emerging risks. The following items are examples of how these risks may impact the Group:

- Increases in the frequency and severity of climatic events could impact customers' ability to service their loans or the value of the collateral held to secure the loans.
- Action taken by governments, regulators and society more generally, to transition to a low-carbon economy, could impact the ability of some customers to generate long-term returns in a sustainable way or lead to certain assets being stranded in the future.
- Failure to comply with environmental and social legislation (emerging and current) may impact customers' ability to generate sustainable returns and service their loans.
- If in future customers don't hold appropriate levels of insurance for physical assets against certain risks, this may impact the value the Group can recover in the event of certain natural disasters.

The Group considers these risks as part of the credit risk assessment and due diligence process before relevant customers are granted credit and for new product development. The Group also manages its total credit portfolio within established risk appetite and limits, particularly for specific industries or regions that are more exposed to these types of risks. In addition, the Group may recognise FLAs to the provision for credit impairment for the impact of adverse climate events. In the 2022 financial year, the Group recognised a FLA of \$14 million for the potential impact of the Lismore floods (2023: nil).

Practical example 7-4 shows how ABN AMRO Bank N.V. accounted for the potential transition risk by including a management overlay in the ECL calculation.

Practical example 7-4: ABN AMRO Bank N.V. (2023)**Netherlands****INTEGRATED ANNUAL REPORT 2023 [extract]****Risk, funding & capital [extract]****Risk management [extract]****Credit risk review [extract]****Individual and collective loan impairment allowances and management overlays [extract]**

...

During 2023, management overlays decreased to a total of EUR 260 million (31 December 2021: EUR 328 million). Overlays were mainly in place for risks in the corporate loans portfolio and comprised the following items:

- A management overlay of EUR 86 million (31 December 2022: EUR 123 million) that is applied for the geopolitical effects that are not fully captured by the latest projections in our macroeconomic scenarios (previously: overlay for the war in Ukraine)
- To cover anticipated additional risk costs relating to the wind-down of portfolios an overlay of EUR 31 million is in place. As the wind-down of the CIB non-core portfolio was completed this overlay was lowered in 2023 (31 December 2022: EUR 61 million)
- A new overlay of EUR 25 million was introduced for climate transition risk, following an update of the climate and environmental risk materiality assessment
- The overlay that was formed for the potential impact of the government's nitrogen reducing measures on clients in livestock farming businesses in the Netherlands amounting to EUR 35 million (31 December 2022: EUR 34 million)

...

In its 2023 Annual report, UBS Group AG disclosed the impact of sustainability and climate risk on the measurement of ECL. As shown in Practical example 7-5, while the impact was not material, the reasons for this outcome were disclosed.

Practical example 7-5: UBS Group AG (2023)	Switzerland
Annual Report 2023 [extract] 5 Financial statements [extract] Consolidated financial statements [extract] UBS Group AG consolidated financial statements [extract] Notes to the UBS Group AG consolidated financial statements [extract] Additional information [extract] Note 20 Expected credit loss measurement [extract] f) Sensitivity information [extract]	
<p>Sustainability and climate risk</p> <p>Sustainability and climate risk may negatively affect clients or portfolios due to direct or indirect transition costs, or exposure to physical risks in locations likely to be impacted by climate change. Such effects could lead to a deterioration in credit worthiness, which in turn would have an impact on ECLs.</p> <p>While some macroeconomic indicators used in the current PD models could be influenced by climate change, UBS currently does not use a specific sustainability and climate risk scenario in addition to the typically four general economic scenarios applied to derive the weighted-average ECL. The rationale for the approach at this point in time is the significance of model risks and challenges in calibration and probability weight assessment given the paucity of data.</p> <p>Instead, UBS focuses on the process of vetting clients and business transactions and takes individual actions, where transition risk is deemed to be a significant driver of a counterparty's credit worthiness. This review process may lead to a downward revision of the counterparty's credit rating, or the adoption of risk mitigating actions, and hence affect the individual contribution to ECLs.</p> <p>At the portfolio level, UBS has started to use stress loss assumptions to assess the extent to which sustainability and climate risk may affect the quality of the loans extended to small and medium-sized entities, large corporate clients and financial institutions. Initial tests were based on a set of assumptions presented by external parties (such as the Bank of England) and complemented by internally derived climate pathway scenarios. Such analysis undertaken during 2022 and reassessed during 2023 concluded that the counterparties are not expected to be significantly impacted by physical or transition risks, mainly as there are no material risk concentrations in high-risk sectors. The analysis of the corporate loan book has also shown that any potential significant impacts from transition costs or physical risks would materialize over a time horizon that exceeds in most cases the contractual lifetime of the underlying assets. Based on current information on regulatory developments, this would also apply to the portfolio of private clients' mortgages and real estate financing, given the long lead times for investments in upgrading housing stock.</p> <p>As a result of the aforementioned factors, it was assessed that the magnitude of any impact of sustainability and climate risk on the weighted-average ECL would not be material as of 31 December 2023. Therefore, no specific post-model adjustment was made in this regard.</p> <p>...</p>	

In its 2023 Annual report NatWest Group plc disclosed it was including climate related assumptions into its macroeconomic model and quantified an ECL impact.

Practical example 7-6: NatWest Group plc (2023)	United Kingdom
2023 Annual Report and Accounts [extract] Risk and Capital Management [extract] Credit Risk [extract] Economic Loss Drivers [extract]	
<p>Climate transition</p> <p>During 2023, NatWest Group continued to align its financial planning process with the climate transition planning process. This included adding climate policy and technology related transition assumptions into NatWest Group's base case macroeconomic scenario used for financial planning and assessment of ECL in this IFRS 9 reporting period. This resulted in an increase in ECL of less than £1 million.</p> <p>...</p>	

It is important to note that the factors outlined here should be considered by any entity that holds financial assets that are in the scope of the IFRS 9 impairment requirements - this includes financial institutions, as well as corporates. For example, Practical example 7-6 discloses how Rolls-Royce plc considered the impact of potentially vulnerable sectors when estimating ECL.

Practical example 7-7: Rolls-Royce Holdings plc (2023)

United Kingdom

Annual Report 2023 [extract]**FINANCIAL STATEMENTS [extract]****Notes to the consolidated financial statements [extract]****1 Accounting policies [extract]****Climate change [extract]**

Recoverability of trade receivables and contract assets – The impact of climate-related matters could have an impact on the Group's customers in the future, especially those customers in the Civil Aerospace division. No material climate-related issues have arisen during the year that have impacted the assessment of the recoverability of receivables. The Group's expected credit loss (ECL) provision uses credit ratings which inherently will include the market's assessment of the climate change impact on credit risk of the counter parties. Given the maturity time of trade receivables and the majority of contract assets, climate change is unlikely to cause a material increase on counter party credit risk in that time.

...

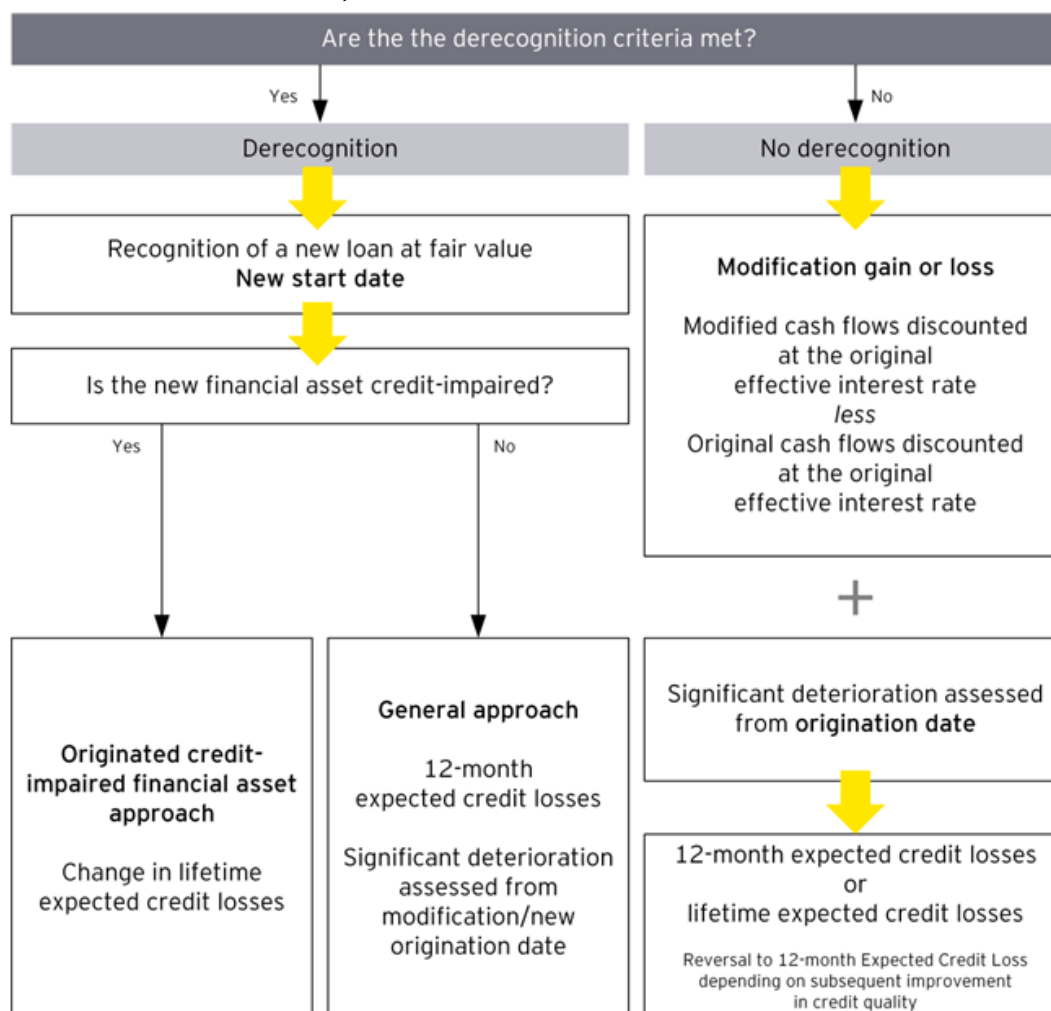

How we see it

The effect of climate risk on an entity's expected credit loss calculations is likely to be greater the longer the duration of the underlying exposures and the greater the entity's exposure to vulnerable sectors or geographies, although physical risks may also lead to short term exposures. Given the judgemental nature of incorporating climate risks into expected credit loss calculations, it is important that entities establish strong governance processes to support material judgements that they make in this regard, and that there are enhanced disclosures made about the risks and the impact of significant judgements and estimation uncertainty.

8 Modified financial assets

If the contractual cash flows on a financial asset are renegotiated or modified, the holder needs to assess whether the financial asset is derecognised (see Chapter 48 and Chapter 46 for further details on modification and derecognition). In summary, an entity should derecognise a financial asset if the cash flows are extinguished or if the terms of the instrument have substantially changed. This applies to all modifications whether they result from commercial or other reasons that are unrelated to credit risk.

Figure 8-1: Application of the derecognition and modification requirements and their interaction with expected credit loss assessment

8.1 Accounting treatment if modified financial assets are derecognised

In some circumstances, the renegotiation or modification of the contractual cash flows of a financial asset can lead to the derecognition of the existing financial asset and subsequently, the recognition of a new financial asset. [IFRS 9.B5.5.25]. This means that the entity is starting fresh and the date of the modification will also be the date of initial recognition of the new financial asset at its fair value. Typically, the entity will recognise a loss allowance based on 12-month expected credit losses at each reporting date until the requirements for the recognition of lifetime expected credit losses are met. However, in what IFRS 9 describes as 'some unusual circumstances' following a modification that results in derecognition of the original financial asset, there may be evidence that the new financial asset is credit-impaired on initial recognition (see section 3.3 above). Thus, the financial asset is recognised as an originated credit-impaired financial asset. [IFRS 9.B5.5.26].

8.2 Accounting treatment if modified financial assets are not derecognised

In other circumstances, the renegotiation or modification of the contractual cash flows of a financial asset does not lead to the derecognition of the existing financial asset under IFRS 9. In such situations, the entity will:

- Continue with its current accounting treatment for the existing asset that has been modified.
- Recognise a modification gain or loss in profit or loss by recalculating the gross carrying amount of the financial asset as the present value of the renegotiated or modified contractual cash flows, discounted at the financial asset's original effective interest rate (or the credit-adjusted effective interest rate for purchased or originated credit-impaired financial assets). Any costs or fees incurred adjust the carrying amount of the modified financial asset and are amortised over the remaining term of the modified financial asset (see section 3.1 above). *[IFRS 9.5.4.3, IFRS 9 Appendix A]*.
- Assess whether there has been a significant increase in the credit risk of the financial instrument, by comparing the risk of a default occurring at the reporting date (based on the modified contractual terms) and the risk of a default occurring at initial recognition (based on the original, unmodified contractual terms). A financial asset that has been renegotiated or modified is not automatically considered to have lower credit risk. The assessment considers the credit risk over the expected life of the asset based on historical and forward-looking information, including information about the circumstances that led to the modification. Evidence that the criteria for the recognition of lifetime expected credit losses are subsequently no longer met may include a history of up-to-date and timely payment in subsequent periods. This means a minimum period of observation will often be necessary before a financial asset may qualify to return to stage 1. *[IFRS 9.5.5.12, IFRS 9.B5.5.27]*.
- Make the appropriate quantitative and qualitative disclosures required for renegotiated or modified assets to enable users of financial statements to understand the nature and effect of such modifications (including the effect on the measurement of expected credit losses) and how the entity monitors its assets that have been modified (see section 15 below and Chapter 50). *[IFRS 7.35F(f), IFRS 7.B8B, IFRS 7.35J]*.

If a financial asset is modified as part of forbearance and the modification results in forgiveness of part of the contractual cash flows, the entity might need to consider whether any portion of the financial asset should be written off before the modification takes place.

The following Illustration has been adapted from Example 11 of the Illustrative Examples to IFRS 9 to illustrate the accounting treatment of a loan that is modified. It is noted that it does not consider whether any of the contractual cash flows are written off, as a partial derecognition. *[IFRS 9.IE Example 11, IFRS 9.IE66-IE73]*.

Illustration 8-1: Modification of contractual cash flows

Bank A originates a five-year loan that requires the repayment of the outstanding contractual amount in full at maturity. Its contractual par amount is CU1,000 with an interest rate of 5%, payable annually. The effective interest rate is 5%. At the end of the first reporting period in Year 1, Bank A recognises a loss allowance at an amount equal to 12-month expected credit losses because there has not been a significant increase in credit risk since initial recognition. A loss allowance balance of CU20 is recognised. In Year 2, Bank A determines that the credit risk on the loan has increased significantly since initial recognition. As a result, Bank A recognises lifetime expected credit losses on the loan. The loss allowance balance is CU150 at the end of year 2.

At the end of Year 3, following significant financial difficulty of the borrower, Bank A modifies the contractual cash flows on the loan. It forgoes interest payments beyond year 3 until maturity and extends the contractual term of the loan by one year so that the remaining term at the date of the modification is three years. The modification does not result in the derecognition of the loan by Bank A.

As a result of that modification, Bank A recalculates the gross carrying amount of the financial asset as the present value of the modified contractual cash flows discounted at the loan's original effective interest rate of 5%. The difference between this recalculated gross carrying amount and the gross carrying amount before the modification is recognised as a modification gain or loss. Bank A recognises the modification loss (calculated as CU136) against the gross carrying amount of the loan, reducing it to CU864, and a modification loss of CU136 in profit or loss.

Bank A also remeasures the loss allowance, taking into account the modified contractual cash flows and evaluates whether the loss allowance for the loan continues to be measured at an amount equal to lifetime expected credit losses. Bank A compares the current credit risk (taking into consideration the modified cash flows) to the credit risk (on the original unmodified cash flows) at initial recognition. Bank A determines that the loan is not credit-impaired at the reporting date but that credit risk has still significantly increased compared to the credit risk at initial recognition. It continues to measure the loss allowance at an amount equal to the lifetime expected credit loss, which is CU110 at the reporting date.

At each subsequent reporting date, Bank A continues to evaluate whether there has been a significant increase in credit risk by comparing the loan's credit risk at initial recognition (based on the original, unmodified cash flows) with the credit risk at the reporting date (based on the modified cash flows).

Two reporting periods after the loan modification (Year 5), the borrower has outperformed its business plan significantly compared to the expectations at the modification date. In addition, the outlook for the business is more positive than previously envisaged. An assessment of all reasonable and supportable information that is available without undue cost or effort indicates that the overall credit risk on the loan has decreased and that the risk of a default occurring over the expected life of the loan has decreased, so Bank A adjusts the borrower's internal credit rating at the end of the reporting period.

Given the positive overall development, Bank A re-assesses the situation and concludes that the credit risk of the loan has decreased and there is no longer a significant increase in credit risk since initial recognition. As a result, Bank A once again measures the loss allowance at an amount equal to 12-month expected credit losses.

Year	Beginning gross carrying amount CU	Impairment (loss)/gain CU	Modification (loss)/gain CU	Interest revenue CU	Cash flows CU	Ending gross carrying amount CU	Loss allowance CU	Ending amortised cost amount CU
	A	B	C	D Gross: A × 5%	E	F = A + C + D - E	G	H = F - G
1	1,000	(20)		50	50	1,000	20	980
2	1,000	(130)		50	50	1,000	150	850
3	1,000	40	(136)	50	50	864	110	754
4	864	24		43		907	86	821
5	907	72		45		952	14	938
6	952	14		48	1,000	0	0	0

Frequently asked questions

Question 8-1: How to determine the expected credit losses in respect of a modified financial asset if the modification had not resulted in a derecognition but the modified cash flows have been renegotiated in such a way as to represent the cash flows which the lender expects the borrower can repay?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 22 April 2015 - Agenda paper no. 8)

At its meeting on 22 April 2015, the IFRS Transition Resource Group for Impairment of Financial Instruments members (see section 1.4 above) noted that IFRS 9 is clear that an entity is required to calculate a new gross carrying amount and the gain or loss on modification taken to profit or loss is based on the renegotiated or modified contractual cash flows and excludes expected credit losses unless it is a purchased or originated credit-impaired financial asset. [IFRS 9.5.4.3, IFRS 9 Appendix A]. Consequently, an entity must calculate the gain or loss on modification as a first step before going on to consider the revised expected credit loss allowance required on the modified financial asset. Thereafter, the entity is required to continue to apply the impairment requirements to the modified financial asset in the same way as it would for other unmodified financial instruments, taking into account the revised contractual terms. [IFRS 9.5.5.12]. The revised expected credit loss cannot be assumed to be nil as, in accordance with IFRS 9.5.5.18, an entity is required to consider the possibility that a credit loss occurs, even if the likelihood of that credit loss occurring is very low. [IFRS 9.5.5.18].

The IFRS Transition Resource Group for Impairment of Financial Instruments also discussed the appropriate presentation and disclosure requirements pertaining to modifications. These are discussed further in Chapter 50.

How we see it

If an entity has no reasonable expectations of recovering a portion of the financial asset, which is subsequently forgiven, then this amount is arguably written off, as a partial derecognition. The gross carrying amount would be reduced directly before a modification gain or loss is calculated. This would mean that the loss will be recorded as an impairment loss, rather than as a loss on modification, and presented differently in the profit or loss account. In practice, it will often be difficult to disentangle the effects of modification and write-off, as some forgone cash flows may be compensated for by a higher interest rate applied to the remaining contractual amounts due.

9 Financial assets measured at fair value through other comprehensive income

For financial assets measured at fair value through other comprehensive income (see Chapter 44), the expected credit losses do not reduce the carrying amount of the financial assets in the statement of financial position, which remains at fair value. Instead, an amount equal to the allowance that would arise if the asset was measured at amortised cost is recognised in other comprehensive income as the 'accumulated impairment amount'. [IFRS 9.4.1.2A, IFRS 9.5.5.2, IFRS 9 Appendix A].

9.1 Accounting treatment for debt instruments measured at fair value through other comprehensive income

The accounting treatment and journal entries for debt instruments measured at fair value through other comprehensive income are shown in the following Illustration, based on Illustrative Example 13 in the Illustrative Examples to IFRS 9. [IFRS 9.IE Example 13, IFRS 9.IE78, IFRS 9.IE79, IFRS 9.IE80, IFRS 9.IE81].

Illustration 9-1: Debt instrument measured at fair value through other comprehensive income

An entity purchases a debt instrument with a fair value of CU1,000 on 15 December 20X2 and measures the debt instrument at fair value through other comprehensive income. The instrument has an interest rate of 5% over the contractual term of 10 years, and has a 5% effective interest rate. At initial recognition the entity determines that the asset is not purchased or originated credit-impaired.

Dr	Financial asset - fair value through other comprehensive income	CU1,000	
	Cr	Cash	CU1,000

To recognise the debt instrument measured at its fair value

On 31 December 20X2 (the reporting date), the fair value of the debt instrument has decreased to CU950 as a result of changes in market interest rates. The entity determines that there has not been a significant increase in credit risk since initial recognition and that expected credit losses should be measured at an amount equal to 12-month expected credit losses, which amounts to CU30. For simplicity, journal entries for the receipt of interest revenue are not provided.

Dr	Impairment loss (profit or loss)	CU30	
Dr	Other comprehensive income ^(a)	CU20	
	Cr	Financial asset - fair value through other comprehensive income	CU50

To recognise 12-month expected credit losses and other fair value changes on the debt instrument

(a) The cumulative loss in other comprehensive income at the reporting date was CU20. That amount consists of the total fair value change of CU50 (i.e., CU1,000 - CU950) offset by the change in the accumulated impairment amount representing 12-month expected credit losses that was recognised (CU30).

Disclosure would be provided about the accumulated impairment amount of CU30.

On 1 January 20X3, the entity decides to sell the debt instrument for CU950, which is its fair value at that date.

Dr	Cash	CU950	
	Cr	Financial asset - fair value through other comprehensive income	CU950
Dr	Loss (profit or loss)	CU20	
	Cr	Other comprehensive income	CU20

To derecognise the fair value through other comprehensive income asset and recycle amounts accumulated in other comprehensive income to profit or loss, i.e., CU20

This means that in contrast to financial assets measured at amortised cost, there is no separate allowance but, instead, impairment gains or losses are accounted for as an adjustment of the revaluation reserve accumulated in other comprehensive income, with a corresponding charge to profit or loss (which is then reflected in retained earnings). The tax implications of debt instruments measured at fair value through other comprehensive income is discussed further in Chapter 29.

As explained in section 7.3.1 above, IFRS 9 requires a derecognition gain or loss to be measured relative to the carrying amount at the date of derecognition. This necessitates an assessment and measurement of expected credit losses for that particular asset as at the date of derecognition.

9.2 Interaction between foreign currency translation, fair value hedge accounting and impairment

The above example is relatively straightforward. A more complicated one, based on a foreign currency denominated financial asset which is also the subject of an interest rate hedge, is provided below. It is based on Illustrative Example 14 in the Illustrative Examples to IFRS 9 but has been adjusted so as to include the effect of discounting in the measurement of expected credit losses (see section 5.7 above). [IFRS 9.IE82-IE102]. Note that we do not address the additional complexities that will arise from the consideration of taxation, including deferred tax. The tax accounting implications of debt instruments measured at fair value through other comprehensive income is discussed further in Chapter 29.

Illustration 9-2: Interaction between the fair value through other comprehensive income measurement category and foreign currency denomination, fair value hedge accounting and impairment

The example assumes the following fact pattern and that, on initial recognition, expected credit losses are included when measuring foreign exchange gains and losses (see section 7.3.1 above):

- An entity purchases a bond denominated in a foreign currency (FC) for its fair value of FC100,000 on 1 January 20X2.
- The bond is held within a business model whose objective is achieved by both collecting contractual cash flows and selling financial assets and has contractual cash flows which are solely payments of principal and interest on the principal amount outstanding. Therefore, the entity classifies the bond as measured at fair value through other comprehensive income.
- The bond has five years remaining to maturity and a fixed coupon of 5% over its contractual life on the contractual par amount of FC100,000.
- The entity hedges the bond for its interest rate related fair value risk. The fair value of the corresponding interest rate swap at the date of initial recognition is nil.
- On initial recognition, the bond has a 5% effective interest rate which results in a gross carrying amount that equals the fair value at initial recognition.
- The entity's functional currency is its local currency (LC).
- As at 1 January 20X2, the exchange rate is FC1 to LC1.
- At initial recognition, the entity determines that the bond is not purchased credit-impaired. The entity applies a 12-month probability of default for its impairment calculation and assumes that payment default occurs at the end of the reporting period (i.e., after 12 months). In particular, the entity estimates the probability of default over the next 12 months at 2% and the loss given default at FC60,000, resulting in an (undiscounted) expected cash shortfall of FC1,200. The discounted expected cash shortfall is FC1,143 at 5% effective interest rate (see the example below for the detailed calculation).
- For simplicity, amounts for interest revenue are not provided. It is assumed that interest accrued is received in the period. Differences of 1 in the calculations and reconciliations are due to rounding.

The entity hedges its risk exposures using the following risk management strategy:

- (a) For fixed interest rate risk (in FC) the entity decides to link its interest receipts in FC to current variable interest rates in FC. Consequently, the entity uses interest rate swaps denominated in FC under which it pays fixed interest and receives variable interest in FC.
- (b) For foreign exchange (FX) risk, the entity decides not to hedge against any variability in LC arising from changes in foreign exchange rates.

The entity designates the following hedging relationship: a fair value hedge of the bond in FC as the hedged item with changes in benchmark interest rate risk in FC as the hedged risk. The entity enters into a swap that pays fixed and receives variable interest in FC on the same day and designates the swap as the hedging instrument. The tenor of the swap matches that of the hedged item (i.e., five years). This example assumes that all qualifying criteria for hedge accounting are met (see IFRS 9.6.4.1). The description of the designation is solely for the purpose of understanding this example (i.e., it is not an example of the complete formal documentation required in accordance with IFRS 9.6.4.1).

This example assumes that no hedge ineffectiveness arises in the hedging relationship. This assumption is made in order to better focus on illustrating the accounting mechanics in a situation that entails measurement at fair value through other comprehensive income of a foreign currency financial instrument that is designated in a fair value hedge relationship, and also to focus on the recognition of impairment gains or losses on such an instrument.

The entity decided not to amortise the fair value hedge adjustment to profit or loss before the hedge ceases or the asset is credit-impaired. Consequently, in this example, there is no adjustment to the effective interest rate due to fair value hedge accounting. However, such an adjustment to the effective interest rate would at the latest be required when the entity ceases to apply hedge accounting or when the asset becomes credit-impaired, i.e., moved to stage 3. (See section 7.5 above).

Situation as per 1 January 20X2

The table below illustrates the amounts recognised in the financial statements as per 1 January 20X2, as well as the shadow amortised cost calculation for the bond, based on the fact pattern described above (debits are shown as positive numbers and credits as negative numbers):

Financial Statements			Shadow Calculation	
	FC	LC		
	Statement of financial position			
Bond (FV)	100,000	100,000	Gross carrying amount	100,000
Swap (FV)	-	-	Loss allowance	(1,143)
			Amortised cost	98,857
	Statement of profit or loss			
Impairment	1,143	1,143	FV hedge adjustment	-
FV hedge (bond)	-	-	Adjusted gross carrying amt.	100,000
FX gain/loss (bond)	-	-	Adjusted amortised cost	98,857
FV hedge (swap)	-	-		
FX gain/loss (swap)	-	-		
	Statement of other comprehensive income			
FV changes	-	-		
Impairment offset	(1,143)	(1,143)		
FV hedge adjustment	-	-		

As per 1 January 20X2, the entity recognises the bond and the swap at their initial fair values of LC100,000 and nil, respectively. The loss allowance of FC1,143 is recognised in profit or loss. The amount is calculated as the difference between all contractual cash flows that are due to the entity in accordance with the contract and all the cash flows that the entity expects to receive (i.e., all cash shortfalls), discounted at the original effective interest of 5%, and weighted by the probability of the scenario occurring. To keep the example simple, it is assumed that default on the bond occurs one year after the date of the initial recognition, at which point the recoverable amount of the bond is received. This means that in the case of a default the entity expects cash flows of FC45,000 (which is the principal of FC100,000 plus one year of interest of FC5,000 less the loss given default of FC60,000). The latter loss is discounted by the 5% effective interest rate and weighted by the 2% probability of default to arrive at the loss allowance. The table below shows the expected credit loss calculation:

1 January 20X2 (values in FC)	Year 1	Year 2	Year 3	Year 4	Year 5
Contractual cash flows	5,000	5,000	5,000	5,000	105,000
Expected cash flows	45,000				
Expected cash shortfalls	40,000	(5,000)	(5,000)	(5,000)	(105,000)
NPV at 5%	(57,143)				
Probability of default	2%				
Net present value (probability-weighted) - this is the expected credit loss	(1,143)				

In accordance with IFRS 7.16A, the loss allowance for financial assets measured at fair value through other comprehensive income is not presented separately as a reduction of the carrying amount of the financial asset. As a consequence, the offsetting entry to the impairment loss of LC1,143 is recorded in other comprehensive income in the same period.

Situation as at 31 December 20X2

As of 31 December 20X2 (the reporting date), the entity observes the following facts:

- The fair value of the bond has decreased from FC100,000 to FC96,370, mainly because of an increase in market interest rates.
- The fair value of the swap has increased to FC1,837.
- In addition, as at 31 December 20X2, the entity determines that there has been no change to the credit risk on the bond since initial recognition. The entity still estimates the probability of default over the next 12 months at 2% and the loss given default at FC60,000, resulting in an (undiscounted) expected shortfall of FC1,200.
- As at 31 December 20X2, the exchange rate is FC1 to LC1.4.

The table below illustrates the amounts recognised in the financial statements between 1 January 20X2 (after the entries for the impairment loss of FC1,143 at 1 January, shown above) and 31 December 20X2, as well as the shadow amortised cost calculation for the bond (debits are shown as positive numbers and credits as negative numbers):

	Financial Statements			Shadow Calculation	
	FC	LC		FC	LC
	Statement of financial position				
Bond (FV)	96,370	134,918	Gross carrying amount	100,000	140,000
Swap (FV)	1,837	2,572	Loss allowance	(1,143)	(1,600)
			Amortised cost	98,857	138,400
	Statement of profit or loss				
Impairment	-	-	FV hedge adjustment	(1,837)	(2,572)
FV hedge (bond)	1,837	2,572	Adjusted gross carrying amount	98,163	137,428
FX gain/loss (bond)		(39,543)	Adjusted amortised cost	97,020	135,828
FV hedge (swap)	(1,837)	(2,572)			
FX gain/loss (swap)	-	-			
	Statement of other comprehensive income				
FV changes	3,630	4,625			
Impairment offset	-	-			
FV hedge adjustment	(1,837)	(2,572)			

Because the entity has maintained the expected cash shortfall pattern and its probability of occurring, the change in estimate is just the effect of deferral by a year of the expected date of default, which exactly offsets the unwinding of the discount.

The bond is a monetary asset. Consequently, the entity recognises the changes arising from movements in foreign exchange rates in profit or loss in accordance with IAS 21.23(a) and IAS 21.28 and recognises other changes in accordance with IFRS 9. For the purposes of applying IAS 21.28, the asset is treated as an asset measured at amortised cost in the foreign currency.

The change in the fair value of the bond since 1 January 20X2 amounts to LC34,918 and is recognised as a fair value adjustment to the carrying amount of the bond on the entity's statement of financial position.

The gain of LC39,543 due to the changes in foreign exchange rates is recognised in profit or loss. It consists of the impact of the change in the exchange rates during 20X2:

- On the original gross carrying amount of the bond, amounting to LC40,000.
- Offset by the loss allowance of the bond, amounting to LC457 (i.e., the difference of FC1,143 translated at the exchange rate as at 1 January 20X2 of FC1 to LC1 and FC1,143 translated at the exchange rate as at 31 December 20X2 of FC1 to LC1.4).

The difference between the change in fair value (LC34,918) and the gain recognised in profit or loss that is due to the changes in foreign exchange rates (LC39,543) is recognised in other comprehensive income. That difference amounts to LC4,625.

A gain of LC2,572 (FC1,837) on the swap is recognised in profit or loss and, because it is assumed that there is no hedge ineffectiveness, this amount coincides with the loss on the hedged item. Illustrative Example 14 of IFRS 9 seems to suggest that the hedging gain or loss of a debt instrument at fair value through other comprehensive income is recycled from other comprehensive income in the same period but, since IFRS 9.6.5.8(b) requires the hedging gain or loss on the hedged item to be recognised in profit or loss and the offsetting entry is to other comprehensive income, this is not strictly 'recycling'.

Situation as at 31 December 20X3

As of 31 December 20X3 (the reporting date), the entity observes the following facts:

- The fair value of the bond has further decreased from FC96,370 to FC87,114.
- The fair value of the swap has increased to FC2,092.
- Based on adverse macroeconomic developments in the industry in which the bond issuer operates, the entity assumes a significant increase in credit risk since initial recognition, and recognises the lifetime expected credit loss for the bond.
- The entity updates its impairment estimate and now estimates the lifetime probability of default at 20% and the loss given default at FC48,500, resulting in (undiscounted) expected cash shortfalls of FC9,700. (For simplicity, this example assumes that payment default will happen on maturity when the entire face value becomes due).
- As at 31 December 20X3, the exchange rate is FC1 to LC1.25.

The table below illustrates the amounts recognised in the financial statements between 31 December 20X2 and 31 December 20X3, as well as the shadow amortised cost calculation for the bond (debits are shown as positive numbers and credits as negative numbers):

	Financial Statements			Shadow Calculation	
	FC	LC		FC	LC
	Statement of financial position				
Bond (FV)	87,114	108,893	Gross carrying amount	100,000	125,000
Swap (FV)	2,092	2,615	Loss allowance	(8,379)	(10,474)
			Amortised cost	91,621	114,526
	Statement of profit or loss				
Impairment	7,236	9,045	FV hedge adjustment	(2,092)	(2,615)
FV hedge (bond)	255	319	Adj. gross carrying amt.	97,908	122,385
FX gain/loss (bond)		14,553	Adj. amortised cost	89,529	111,911
FV hedge (swap)	(255)	(319)			
FX gain/loss (swap)		276			
	Statement of other comprehensive income				
FV changes	9,256	11,472			
Impairment offset	(7,236)	(9,045)			
FV hedge adjustment	(255)	(319)			

The table below illustrates the expected credit loss calculation:

31 December 20X2 (values in FC)	Year 3	Year 4	Year 5
Contractual cash flows	5,000	5,000	105,000
Expected cash flows	5,000	5,000	56,500
Expected cash shortfalls	-	-	(48,500)
NPV at 5.8%	(41,896)		
Probability of default	20%		
Net present value (probability-weighted)			
- this is the expected credit loss	(8,379)		

Again, the table above shows how the expected credit loss is calculated as the net present value of the cash shortfalls, i.e., the difference between contractual and expected cash flows on each relevant date. The offsetting entry of the impairment loss FC7,236 (LC9,045) is recorded in other comprehensive income in the same period.

The change in the fair value of the bond since 31 December 20X2 amounts to a decrease of LC26,026 and is recognised as a fair value adjustment to the carrying amount of the bond on the entity's statement of financial position.

The loss of LC14,553 due to the changes in foreign exchange rates is recognised in profit or loss. It consists of the impact of the change in the exchange rates during 20X2:

- On the original gross carrying amount of the bond, amounting to a loss of LC15,000.
- On the loss allowance of the bond, amounting to a gain of LC171.
- On the fair value hedge adjustment, amounting to a gain of LC276.

The difference between the change in fair value (decrease of LC26,026) and the loss recognised in profit or loss that is due to the changes in foreign exchange rates (LC14,553) is recognised in other comprehensive income.

A gain of LC319 (FC255) on the swap is recognised in profit or loss and, because it is assumed that there is no hedge ineffectiveness, this amount coincides with the loss on the hedged item.

Situation as at 1 January 20X4

On 1 January 20X4, the entity decides to sell the bond for FC87,114, which is its fair value at that date and also closes out the swap at its fair value. For simplicity, all amounts, including the foreign exchange rate, are assumed to be the same as at 31 December 20X3.

Upon derecognition, the entity reclassifies the cumulative amount recognised in other comprehensive income of LC3,018 (FC2,415) to profit or loss. This amount is equal to the difference between the fair value and the adjusted amortised cost amount of the bond, including the fair value hedge adjustment at the time of its derecognition. The table below presents a reconciliation of those amounts.

Reconciliation of loss on derecognition (values in LC) to cumulative other comprehensive income				
Fair value per 1 January 20X4	108,893			
Adjusted amortised cost per 1 January 20X4	111,911			
Loss	(3,018)			
	Cumulative other comprehensive income	1 January 20X2	31 December 20X2	31 December 20X3
FV changes	16,097	-	4,625	11,472
Impairment	(10,188)	(1,143)	-	(9,045)
FV hedge adjustment	(2,891)	-	(2,572)	(319)
Total other comprehensive income to be reclassified	3,018			

This table presents the amount that has not yet been recycled and, therefore, must be reclassified to profit or loss on derecognition.

10 Trade receivables, contract assets and lease receivables

IFRS 9 provides some operational simplifications for trade receivables, contract assets and lease receivables. These are the requirement or policy choice to apply the simplified approach that does not require entities to track changes in credit risk (see section 3.2 above) and the practical expedient to calculate expected credit losses on trade receivables using a provision matrix (see section 10.1 below).

10.1 Trade receivables and contract assets

It is a requirement for entities to apply the simplified approach for trade receivables or contract assets that do not contain a significant financing component. However, entities have a policy choice to apply either the general approach (see section 3.1 above) or the simplified approach separately to trade receivables and contract assets that do contain a significant financing component (see section 3.2 above). [IFRS 9.5.5.15(a)].

Also, entities are allowed to use practical expedients when measuring expected credit losses, as long as the approach reflects a probability-weighted outcome, the time value of money and reasonable and supportable information that is available without undue cost or effort at the reporting date about past events, current conditions and forecasts of future economic conditions. [IFRS 9.5.5.17, IFRS 9.B5.5.35]. One of the approaches suggested in IFRS 9 is the use of a provision matrix as a practical expedient for measuring expected credit losses on trade receivables. To calibrate the matrix, the entity would adjust its historical credit loss experience with forward-looking information: [IFRS 9.B5.5.35, IFRS 9.5.5.17]

Extract from IFRS 9

B5.5.35 An entity may use practical expedients when measuring expected credit losses if they are consistent with the principles in paragraph 5.5.17. An example of a practical expedient is the calculation of the expected credit losses on trade receivables using a provision matrix. The entity would use its historical credit loss experience (adjusted as appropriate in accordance with paragraphs B5.5.51-B5.5.52) for trade receivables to estimate the 12-month expected credit losses or the lifetime expected credit losses on the financial assets as relevant. A provision matrix might, for example, specify fixed provision rates depending on the number of days that a trade receivable is past due (for example, 1 per cent if not past due, 2 per cent if less than 30 days past due, 3 per cent if more than 30 days but less than 90 days past due, 20 per cent if 90-180 days past due etc). Depending on the diversity of its customer base, the entity would use appropriate groupings if its historical credit loss experience shows significantly different loss patterns for different customer segments. Examples of criteria that might be used to group assets include geographical region, product type, customer rating, collateral or trade credit insurance and type of customer (such as wholesale or retail).

In practice, many corporates use a provision matrix to calculate their current impairment allowances. However, in order to comply with the IFRS 9 requirements, corporates have needed to consider how current and forward-looking information might affect their customers' historical default rates and, consequently, how the information would affect their current expectations and estimates of expected credit losses. The use of the provision matrix is shown in the following Illustration. [IFRS 9.IE Example 12, IFRS 9.IE74, IFRS 9.IE75, IFRS 9.IE76, IFRS 9.IE77].

Illustration 10-1: Provision matrix

Company M, a manufacturer, has a portfolio of trade receivables of CU30 million in 20X2 and operates only in one geographical region. The customer base consists of a large number of small clients and the trade receivables are categorised by common risk characteristics that are representative of the customers' abilities to pay all amounts due in accordance with the contractual terms. The trade receivables do not have a significant financing component in accordance with IFRS 15. In accordance with IFRS 9.5.5.15, the loss allowance for such trade receivables is always measured at an amount equal to lifetime expected credit losses. To determine the expected credit losses for the portfolio, Company M uses a provision matrix. The provision matrix is based on its historical observed loss rates over the expected life of the trade receivables and is adjusted for forward-looking estimates. At every reporting date, the historical observed loss rates are updated and changes in the forward-looking estimates are analysed. In this case it is forecast that economic conditions will deteriorate over the next year.

On that basis, Company M estimates the following provision matrix:

	Current	1-30 days past due	31-60 days past due	61-90 days past due	More than 90 days past due
Loss rate	0.3%	1.6%	3.6%	6.6%	10.6%

The trade receivables from the large number of small customers amount to CU30 million and are measured using the provision matrix.

	Gross carrying amount	Lifetime expected credit loss allowance (Gross carrying amount × lifetime loss rate)
Current	CU15,000,000	CU45,000
1-30 days past due	CU7,500,000	CU120,000
31-60 days past due	CU4,000,000	CU144,000
61-90 days past due	CU2,500,000	CU165,000
More than 90 days past due	CU1,000,000	CU106,000
	CU30,000,000	CU580,000

It is noted that this example, like many in IFRS 9, ignores the need to consider explicitly the time value of money, presumably in this case because the effect is considered immaterial.

10.2 Lease receivables

For lease receivables, entities have a policy choice to apply either the general approach (see section 3.1 above) or the simplified approach (see section 3.2 above) separately to finance and operating lease receivables (see Chapter 24). [IFRS 9.5.5.15(b)].

When measuring expected credit losses for lease receivables, an entity:

- Uses the cash flows that are used in measuring the lease receivables in accordance with IFRS 16. [IFRS 9.B5.5.34].
- Discounts the expected credit losses using the same discount rate used in the measurement of the lease receivables in accordance with IFRS 16. [IFRS 9.B5.5.46].

There has been some discussion on whether the unguaranteed residual value of the asset subject to a finance lease is included in the calculation of expected credit losses under IFRS 9. The unguaranteed residual value is part of the gross investment in the finance lease, together with the minimum lease payments receivable by the lessor. Changes to unguaranteed residual value arise from fluctuations in the price that could be received for the leased asset at the end of the lease term. Paragraph 2.1(b) of IFRS 9 scopes out rights and obligations under leases to which IFRS 16 applies, except for the impairment of finance lease receivables (i.e., net investments in finance leases) and operating lease receivables recognised by a lessor (see section 2 above). IFRS 16 provides guidance on measurement of the unguaranteed residual value, which means that such measurement is within the scope of IFRS 16 rather than the impairment requirements of IFRS 9. [IFRS 16.77].

How we see it

The URV of the asset underlying a finance lease is excluded from the calculation of expected credit losses under IFRS 9. This means that the collateral that is taken into account in measuring expected credit losses excludes any amounts attributed to unguaranteed residual value and recorded on the lessor's statement of financial position. In other words, any collateral taken into account in the calculation of expected credit losses is restricted to the fair value of the right of use of the asset and not that of the underlying asset itself.

A lessor is only required to apply the impairment requirements in IFRS 9 to an operating lease receivable from the date on which it recognises the receivable. Accrued operating lease income does not represent an operating lease receivable, i.e., an amount due and payable by the lessee to the lessor and therefore is not subject to the impairment requirements of IFRS 9.2.1.(b) (i).

Frequently asked questions

Question 10-1: How does the lessor account for forgiveness of lease payments before and after the rent concession is granted under IFRS 9 and IFRS 16?

(IFRS Interpretations Committee meeting 15 March 2022 and 13 September 2022 - Agenda paper no. 4)

At its meeting in March and September 2022, the IFRS IC discussed the lessor's application of IFRS 9 and IFRS 16 in accounting for a particular rent concession in which the only change to the lease contract is the lessor's forgiveness of lease payments due from the lessee under that contract (some of which are amounts contractually due but not paid which the lessor had recognised as an operating lease receivable and some of which are amounts that are not yet contractually due). No other changes are made to the lease contract, nor are there any other negotiations between the lessor and the lessee that might affect the accounting for the rent concession. Two questions were addressed:

- (a) How the lessor applies the expected credit loss model in IFRS 9 to the operating lease receivable before the rent concession is granted if it expects to forgive payments due from lessee under the lease contract.
- (b) Whether the lessor applies the derecognition requirements in IFRS 9 or the lease modification requirements in IFRS 16 in accounting for the rent concession.

At its September 2022 meeting, the IFRS IC concluded its discussions on the tentative agenda decision published in the March 2022 IFRS IC Update. The IASB at its October 2022 meeting did not object to this agenda decision, reflecting that the IASB agreed with the agenda decision.³⁸

With respect to the first question discussed, the IFRS IC noted that as per paragraph 2.1(b)(i) of IFRS 9, operating lease receivables recognised by a lessor are subject to the derecognition and impairment requirements in IFRS 9. Consequently, the lessor is required to apply the impairment requirements in IFRS 9 to the gross carrying amount of an operating lease receivable from the date on which it recognises that receivable, taking into account applicable derecognition requirements in IFRS 9. The lessor estimates expected credit losses on the operating lease receivable by measuring any credit loss to reflect 'all cash shortfalls', which are the difference between all contractual cash flows due to the lessor in accordance with the lease contract and all the cash flows it expects to receive, determined using 'reasonable and supportable information' about 'past events, current conditions and forecasts of future economic conditions'.

The IFRS IC concluded that, before the rent concession is granted, the lessor measures expected credit losses on 'the operating lease receivable in a way that reflects 'an unbiased and probability-weighted amount ...', 'the time value of money', and 'reasonable and supportable information ...' as required by paragraph 5.5.17 of IFRS 9. This measurement of expected credit losses includes the lessor considering its expectations of forgiving lease payments recognised as part of that receivable.

With respect to the second question discussed, the IFRS IC concluded that:

- The lessor applies the derecognition requirements in IFRS 9 to forgiven lease payments that the lessor has recognised as an operating lease receivable.
As per paragraph 2.1(b)(i) of IFRS 9, operating lease receivables recognised by a lessor are subject to the derecognition requirements in IFRS 9. On granting the rent concession, the lessor legally releases the lessee from its obligation to make specifically identified lease payments, some of which the lessor had recognised as an operating lease receivable and thus has given up its contractual rights to those specifically identified cash flows. Accordingly, the lessor concludes that the requirements in paragraph 3.2.3(a) of IFRS 9 have been met as its contractual rights to the cash flows from the operating lease receivable has expired. Therefore, on the date the rent concession is granted, the lessor remeasures expected credit losses on the operating lease receivable (and recognises any change to the expected credit loss allowance in profit or loss) and derecognises the operating lease receivable and associated expected credit loss allowance.
- The lessor applies the lease modification requirements in IFRS 16 to forgiven lease payments that the lessor has not recognised as an operating lease receivable (see Chapter 24).

³⁸ [IFRIC Update September 2022](#). Available on the IFRS Foundation's website.

Other issues that have arisen in practice in relation to the IFRS 16 and IFRS 9 impairment requirements are covered further in Chapter 24. These include:

- Whether the finance income arising from a finance lease receivable is calculated based on the gross lease receivable or the net amount of the lease receivable less any expected credit losses (see Chapter 24).
- Whether (and when) lease income is recognised when collectability is not probable. Regardless of the approach followed, IFRS 9 guidance on expected credit losses continues to be applicable to recognised lease receivables (see Chapter 24).

11 Loan commitments and financial guarantee contracts

11.1 Definitions and scope

Loan commitments (see Chapter 41) are described in IFRS 9 as “firm commitments to provide credit under pre-specified terms and conditions”, while a financial guarantee contract (see Chapter 41) is defined as “a contract that requires the issuer to make specified payments to reimburse the holder for a loss it incurs because a specified debtor fails to make payment when due in accordance with the original or modified terms of a debt instrument”. [IFRS 9.BC22.2, IFRS 9 Appendix A].

If a lender is committed to provide a loan but has the ability to reprice the loan at the time of the draw-down, this will still meet the definition of a loan commitment that is subject to the IFRS 9 impairment requirements, as the lender is exposed to credit risk despite the repricing clause. However, the ability to reprice the loan may impact the exposure at default when measuring expected credit losses (see section 12.3 below).

The IFRS 9 impairment requirements apply to loan commitments and financial guarantee contracts that are not measured at fair value through profit or loss under IFRS 9, with some exceptions (see section 2 above).

Frequently asked questions

Question 11-1: Whether the impairment requirements in IFRS 9 must also be applied to other commitments to extend credit?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 22 April 2015 - Agenda paper no. 3)

The IFRS Transition Resource Group for Impairment of Financial Instruments (see section 1.4 above) discussed in April 2015 whether the impairment requirements in IFRS 9 must also be applied to other commitments to extend credit such as:

- A commitment (on inception of a finance lease) to commence a finance lease at a date in the future (i.e., a commitment to transfer the right to use an asset at the lease commencement date in return for a payment or series of payments in the future).
- A commitment by a retailer through the issue of a store account to provide a customer with credit when the customer buys goods or services from the retailer in the future.

The IFRS Transition Resource Group for Impairment of Financial Instruments appeared to agree with the IASB's staff analysis that the impairment requirements of IFRS 9 apply to an agreement that contains a commitment to extend credit by virtue of IFRS 9.2.1(g) if:

- The agreement meets the description of a loan commitment. [IFRS 9.BC22.2].
- The agreement meets the definition of a financial instrument. [IAS 32.11].
- None of the specific exemptions from the requirements of IFRS 9 apply. [IFRS 9.2.1].

The IASB staff paper stated that some contracts, such as irrevocable finance lease agreements, might clearly contain a firm commitment at inception to provide credit under pre-specified terms and conditions. However, other cases might not be so clear cut, depending upon the specific terms of the agreement and other facts and circumstances (e.g., if the issuer of a store account has the discretion to refuse to sell products or services to a customer with a store card and hence can avoid extending credit).

In the examples discussed above, the finance lease and store account do not meet the definition of a financial instrument until the contractual right to receive cash is established, that is likely to be at the commencement of the lease term or when goods or services are sold. [IAS 32.11, IAS 32.AG20]. Only lease receivables are scoped into the IFRS 9 impairment requirements (see section 10.2 above). [IFRS 9.2.1(b)]. Consequently, there is no need to make provision for expected credit losses, in accordance with IFRS 9, until a financial lease receivable or a financial asset within the scope of IFRS 9 is recognised.

11.2 The calculation of expected credit losses

The application of the model to financial guarantees and loan commitments warrants some further specification regarding some of the key elements, such as the determination of the credit quality on initial recognition, cash shortfalls and the effective interest rate to be used in the expected credit loss calculations. These specifications are summarised in Figure 11-1 below, which also highlights the differences in recognising and measuring expected credit losses for financial assets measured at amortised cost or at fair value through other comprehensive income, loan commitments and financial guarantee contracts.

Figure 11-1: Summary of the application of the expected credit loss model to loan commitments and financial guarantee contracts

	Financial assets measured at amortised cost or at fair value through other comprehensive income	Loan commitments	Financial guarantee contracts
Date of initial recognition in applying the impairment requirements (see section 7.3.1 above)	Trade date. <i>[IFRS 9.5.7.4].</i>	Date that an entity becomes a party to the irrevocable commitment. <i>[IFRS 9.5.5.6].</i>	Date that an entity becomes a party to the irrevocable commitment. <i>[IFRS 9.5.5.6].</i>
Period over which to estimate expected credit losses (see section 5.5 above)	The expected life up to the maximum contractual period (including extension options at the discretion of the borrower) over which the entity is exposed to credit risk and not a longer period. <i>[IFRS 9.5.5.19].</i>	The expected life up to the maximum contractual period over which an entity has a present contractual obligation to extend credit. <i>[IFRS 9.B5.5.38].</i> However, for revolving credit facilities (see section 12 below), this period extends beyond the contractual period over which the entity is exposed to credit risk and includes the period for which the expected credit losses would not be mitigated by credit risk management actions. <i>[IFRS 9.5.5.20, IFRS 9.B5.5.39, IFRS 9.B5.5.40].</i>	The expected life up to the maximum contractual period over which an entity has a present contractual obligation to extend credit. <i>[IFRS 9.B5.5.38].</i>
Cash shortfalls in measuring expected credit losses (see section 5.2 above)	Cash shortfalls between the cash flows that are due to an entity in accordance with the contract and the cash flows that the entity expects to receive. <i>[IFRS 9.B5.5.28].</i>	Cash shortfalls between the contractual cash flows that are due to the entity if the holder of the loan commitment draws down the loan and the cash flows that the entity expects to receive if the loan is drawn down. <i>[IFRS 9.B5.5.30].</i>	Cash shortfalls are the expected payments to reimburse the holder for a credit loss that it incurs less any amounts that the entity (issuer) expects to receive from the holder, the debtor or any other party. <i>[IFRS 9.B5.5.32].</i>
Effective interest rate used in discounting expected credit losses (see section 5.7 above)	The effective interest rate is determined or approximated at initial recognition of the financial instrument. <i>[IFRS 9.B5.5.44].</i>	The effective interest rate of the resulting asset will be applied and if this is not determinable, then the current rate representing the risk of the cash flows is used. <i>[IFRS 9.B5.5.47, IFRS 9.B5.5.48].</i>	The current rate representing the risk of the cash flows is used. <i>[IFRS 9.B5.5.48].</i>
Assessment of significant increases in credit risk (see section 6 above)	An entity considers changes in the risk of a default occurring on the financial asset. <i>[IFRS 9.5.5.9].</i>	An entity considers changes in the risk of a default occurring on the loan to which a loan commitment relates. <i>[IFRS 9.B5.5.8].</i>	An entity considers the changes in the risk that the specified debtor will default on the contract. <i>[IFRS 9.B5.5.8].</i>

Further discussion on the discount rate to be used for calculating expected credit losses on loan commitments and financial guarantee contracts is provided in section 5.7 above.

11.3 Financial guarantee contracts that require the holder to pay further premiums in the future

Frequently asked questions

Question 11-2: Whether the measurement of expected credit losses for financial guarantee contracts issued should consider future premium receipts due from the holder and, if so, how?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 22 April 2015 - Agenda paper no. 6)

At its meeting in April 2015, the IFRS Transition Resource Group for Impairment of Financial Instruments (see section 1.4 above) discussed the measurement of expected credit losses for an issued financial guarantee contract that requires the holder to pay further premiums in the future. Some members of the ITG agreed with the staff's analysis that the issuer of a financial guarantee contract should exclude future premium receipts due from the holder when measuring expected credit losses in respect of the expected cash outflows payable under the guarantee. When estimating the cash shortfalls, the amounts that the entity expects to receive from the holder should relate only to recoveries or reimbursements of claims for losses and would not include receipts of premiums. [IFRS 9.B5.5.32]. Moreover, the expected cash outflows under the guarantee depend upon the risk of default of the guaranteed asset, while the expected future premiums receipts are subject to the risk of default by the holder of the guarantee. Hence, these risks of default should be considered separately. In other words, the expected credit loss measurement should be carried out gross of any premiums receivable in the future.

In addition, an IFRS Transition Resource Group for Impairment of Financial Instruments member noted that the terms of a financial guarantee contract may affect the period of exposure to credit risk on the guarantee, for example if the guarantee were contingent or cancellable. This should be taken into consideration when measuring the expected credit losses of the guarantee.

IFRS 9 requires that financial guarantees and off-market loan commitments are measured at the 'higher of' the amount initially recognised less cumulative amortisation, and the expected credit loss. [IFRS 9.4.2.1(c), IFRS 9.4.2.1(d)]. For a financial guarantee contract issued to an unrelated party in a stand-alone arm's length transaction, premiums that are received in full at inception will likely be the same as the fair value of the guarantee at initial recognition (see Chapter 45). In such circumstances, it is likely that no expected credit losses will need to be recognised immediately after initial recognition, as the initial fair value will normally exceed the lifetime expected credit losses. However, a financial guarantee contract for which premiums are receivable over the life of the guarantee will have a nil fair value at initial recognition. In such circumstances, the subsequent measurement of the financial guarantee contract is likely to be based on the expected credit loss allowance. This is shown in the Illustration below.

Illustration 11-1: Determining the initial and subsequent measurement of a financial guarantee contract where premiums are receivable upfront or over the life of the guarantee

- | | |
|-------------|--|
| Scenario 1: | On 1 January 20X2, Bank A issues a 5 year financial guarantee of a loan with a nominal value of CU2,000,000 with 5% interest, with the full premium of CU100,000 receivable upfront at contract inception. This premium is recognised on a straight-line basis over the life of the guarantee. As at 31 December 20X4 and 20X5, Bank A assesses that there has been a significant increase in credit risk of the financial guarantee contract and as at 31 December 20X6, the debtor defaults and fails to make payments in accordance with the terms of the debt instrument. The lifetime expected credit losses estimated as at 31 December 20X2 and 20X3 are CU75,000 and CU55,000 respectively, with a significant increase in 20X4 and 20X5 to CU200,000 and CU500,000, respectively, and for the guaranteed amount of CU2,100,000 (being the principal and unpaid interest) in 20X6 when the debtor defaults. The 12-month expected credit losses are CU18,000 and CU25,000 as at 31 December 20X2 and 20X3. |
| Scenario 2: | Same facts as in Scenario 1 except that Bank B issues a 5 year financial guarantee of a loan with a nominal value of CU2,000,000, with premiums receivable over the life of the guarantee of CU20,000 each year, payable on 31 December 20X2, 20X3, 20X4, 20X5 and 20X6, i.e., a total of CU100,000. The fair value of the guarantee is nil at origination. If a claim is paid out under the financial guarantee contract, Bank B will lose the right to receive future premiums. |

	31 Dec 20X2 CU	31 Dec 20X3 CU	31 Dec 20X4 CU	31 Dec 20X5 CU	31 Dec 20X6 CU
Scenario 1: Full premium of CU100,000 receivable at inception					
Initial fair value is CU100,000					
(a) Fair value less cumulative income recognised*	80,000	60,000	40,000	20,000	-
(b) Expected credit losses	18,000	25,000	200,000	500,000	2,100,000
Recorded value: higher of (a) or (b) in accordance with IFRS 9.4.2.1(c)	80,000	60,000	200,000	500,000	2,100,000
Scenario 2: Premium receivable over the life of contract, i.e., CU20,000 per annum					
Initial fair value is CU0 in accordance with IFRS 9.5.1.1					
(a) Fair value less cumulative income recognised*	-	-	-	-	-
(b) Expected credit losses	18,000	25,000	200,000	500,000	2,100,000
Recorded value: higher of (a) or (b) in accordance with IFRS 9.4.2.1(c)	18,000	25,000	200,000	500,000	2,100,000

* Based on the assumption of a straight-line amortisation of premiums received over the life of the financial guarantee.

Before there has been a significant increase in credit risk in 20X2 and 20X3, in Scenario 1, the measurement of the financial guarantee is based on the fair value, less cumulative income recognised in accordance with IFRS 15 whilst, in Scenario 2, the measurement is based on the expected credit loss allowance. However, once there has been a significant increase in credit risk, the measurement of the financial guarantee is based on the expected credit loss allowance in both scenarios. Consequently, the timing of receipt of premiums may have a significant effect on the measurement of the guarantee particularly when there has not been a significant increase in credit risk.

Although the accounting treatment in Scenario 2 in the example above may seem unintuitive, in that the guarantor must initially recognise expected credit losses even though it expects to receive future premium income, it is consistent with the impairment of loans on which a credit spread is also received over the life of the loan.

Normal loan commitments (i.e., those issued at market interest rates and therefore excluded from the scope of IFRS 9 except for impairment and derecognition) [IFRS 9.2.1(g), IFRS 9.2.3] are not subject to the 'higher of' test for subsequent measurement. [IFRS 9.2.3(c), IFRS 9.4.2.1(d)]. The consequence is that an expected credit loss is required for all normal loan commitments, whether or not any fees are paid upfront. This is consistent with the general requirement to provide for 12-month expected credit losses for any new loans that have not experienced significant increases in credit risk since initial recognition.

11.4 Cross-company guarantees

For the individual entities within a group, there may be instances where cross-company guarantee arrangements will meet the definition of financial guarantee contracts and hence will fall within the scope of the IFRS 9 expected credit loss requirements. [IFRS 9.4.2.1(d)].

Where such guarantees are provided at below-market rates by holding companies or other group entities, the initial benefit provided may need to be accounted for as an equity transaction between group entities.

When estimating the expected credit losses on cross-company guarantees relating to loans to a group entity made by parties external to the group, each entity that is a party to the cross-company guarantee arrangement needs, for its standalone financial statements, to factor in the likelihood of it being called upon to make payments under the arrangement. A practical approach would be to determine the total expected credit losses and then allocate them to group entities, based on an assessment of which entities will most likely settle the guarantee if payment is required. In doing so, all reasonable and supportable information that is available, including the respective entities' relative financial strength in relation to other group entities will need to be taken into account. If one entity in the group is expected to reimburse the lender, then this will reduce the potential cash shortfall estimated by other entities within the group. For example, if the parent is in the strongest financial position and is expected to fully reimburse the lender for a loan issued to one of its subsidiaries, then the parent's estimate of cash shortfalls would be consistent with the cash shortfalls that the lender could suffer in the absence of the guarantee. However, once the expected payments from the parent are taken into account, this would significantly reduce the expected cash shortfalls estimated by other group entities. This will result in each entity recognising the appropriate probability-weighted estimate of credit losses. Requiring all entities to recognise an expected credit loss amount which does not take into account the likelihood of being called upon would not represent a probability-weighted estimate of credit losses and would not provide useful information to users of the financial statements.

Additional disclosures would be required to explain the arrangement, including the maximum amount to which the entity is exposed and how the expected credit loss amount has been calculated. [IFRS 7.36(a), IFRS 7.35G]. Also, IAS 24 *Related Party Disclosures* requires details of any guarantees given to, or received from, related parties to be disclosed. [IAS 24.18, IAS 24.21].

11.5 Purchased or originated credit-impaired loan commitments and financial guarantee contracts

Another question that arises in practice is whether loan commitments and financial guarantee contracts can ever be accounted for as purchased or originated credit-impaired. The definition of 'purchased or originated credit-impaired' in IFRS 9 refers only to financial assets, not financial instruments (consistent with the definition of credit-impaired) but loan commitments and financial guarantees are not financial assets. So, if such an instrument is entered into when default is highly likely or has already occurred, and the potential loss is reflected in the price, how are the expected credit losses measured, so as to avoid double counting the loss?

This issue could be particularly relevant in the context of business combinations, where an entity may acquire loan commitments or financial guarantee contracts that are already credit-impaired. For financial guarantees, the 'higher of' test avoids the double-counting, as the fair value of the guarantee recognised as a liability on initial recognition will be higher than lifetime expected losses. For loan commitments, one view could be to consider they are at below-market interest rates on initial recognition (as the terms were fixed at a time where the loan commitment was not credit-impaired) and apply the higher of test; alternatively, one may consider that the guidance for financial assets may be applied by analogy to loan commitments. This would make sense as IFRS 9 treats loans that are drawn from a loan commitment as a continuation of the same financial instrument. For disclosure purposes, we believe such loan commitments and financial guarantees ought to also be reported as credit-impaired.

How we see it

For accounting and disclosure purposes, we believe loan commitments and financial guarantee contracts can be treated as purchased or originated credit-impaired if default is likely or has already occurred.

12 Revolving credit facilities

The 2013 ED specified that the maximum period over which expected credit losses are to be calculated is limited to the contractual period over which the entity is exposed to credit risk.³⁹ This would mean that the allowance for commitments that can be withdrawn at short notice by a lender, such as overdrafts and credit card facilities, would be limited to the expected credit losses that would arise over the notice period, which might be only one day. However, banks will not normally exercise their right to cancel the commitment until there is already evidence of significant deterioration, which exposes them to risk over a considerably longer period. Banks and banking regulators raised concerns on this issue and the IASB responded by introducing an exception for revolving credit facilities and setting out further guidance as well as an example addressing such arrangements.

In outline, the revolving credit facility exception requires the issuer of such a facility to calculate expected credit losses based on the period over which they expect, in practice, to be exposed to credit risk. However, the words of the exception are not very clear and it was discussed at all three IFRS Transition Resource Group for Impairment of Financial Instruments meetings. The IASB staff have also produced a webcast on the topic.

12.1 Scope of the exception

The guidance relates to financial instruments that 'include both a loan and an undrawn commitment component and for which the entity's contractual ability to demand repayment and cancel the commitment does not limit the entity's exposure to credit losses to the contractual notice period'. [IFRS 9.5.5.20]. Despite the use of the word 'both', the IFRS Transition Resource Group for Impairment of Financial Instruments agreed, in April 2015, that this guidance applies even if the facility has yet to be drawn down. It also applies if the facility has been completely drawn down, as it is the nature of revolving facilities that the drawn down component is periodically paid off before further amounts will be drawn down again in future.

IFRS 9 also describes three characteristics generally associated with such instruments: [IFRS 9.B5.5.39]

- They usually have no fixed term or repayment structure and usually have a short contractual cancellation period
- The contractual ability to cancel the contract is not enforced in day-to-day management, but only when the lender is aware of an increase in credit risk at the facility level
- They are managed on a collective basis

Products that are generally agreed to be in the scope of the exception include most credit card facilities and most retail overdrafts. However, even with these some caution needs to be applied, since we understand that there are credit card facilities which do not enable the issuer to demand repayment and cancel the facility, and which would therefore be out of scope.

What is less clear is the treatment of corporate overdrafts and similar facilities. It is relevant that all the IFRS Transition Resource Group for Impairment of Financial Instruments discussions as well as the webcast referred to credit cards and retail customers and not corporate exposures. The problem is partly that the guidance to IFRS 9 describes management on a collective basis as a characteristic that revolving facilities in the scope of the exception 'generally have', rather than a required feature as listed in IFRS 9.5.5.20.

[IFRS 9.B5.5.39]. Some banks consider this is still a determining feature and that many of their corporate facilities are outside the scope of the exception because they are managed on an individual basis. Banks normally have a closer business relationship with their larger corporate customers than with most retail customers, and more data to manage the credit risk, such as access to regular management information. Other banks consider that facilities that are individually managed are still in the scope of the exception, notably because individual credit reviews are generally performed only on an annual basis (unless a significant event occurs). In addition, it is unclear exactly what is meant by 'managed on a collective basis' and where to draw the line between large corporates and smaller entities. It is noted that if a corporate facility is not deemed to be a revolving facility, but can be cancelled at short notice, the expected credit losses will be limited to those that arise over the notice period.

39 Exposure Draft [ED/2013/3](#): *Financial Instruments: Expected Credit Losses*, IASB, March 2013, para. 17. Available on the IFRS Foundation's website.

Frequently asked questions

Question 12-1: Whether multi-purpose credit facilities would fall within the scope of IFRS 9.5.5.20 and whether the general characteristics identified in IFRS 9.B5.5.39 should be considered to be required characteristics, or merely examples of typical characteristics?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 11 December 2015 - Agenda paper no. 2)

At its December 2015 meeting (see section 1.4 above), the IFRS Transition Resource Group for Impairment of Financial Instruments discussed whether:

- Multi-purpose credit facilities, which have the ability to be drawn down in a number of different ways (e.g., as a revolving overdraft, a variable or fixed-rate loan with or without a fixed term or an amortising loan such as a mortgage) would fall within the scope exception.
- The general characteristics identified in IFRS 9.B5.5.39 should be considered to be required characteristics, or merely examples of typical characteristics.
- The existence of a fixed term of the loan once drawn down would prevent a facility from falling within the scope exception.

The IFRS Transition Resource Group for Impairment of Financial Instruments commented that:

- The supporting application guidance in IFRS 9.B5.5.39 reinforces the features described in IFRS 9.5.5.20 by setting out general characteristics which, while not determinative, are consistent with those features.
- The Basis for Conclusions of IFRS 9 provides further context around the type of financial instruments that the Board envisaged would fall within the scope exception. In particular, the exception was intended to be limited in nature and that it was introduced in order to address specific concerns raised by respondents in relation to revolving credit facilities that were managed on a collective basis. Also, it was understood that these types of financial instruments included both a loan and an undrawn commitment component and that they were managed, and expected credit losses were estimated, on a facility level; i.e., the drawn and undrawn exposure were viewed as one single cash flow from the borrower. [IFRS 9.BC5.254-261].
- Consequently, both the drawn and undrawn components of these facilities were understood to have similar short contractual maturities, i.e., the lender had both the ability to withdraw the undrawn commitment component and demand repayment of the drawn component at short notice.
- An immediately revocable facility which has a fixed maturity (e.g., 5 years) would be consistent with the type of facility within the scope exception because the fixed term feature does not negate the lender's contractual right to cancel the undrawn component at any time. In contrast, an immediately revocable facility that has no fixed maturity but when drawn, can take the form of a loan with a fixed maturity (i.e., once it has been drawn, the lender no longer has the right to demand immediate repayment at its discretion) would not be consistent with the type of facility envisaged to be within the scope exception. This is because the fixed term feature does negate the lender's contractual right to demand repayment of the undrawn component. However, regarding this characteristic, the IFRS Transition Resource Group for Impairment of Financial Instruments members also highlighted the following:
 - (a) An entity would first need to establish the unit of account to which the requirements of IFRS 9 should be applied. In this regard, they noted that even if there was only one legal contract supporting a particular multi-purpose credit facility, there might be more than one unit of account to consider.
 - (b) If the fixed-term feature was for a shorter period, judgement would be required in order to determine whether such a fixed-term feature would prevent a particular financial instrument from falling within the scope exception (e.g., whether the borrower could consider the exposure on the drawn and undrawn components to be one single cash flow).
- IFRS 7 requires an entity to explain, among other things, the assumptions used to measure expected credit losses. Within the context of multi-purpose credit facilities, such disclosures are likely to be important in order to meet the disclosure objectives (see section 15 below and Chapter 50).

While, according to the IFRS Transition Resource Group for Impairment of Financial Instruments, the drawn and undrawn exposures are viewed as 'one set of cash flows from the borrower', IFRS 9's Basis for Conclusions is slightly clearer. [IFRS 9.BC5.259]. It states that the loan and undrawn commitment are managed, and expected credit losses are estimated on a facility level. In other words, there is only one set of cash flows from the borrower that relates to both components. Hence, the drawn and undrawn elements of a revolving facility within the scope of the exception would normally be viewed as only one unit of account. The IFRS Transition Resource Group for Impairment of Financial Instruments discussion seems to suggest that a new unit of account would be recognised if a borrower chose to draw down on a multi-purpose facility in the form of a term loan, because this is the point where this specific drawn portion ceases to share the key characteristic of a revolving facility, i.e., the entity's contractual ability to demand repayment and cancel the commitment.

Question 12-2: How future drawdowns should be estimated when a revolving credit facility might not have a specified credit limit in the contract?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 11 December 2015 - Agenda paper no. 3)

At its December 2015 meeting (see section 1.4 above), the IFRS Transition Resource Group for Impairment of Financial Instruments discussed charge cards and how expected credit losses on future drawdowns should be measured if there is no specified credit limit in the contract. The IFRS Transition Resource Group for Impairment of Financial Instruments members considered a specific fact pattern where the bank has the ability to approve each transaction at the time of sale based on the customer's perceived spending capacity using statistical models and inputs such as spending history and known income.

The IFRS Transition Resource Group for Impairment of Financial Instruments members noted that because the bank has the right to refuse each transaction at its discretion, and on the assumption that the bank actually exercises that right in practice, then:

- The contractual credit limit should be considered to be zero and consequently future drawdowns would not be taken into account.
- Furthermore, the facility described would not fall within the scope exception because there would be no undrawn commitment component (i.e., there is no firm commitment to extend credit).

However, the IFRS Transition Resource Group for Impairment of Financial Instruments members noted that their discussions focussed on the very specific fact pattern presented and observed that the conclusion could differ in other situations.

12.2 The period over which to measure expected credit losses

12.2.1 The requirements of IFRS 9

IFRS 9 has an exception for revolving credit facilities that requires the issuer of such a facility to calculate expected credit losses based on the period over which they expect, in practice, to be exposed to credit risk rather than limited to the contractual period over which the entity is exposed to credit risk: [IFRS 9.5.5.20, IFRS 9.B5.5.40]

Extract from IFRS 9

5.5.20 However, some financial instruments include both a loan and an undrawn commitment component and the entity's contractual ability to demand repayment and cancel the undrawn commitment does not limit the entity's exposure to credit losses to the contractual notice period. For such financial instruments, and only those financial instruments, the entity shall measure expected credit losses over the period that the entity is exposed to credit risk and expected credit losses would not be mitigated by credit risk management actions, even if that period extends beyond the maximum contractual period.

B5.5.40 When determining the period over which the entity is expected to be exposed to credit risk, but for which expected credit losses would not be mitigated by the entity's normal credit risk management actions, an entity should consider factors such as historical information and experience about:

- (a) the period over which the entity was exposed to credit risk on similar financial instruments;
- (b) the length of time for related defaults to occur on similar financial instruments following a significant increase in credit risk; and
- (c) the credit risk management actions that an entity expects to take once the credit risk on the financial instrument has increased, such as the reduction or removal of undrawn limits.

The above wording in IFRS 9 is not very easy to interpret or apply. The period over which to measure expected credit losses and the relevant exposures are estimated based on historical experience and future expectations of when facilities are expected to no longer expose the lender to risk, because the customer (i) defaults; (ii) no longer uses the facility; or (iii) the credit line is reduced or removed by the lender. Ultimately, the estimation of the maximum period to consider would require judgement and consequently the disclosure requirements of IFRS 7 (such as those explaining inputs, assumptions and estimation techniques in relation to expected credit losses) would be relevant.

12.2.2 Guidance provided by the IFRS Transition Resource Group for Impairment of Financial Instruments

When assessing the period over which to measure expected credit losses for revolving credit facilities, it is clear that the starting-point is the reporting date. However, with respect to the ending-point, IFRS 9 is less clear.

IFRS 9 requires an entity to consider historical information and experience about the period over which the entity was exposed to credit risk on similar financial instruments, the length of time for related defaults to occur on similar financial instruments following a significant increase in credit risk; and the credit risk management actions that an entity expects to take once the credit risk on the financial instrument has increased, such as the reduction or removal of undrawn limits.

Also, the IFRS Transition Resource Group for Impairment of Financial Instruments discussed this issue in the April and December 2015 IFRS Transition Resource Group for Impairment of Financial Instruments meetings and commented that an entity also needs to consider the expected defaults, asset curing, and potential credit risk management actions the entity expects to be legally and operationally able to take and that serve to either terminate or limit the credit risk exposure in some way (e.g., reduction or removal of undrawn limits).

Frequently asked questions

Question 12-3: What is the maximum period to consider when measuring expected credit losses for revolving credit facilities?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 22 April 2015 - Agenda paper no. 4)

The IFRS Transition Resource Group for Impairment of Financial Instruments in April 2015 (see section 1.4 above), discussed how to determine the appropriate period when measuring expected credit losses for a portfolio of revolving credit card exposures in stages 1, 2 and 3 and commented that:

- An entity's ability to segment and stratify the portfolio into different sections of exposures in accordance with how those exposures are being managed will be relevant. For example, an entity may be able to identify exposures with specific attributes that are considered more likely to default and consequently would have shorter average lives than those that are expected to continue performing (see section 6.5 above).
- While IFRS 9 requires a period in excess of the maximum contractual period to be used when measuring expected credit losses, the fundamental aim was still to determine the period over which the entity is exposed to credit risk and an entity must consider all three factors set out in IFRS 9.B5.5.40. Consequently, expected defaults or potential credit risk management actions the entity expects to be legally and operationally able to take and that serve to terminate or limit the credit risk exposure in some way (e.g., reduction or removal of undrawn limits) could result in a shorter period of exposure than that indicated by the historical behavioural life of the facility. That is, the time horizon is not the period over which the lender expects the facility to be used, but the period over which the lender is, in practice, exposed to credit risk.

Question 12-4: When does the period start and end in assessing the maximum period when measuring expected credit losses for revolving credit facilities?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 11 December 2015 - Agenda paper no. 4)

At its December 2015 meeting (see section 1.4 above), the IFRS Transition Resource Group for Impairment of Financial Instruments continued the discussion on how an entity should determine the maximum period to consider when measuring expected credit losses for revolving credit facilities in accordance with IFRS 9.B5.5.40. This divided into two sub-questions:

- (a) How should an entity determine the starting-point of the maximum period to consider when measuring expected credit losses?
- (b) How should an entity determine the ending-point of the maximum period to consider when measuring expected credit losses, in particular, which credit risk management actions should an entity take into account in making this determination?

With respect to the starting-point, the IFRS Transition Resource Group for Impairment of Financial Instruments members observed that the requirements of IFRS 9.B5.5.40 do not alter the starting-point of the maximum period to consider when measuring expected credit losses and consequently, the appropriate starting-point should be the reporting date.

With respect to the ending-point, IFRS Transition Resource Group for Impairment of Financial Instruments members focused on which credit risk management actions an entity should take into account and noted that:

- An entity should consider:
 - (a) Only credit risk management actions that it expects to take rather than all credit risk management actions that it is legally and operationally able to take.
 - (b) Only those credit risk management actions that serve to mitigate credit risk and consequently, actions that do not mitigate credit risk such as the reinstatement of previously curtailed credit limits should not be considered.
 - (c) All credit risk management actions that it expects to take and that serve to either terminate or limit the credit risk exposure in some way.
- An entity's expected actions must be based on reasonable and supportable information. In this regard, consideration should be given to an entity's normal credit risk mitigation process, past practice and future intentions.

- The ending-point could be limited by the expected timing of the entity's next review process, but only if the entity's normal business practice is to take credit risk mitigation actions as part of this review process. Consequently, it may not always be appropriate to use the timing of the entity's next review process as a basis for determining the ending-point.
- In respect of assets in stage 2, the probability of assets curing or defaulting would need to be taken into account when determining the maximum period to consider when measuring expected credit losses.
- It was noted that a distinction should be made between credit risk management actions such as the reinstatement of a previously curtailed credit limit (that should not be taken into account) and considering how a particular stage 2 exposure that has not yet been subject to any credit risk mitigation actions will develop. For example, an entity may have determined that there has been a significant increase in credit risk since initial recognition in respect of a particular exposure but may not yet have taken any specific credit risk mitigation actions such as the curtailment or termination of the credit limit. In this case, consideration should be given to the possibility that the exposure may cure rather than default. In contrast, if an entity had taken credit risk mitigation action in respect of that exposure such as the curtailment of the credit limit, it would not be appropriate to take into consideration the possibility that the exposure may subsequently cure, resulting in a reinstatement of the previously curtailed credit limit when determining the maximum exposure period. In this regard, appropriate portfolio segmentation is crucial, in particular in relation to financial assets in stage 2.
- There is only one maximum exposure period to consider, which applies equally to both the drawn and undrawn components of a revolving credit facility, which is consistent with the way in which the facility is managed. Nevertheless, in measuring expected credit losses, credit risk mitigation actions may affect the drawn and undrawn components differently. For example, when an entity cancels the undrawn component, the possibility of any future drawdowns is removed, whereas when an entity demands repayment of the drawn component the recovery period associated with that drawn exposure still needs to be considered in measuring expected credit losses.
- Ultimately, the estimation of the maximum period to consider would require judgement and consequently the disclosure requirements of IFRS 7 (such as those explaining inputs, assumptions and estimation techniques in relation to expected credit losses) would be important (see section 15 below and Chapter 50).

12.2.3 Guidance provided by the IASB webcast

On 16 May 2017 the IASB issued a webcast titled *IFRS 9 Impairment: The expected life of revolving facilities*. Like other IASB webcasts, this sets out the views of the speakers rather than the Board, but it is nevertheless regarded as important educational material. The webcast indicated that the expected life will be bound by expected defaults, or when the facility is no longer used by the customer, or the next review date to the extent that credit risk mitigation actions are expected to occur.

This webcast used the example of a portfolio of 100 similar facilities, 30 of which are expected to significantly increase in credit risk by the next credit review and, at the next credit review, based on past experience, 5 of these facilities will be cut. The key messages provided were:

- The entity assumes that the expected life of the portfolio will be limited by the period to the next credit review only for those 5 facilities. This is because the expected life can only be reduced to the next review date to the extent that mitigation actions are expected to occur.
- It is not necessary to know in advance which 5 facilities will be cut.
- The expected life of the other 95 facilities will be bounded by when they are expected to default or the point at which the facility is no longer used by the customer.
- Meanwhile, the expected life for the 5 facilities may be shorter than the time to the next review if they are expected to default.
- As discussed at the IFRS Transition Resource Group for Impairment of Financial Instruments, it will be necessary to segment the portfolio appropriately into groups of loans with similar credit and payment expectations in order to determine its expected life. If a facility is more likely to default, then it is also more likely to be subject to risk mitigation action.
- If the entity expects, based on past experience, to cut the facility only in part, by reducing the limit, then the life of the facility will be cut only for the portion of the facility that is expected to be withdrawn.

This example only looks forward to what it expects to happen by the time of the next credit review. Presumably it would be appropriate to extend the analysis to look beyond this to subsequent reviews and further reductions in facilities expected in the future to help determine the expected life of the remaining 95 facilities in the portfolio. This is illustrated by Illustration 12-1 below.

A second example in the webcast compared two entities: Entity A only cancels undrawn facilities that deteriorate to a risk classification of 20, while Entity B cancels any facility as soon as it deteriorates to a classification of 15 (and so lower risk than grade 20). It was concluded that, all else being equal, the expected life for entity A's portfolio will be longer than for entity B's portfolio.

As discussed at the IFRS Transition Resource Group for Impairment of Financial Instruments meetings, the IASB staff noted that it will be necessary to segment the portfolio appropriately into groups of loans with similar credit and payment expectations in order to determine its expected life.

It needs to be stressed that estimating the expected life of a revolving facility is of relevance mostly for those facilities that are measured using lifetime expected credit losses. The allowance for those assets in stage 1 will be calculated based only on losses associated with default in the next twelve months, which is likely to be the period used to measure expected credit losses unless the entity's risk mitigation activities indicate that a shorter period is to be used.

To recap, it would seem that a periodic credit review is normally taken into account when assessing the period over which to measure losses to the extent that it is expected to result in reduction or withdrawal of actual limits. Hence, for example, if normally 20% of facilities are withdrawn based on an annual review, then for 20% of the outstanding facilities the period to measure losses is limited by the timing of this next review. For the other 80% of the facilities, three things may happen: they may someday default, the facility may someday be reduced or withdrawn, or the borrower may someday cease to use the card. For the 80% it is necessary to model each of these possibilities, which means that the period over which to measure expected credit losses may extend for a number of years into the future. Under this view IFRS 9's requirement for any facilities measured using lifetime expected credit losses can be simply summarised as 'how much do you expect to lose'?

How we see it

In addition to forecasting the possibilities of the borrower defaulting or ceasing to use the revolving facility, a periodic credit review is normally taken into account when assessing the period over which to measure losses to the extent that it is expected to result in limit reduction or withdrawal.

The application of this approach is shown in the following Illustration.

Illustration 12-1: Estimating the life of revolving credit facilities

Of 1,000 facilities in stage 2 the entity estimates that each year:

- 10% will default every year in the first three years, but this reduces to 2% thereafter, as those facilities that do not default in the first three years are expected to have become significantly lower risk.
- 8% of holders will cease to use their card every year in the first three years but this increases to 15% thereafter once their financial position has improved.
- 15% of facilities will be withdrawn each year, as credit risk mitigation, over the first three years. After that period it is assumed that the credit risk is significantly reduced and none of the facilities are reduced thereafter.

No. of facilities in stage 2	Year 1	Year 2	Year 3	Year 4	Year 5	Year 6	Year 7
Balance brought forward	1,000	670	448	301	250	207	172
Defaults	(100)	(67)	(45)	(6)	(5)	(4)	(3)
Cease to use card	(80)	(54)	(35)	(45)	(38)	(31)	(26)
Facility withdrawn	(150)	(101)	(67)	-	-	-	-
Balance carried forward	670	448	301	250	207	172	143

In this example it is apparent that while the level of defaults quickly declines, a small portion of the portfolio has a very long life. The consequence is that the expected credit loss could be very significant. However, the example does not take account of the time value of money. Given the high interest rate charged on credit cards, the manner in which interest is included in the estimation of cash flows and how losses are discounted will have a major impact upon the expected credit loss measurement (see section 12.4 below). One method that we have observed being applied to make this calculation is to track a portfolio of stage 2 facilities over a number of years and note how long it takes for the default rate to reduce to an immaterial level.

12.2.4 Interaction with derecognition

A further issue is the extent to which the period over which to measure expected credit losses is restricted by the normal derecognition principles of IFRS 9 and what could constitute a derecognition of the facility. In particular, it is unclear whether the existence of a contractual life and/or the lender's ability to revise the terms and conditions of the facility based on periodic credit reviews as thorough as that on origination, would be regarded as triggers for derecognition and so would also limit the life for expected credit loss measurement.

Frequently asked questions

Question 12-5: How to determine the date of initial recognition of a revolving credit facility for the purposes of the assessment of significant increases in credit risk?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 22 April 2015 - Agenda paper no. 4)

In April 2015, the IFRS Transition Resource Group for Impairment of Financial Instruments (see section 1.4 above) discussed how to determine the date of initial recognition of a revolving credit facility for the purposes of the assessment of significant increases in credit risk. The challenge presented was how to determine when changes are sufficiently significant to result in a derecognition of the original facility and recognition of a new facility. The IFRS Transition Resource Group for Impairment of Financial Instruments members discussed some of the factors that might be taken into consideration in making that judgement, such as issuing a new card, revising credit limits or conducting credit reviews.

It was noted that judgement would be required in making this assessment and that it would depend on the specific facts and circumstances. However, the following observations were made:

- (a) In some circumstances issuing a new card may be indicative that the original facility has been derecognised, but in other cases, this may be a purely operational process and thus would not indicate that a new facility has been issued.
- (b) Credit reviews in themselves may not indicate that a new facility has been issued.

Although this discussion was on how to determine the reference date for assessing if there has been a significant increase in credit risk, the notion that it depends on the derecognition of one facility and the recognition of a new one would, presumably, be equally relevant for assessing the period over which to measure expected credit losses. This is especially relevant for corporate overdraft facilities which are considered to be in the scope of the exception (see section 12.1 above). If, for instance:

- (a) The facility has a clearly agreed contractual life of one year (in addition to a short cancellation notice period)
 - (b) The bank goes through a thorough credit process each year, similar to that on original application and using detailed financial and other information specific to the customer, before deciding whether to continue with the facility, increase it, reduce it or withdraw it
 - (c) The bank will at that time revise the terms and conditions of the facility to reflect the up-to-date credit quality of the borrower
 - (d) The bank derecognises the facility and recognises a new one, giving the associated required disclosures
- Intuitively, it would seem that the bank is only exposed to credit risk for the period of a year.

This is consistent with the Basis for Conclusions which confirms the general principle that, “if an entity decides to renew or extend its commitment to extend credit, it will be a new instrument for which the entity has the opportunity to revise the terms and conditions.” [IFRS 9.BC5.260]. Also, while IFRS 9.BC5.261, by starting with the word ‘however’, makes it clear that the revolving facilities amendment was an exception to this principle, it does not explicitly state that it is an exception to the entire principle. It only says that “the entity’s contractual ability to demand repayment and cancel the undrawn commitment does not limit the entity’s exposure” remaining silent on an entity’s ability to renew or extend credit. On the other hand, some believe that an ability to withdraw or cancel is in substance sufficiently similar to an ability to renew or extend, that they are treated the same. They also consider that the IASB webcast has made it clear that only expected reductions and withdrawals of facilities can be reflected in the assessment of the risk horizon. Consequently, a decision to maintain the facility, even if based on fully revised terms and conditions, would not be considered a risk management decision that shortens the life of the facility.

There are also differences of view as to whether a revolving facility can be derecognised (and so the expected derecognition can be reflected in the expected credit loss horizon) if the lender carries out an annual thorough periodic credit review at least equivalent to that when the facility was first granted, at which point it may revise the terms and conditions, but there is no contractual limit to the life of the facility, or if there is a contractual limit to the life of the facility but no thorough credit review at the point of renewal. In the first case, the contract allows for a periodic credit review equivalent to that on origination, performed on an individual rather than a collective basis and with an opportunity to revise the terms and conditions if the credit quality has changed, some believe that this could lead to derecognition of the facility and recognition of a new one. As a result, expected credit losses would only be measured over the period until the next periodic review. In the second case, the facility has a clearly agreed contractual life but its renewal is relatively automatic without a thorough review. Some believe that IFRS 9 is clear that a financial instrument is derecognised if it expires and therefore a thorough credit review is not required.

It is important for banks to disclose the basis on which they have made their calculations.

It needs to be stressed that this issue is of relevance mostly for those facilities that are measured using lifetime credit losses. The allowance for those assets in stage 1 will be calculated based only on losses associated with default in the next twelve months.

12.3 Exposure at default

To measure expected credit losses on revolving facilities, such as credit cards, it will be necessary to estimate several components that make up the exposure at default:

- The credit conversion factor, to determine the portion of the undrawn revolving credit facility at the reporting date that will be drawn down at the time of default in any period (limited for facilities in stage 1 to the next twelve months)
- The speed at which drawn down facilities are paid off
- The level of interest expected to be charged in the future on those facilities that are drawn down

These components will all need to be estimated based on past experience and future expectations, for sections of the portfolio that are segmented so that they have similar credit characteristics (see section 6.5.2 above). The estimation of interest is addressed further in section 12.4 below.

How we see it

In practice, for many credit cards, the exposure in the event of default reaches close to the credit limit and may even exceed it. However, IFRS 9 does not permit the use of a credit conversion factor of more than 100%. For this reason, the use of a conventional credit conversion factor model for estimating the exposure at default may need to be adjusted to comply with IFRS 9.

Frequently asked questions

Question 12-6: Whether an exposure in excess of the contractually agreed credit limit could be used when estimating the exposure at default for revolving credit facilities in accordance with IFRS 9 when an entity has a history of allowing customers to exceed their contractually set credit limits?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 16 September 2015 - Agenda paper no. 3)

At its meeting on 16 September 2015, the IFRS Transition Resource Group for Impairment of Financial Instruments (see section 1.4 above) discussed how an entity estimates future drawdowns on undrawn lines of credit and noted that:

- The exception for some types of revolving credit facilities set out in IFRS 9.5.5.20 relates to the contractual commitment period and does not address the contractual credit limit. IFRS 9 was clear in this regard and consequently, it would not be appropriate to analogise this specific exception to the contractual credit limit.
- Some members of the IFRS Transition Resource Group for Impairment of Financial Instruments pointed out that, in practice, the tenor and amount of revolving credit facilities are inextricably linked, because banks not only extend credit for a period in excess of their maximum contractual commitment period but also allow customers to make drawdowns in excess of the maximum contractually agreed credit limit as notified to the customer. Consequently, if amounts in excess of the maximum contractually agreed credit limits are not taken into account, there would be a potential disconnect between the accounting and credit risk management view.
- However, it was concluded that IFRS 9 limits the estimation of future drawdowns to the contractually agreed credit limit.

12.4 Time value of money

The time value of money is important in measuring expected credit losses for revolving facilities since interest rates (when interest is charged) are high. Hence it is important that any interest that is expected to be charged on drawn balances is included in the exposure at default and that an appropriate rate is used to discount expected credit losses. An additional complexity is introduced by credit cards, because they typically have a grace period in which no interest is charged as long as the amount drawn down is repaid within a specified period of time.

According to the guidance for 'normal' loan commitments, the expected credit losses on a loan commitment must be discounted using the effective interest rate, or an approximation thereof, that will be applied when recognising the financial asset resulting from the loan commitment. [IFRS 9.B5.5.47]. Applying this approach, the expected credit losses on the currently undrawn portion of a revolving facility is discounted based on the rate that is likely to be charged if it is drawn down. However, the IFRS Transition Resource Group for Impairment of Financial Instruments discussion on the scope of revolving credit facilities in December 2015 (see section 12.1 above) noted that the drawn and undrawn balances are viewed as one unit of account and so discounted at the same rate. This could be nil for a credit card customer that is a 'transactor', that is, one who repays any amount drawn down within the specified short period and so is charged no interest. If it is expected that interest will be charged at the high rate, which is likely for most facilities that are already 'revolvers', that is, those facilities where the borrower only pays off the minimum amounts permitted by the issuer (in effect, using the card to borrow money), then the discount rate is likely to be the high rate. If it is projected that a transactor, will at some stage become a revolver before it defaults, then it may be appropriate to calculate a blended discount rate.

In addition, at the same meeting, the IFRS Transition Resource Group for Impairment of Financial Instruments discussion on the use of floating-rates of interest to measure expected credit losses (see section 5.7 above) established a useful principle, that there should be consistency between the rate used to recognise interest revenue, the rate used to project future cash flows (including shortfalls) and the rate used to discount those cash flows.

Because the choice of interest rate used to project cash flows and to discount losses will depend on expectations of the borrower's behaviour, it will need to be made separately for segments of the portfolio with similar credit and payment characteristics.

While the high rates charged by a credit card issuer are sometimes fixed in the contract, the fact that the rate charged (nil or the high rate) depends on how quickly the customer repays the amount drawn, means that the rate can be thought of as 'floating', even if it does not vary with a benchmark rate of interest. This is important since otherwise it would be necessary to assess the effective interest rate on initial recognition and keep this fixed unless the facility is derecognised, ignoring any changes in customer behaviour.

Applying this principle, for a credit card customer that is a 'transactor', it would not be appropriate to discount expected credit losses (i.e., the lender applies an interest rate of nil). On the other hand, for a revolver, the high rate of interest is included in the forecast cash flows and in the discount rate.

However, any transactor who goes on to default is likely to begin paying off less than the full amount for a period of time before they default. To estimate the expected credit losses for this scenario, it will be necessary to include any interest that will be charged in this period. A consistent discount rate will then be a blended rate, of nil for the period over which the customer is expected to pay no interest and the high rate over the period in which they will pay the higher rate.

How we see it

In practice, it is likely that credit card issuers will often adopt procedures to discount their expected credit losses that may be less sophisticated than set out above, due to operational constraints and because the objective of IFRS 9 is to discount expected credit losses at an approximation of the effective interest rate. However, it is necessary to understand what is theoretically required by the standard in order to be able to assess whether a pragmatic approach is a reasonable approximation when determining the discount rate.

12.5 Determining significant increases in credit risk

As already mentioned in section 12.2 above, at its April 2015 meeting, the IFRS Transition Resource Group for Impairment of Financial Instruments discussed the starting reference date when assessing significant increases in credit risk for a portfolio of revolving credit facilities. There will typically be a diverse customer base, ranging from long-standing customers who have been with the bank for many years, to new customers who have only recently opened an account. IFRS 9's general rule is that the starting reference date is the date of original recognition. Consequently, the date of initial recognition for this purpose is the date the facility was issued and this is only changed if there has been a derecognition of the original facility. As discussed in section 12.2 above, it is not altogether clear what would qualify as a derecognition within the context of the revolving facility exception. If the lender derecognises a facility at the end of its contractual term and recognises a new one when it decides to renew or extend credit, consistent with the Basis for Conclusions, it would be consistent to assess if there has been a significant increase in credit risk from when the current facility was first recognised. [IFRS 9.BC5.260]. Similarly, it may make sense to use the date that the limit was increased if a facility is now far larger than would have been granted on original recognition. There is also a view that the credit risk on the date that the facility was last increased may be a useful proxy for the credit risk on the date of original recognition. There is a particular challenge on transition to IFRS 9, since entities may have limited data on the credit risk at the date of original recognition. (See section 5.9 above).

However, as discussed in section 12.2 above, another view is that only a reduction or cancellation of the facility would lead to the revolving facility being derecognised. In some circumstances, issuing a new card may be indicative that the original facility has been derecognised (e.g., replacement of a student credit card with a new credit card upon graduation), but in other cases, this may be a purely operational process and thus would not indicate that a new facility has been issued.

The IFRS Transition Resource Group for Impairment of Financial Instruments did not conclude further on this issue and it was not discussed in the IASB's webcast on 16 May 2017. Consequently, at the date of writing this issue had not been resolved.

13 Intercompany loans

For those entities that prepare separate IFRS financial statements, one of the challenges in complying with the IFRS 9 impairment requirements is the application to intercompany loans to members of the same group.

The two most common difficulties faced are the paucity of data to calculate the expected credit losses and the possibility that intercompany loans are either undocumented, or not documented in accordance with the substance of the arrangement. For instance, it is possible that a group entity is financed entirely by debt rather than partly through equity, so that the substance of the loan (at least in part) may be closer to an equity investment in that entity.

Although not explicitly stated, it is clear from IFRS 9 that the recognition of a loss allowance involves a debit to profit or loss (IFRS 9.5.5.8). There is no exception for intercompany loans. Therefore, it needs to be stressed that any expected credit losses measured on a loan to a group entity will require a charge to profit or loss. For instance, the expected credit loss on a loan to a subsidiary will result in an impairment expense and it cannot be capitalised as part of the investment in the subsidiary.

13.1 Scope of intercompany loans under IFRS 9

All intercompany loans measured at amortised cost or fair value through other comprehensive income are in the scope of the expected credit loss requirements (see Chapter 44). Paragraph 2.1(a) of IFRS 9 scopes out of the standard, interests in subsidiaries accounted for in accordance with IAS 27 *Separate Financial Statements* and IAS 27.10 allows investments in subsidiaries to be accounted for at cost as an alternative to applying IFRS 9. For such investments, impairment would be calculated applying IAS 36 *Impairment of Assets*. 'Investments' are not defined in IAS 27. Although IAS 27 is usually read to refer to investments in shares, an argument might be made that it can also cover intercompany arrangements which are, in substance, capital investments. However, in its September 2016 meeting, the IFRS IC seem to have ruled against this. The IFRS Interpretations Committee discussed the interaction of IFRS 9 and IAS 28 *Investments in Associates and Joint Ventures* where a loan is regarded as part of 'long-term interests that, in substance, forms part of the entity's net investment' as set out in IAS 28.38, which gives as an example, "an item for which settlement is neither planned nor likely to occur in the foreseeable future". The IFRS IC concluded that although a loan is considered as 'in substance part of the investment', for the purposes of allocating losses in IAS 28, it is still in the scope of IFRS 9 as it is not 'an investment' as mentioned in scope IFRS 9.2.1(a) and, except for the allocation of losses, is not accounted for using the equity method. Since then, in October 2017, the IASB amended IAS 28 to clarify that IFRS 9 applies to long term interests in associates and joint ventures.

The IFRS IC discussion was in the context of IAS 28 and not IAS 27. It is perhaps relevant that IFRS 9 in its scope paragraph refers to 'interests' in subsidiaries, rather than 'investments', although IAS 27 itself uses 'investments'. IAS 27 also allows investments to be at cost, rather than accounted for using the equity method. However, it would probably be difficult to sustain an argument that 'investments' as used in IAS 27, encompasses loans which are, in substance, part of the net investment, when the IFRS IC has concluded that the same term in IAS 28 does not.

On balance, an undocumented interest free loan to a subsidiary, when there is no expectation of repayment, may be better characterised for accounting purposes as a capital contribution. If this is the case, then it ought to be documented as such and then it may be measured at cost under IAS 27 and subject to the impairment requirements of IAS 36, rather than those of IFRS 9. The amendment of a loan (if previously documented as such) to a capital contribution would be similar to a forgiveness of the debt and therefore, as already mentioned above, may have (or be constrained by) tax implications and may only be capable of being repaid in the future if there are adequate distributable profits.

In addition, there might often be cases where the contractual terms of an intercompany loan which is not 'on demand' are determined to be 'off-market' (e.g., interest-free or below-market rate). In such cases, a portion is highly likely to be accounted for as a capital contribution within the scope of IAS 27, depending on the facts and circumstances. That being the case, the remaining portion would likely be within the scope of IFRS 9 (IFRS 9.B5.1.1 and B5.1.2), in which case measurement at amortised cost or fair value through other comprehensive income would require the financial instrument to pass the IFRS 9 solely payment of principal and interest criterion as otherwise it would need to be measured at fair value through profit and loss.

13.2 Intercompany loans repayable on demand

Assuming the intercompany loan meets the solely payment of principal and interest and business model criteria and is measured either at amortised cost or fair value through other comprehensive income, according to IFRS 9.5.5.19, the maximum period to consider when measuring expected credit losses is the maximum contractual period over which the entity is exposed to credit risk, even if a longer period is consistent with business practice. However, it would be inconsistent to base the period on the lender's ability to call the debt without also evaluating the probability of default based on the assumption that the debt will be called.

If a loan is repayable on demand, the period over which losses are calculated would normally be no more than 24 hours. If the borrowing group entity is able to repay the loan when demanded, the probability of default would usually be very small and the expected credit loss is likely to be immaterial. However, this treatment would not be appropriate for a loan that may be documented as on demand, but in substance provides long term finance (see Chapter 9). The borrowing group entity would be unable to repay the loan if it is called at short notice, because it does not currently have access to the means to repay it or to other sources of financing, if the loan is called, the probability of default would be high and close to 100% if the entity could not repay it.

How we see it

The lender would be entitled to look to the manner of recovery of the amount due in calculating the loss given default, which may mean that it would allow the subsidiary a number of years to accumulate the funds to repay the loan. In instances where the lender expects to recover the full amount of the loan, the expected credit loss will be limited to the effect of discounting of the loan amount over the recovery period and if the loan is interest free, i.e., the effective interest rate is 0%, then there will be no impairment loss. In addition, the lender group entity will also need to consider the staging of these loans, which will require judgement (see section 6 above).

13.3 Determining the expected credit losses of intercompany loans

The Application Guidance to IFRS 9 provides a list of qualitative factors that are relevant in assessing changes in credit risk, all of which may be applicable to assessing whether a significant increase in credit risk has occurred on an intercompany loan (see section 6.2.1 above). Compared to most loans to third parties, a lender within a group is likely to have access to much more qualitative and quantitative information about the credit risk of the borrower. Consequently, the staging assessment is likely to be much better informed than for a third-party loan and will be, primarily, a qualitative exercise. In many cases, it will be reasonably clear whether there has been a significant increase in credit risk since the inception of the loan, although judgement will still be required to determine whether it is 'significant'. Circumstances that indicate a significant increase in credit risk may include a significant change in the business, financial or economic conditions, or regulatory, economic or technological environment in which the borrower operates, declining revenues and margins, or capital deficiencies. Any of these changes are likely to have a significant impact on the entity's ability to meet its debt obligations. [IFRS 9.B5.5.17(f), IFRS 9.B5.5.17(g), IFRS 9.B5.5.17(i)].

Also, the credit risk on a loan depends in part on the level of loss absorbing equity of the borrowing entity. For those intercompany loans between fellow subsidiaries that are explicitly guaranteed by a parent, the expected credit loss may be much lower than those without a parental guarantee. Also, if the parent is listed and the guarantee is integral to the loan, the expected loss will normally be equal to the parent's probability of default multiplied by its loss given default. That is because the parent will usually be expected to ensure, if it can do so, that its subsidiary will not default (and the subsidiary is likely to default if the parent does). It will often be much easier to calculate an expected credit loss based on a parent probability of default and loss given default since there may be market quoted bond spreads, credit default swap spreads and credit ratings to draw upon. Therefore, it may be advisable to formally document guarantee arrangements between a parent and subsidiary when this is already the implicit basis on which the loan was entered into. Another scenario could be that the parent has no activities other than acting as a holding entity, in which case its probability of default will be closely aligned with that of its subsidiaries. There could also be situations where the subsidiary can be expected to survive even if the parent defaults.

How we see it

To the extent that the lender is the parent, it cannot, for its own accounting purposes, rely on guarantees given by itself. However, any group entity that does provide a guarantee will need to measure its exposure to the guarantee, hence the existence of a guarantee does not remove the challenge of calculating the probability of default and loss given default of the subsidiary. In general, the fact that a group intends to ensure that a subsidiary will never default does not eliminate the risk posed by that subsidiary's activities or remove the need for an expected credit loss allowance.

If there are cross-company guarantees within the group relating to loans from external parties of the group, each entity affected by the cross-company guarantee arrangement needs, for the calculation of expected credit losses in its standalone financial statements to factor in the cross-company guarantees in place (see section 11.4 above).

14 Presentation of expected credit losses in the statement of financial position

IFRS 9 uses the term 'loss allowance' throughout the standard as an umbrella term for expected credit losses that are recognised in the statement of financial position. However, that umbrella term leaves open the question of how those expected credit losses are presented in that statement. Their presentation differs by the type of the credit risk exposures that are in scope of the impairment requirements. [IFRS 9 Appendix A]. This section explains how presentation applies in the different situations.

Any adjustment to the loss allowance balance due to an increase or decrease of the amount of expected credit losses recognised in accordance with IFRS 9, is reflected in profit or loss in a separate line as an impairment gain or loss. [IAS 1.82(ba), IFRS 9.5.5.8, IFRS 9 Appendix A].

14.1 Allowance for financial assets measured at amortised cost, contract assets and lease receivables

Expected credit losses on financial assets measured at amortised cost, lease receivables (see Chapter 24) and contract assets (see Chapter 28) are presented as an allowance, i.e., as an integral part of the measurement of those assets in the statement of financial position.

Unlike the requirement to show impairment losses as a separate line item in the statement of profit or loss, there is no similar consequential amendment to IAS 1 to present the loss allowance as a separate line item in the statement of financial position. [IAS 1.82(ba)].

It is clear from IFRS 9 that the definition of amortised cost of a financial asset is after adjusting for any loss allowance and hence, the loss allowance would reduce the gross carrying amount in the statement of financial position (which is why an allowance is sometimes referred to as a contra asset account). [IFRS 9 Appendix A]. Accordingly, financial assets measured at amortised cost, contract assets and lease receivables are presented net of the loss allowance at their amortised cost in the statement of financial position.

Frequently asked questions

Question 14-1: Whether an entity is required to present the loss allowance for financial assets measured at amortised cost (or trade receivables, contract assets or lease receivables) separately in the statement of financial position?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 11 December 2015 - Agenda paper no. 10)

At the IFRS Transition Resource Group for Impairment of Financial Instruments meeting in December 2015 (see section 1.4 above), the IFRS Transition Resource Group for Impairment of Financial Instruments members first noted that irrespective of how the loss allowance is presented or how it is included in the measurement of the financial instrument, IFRS 7 contains disclosure requirements pertaining to the loss allowance for all financial instruments within the scope of the IFRS 9 impairment requirements. The IFRS Transition Resource Group for Impairment of Financial Instruments members also noted that, in contrast to the case of financial assets measured at fair value through other comprehensive income, neither IFRS 9 nor IFRS 7 contains any specific requirements regarding the presentation of the loss allowance for financial assets measured at amortised cost (or trade receivables, contract assets or lease receivables) on the face of the statement of financial position. In accordance with the general requirements of IAS 1, the financial statements should fairly present the financial position of an entity. However, the IFRS Transition Resource Group for Impairment of Financial Instruments members noted that IAS 1.54 does not list the loss allowance as an amount that is required to be separately presented on the face of the statement of financial position.

14.1.1 Write-off

IFRS 9 provides guidance on when the allowance is used, i.e., when it is applied against the gross carrying amount of a financial asset. This occurs when there is a write-off on a financial asset, which happens when the entity has no reasonable expectations of recovering the contractual cash flows on a financial asset in its entirety or a portion thereof. A write-off is considered a derecognition event. [IFRS 9.5.4.4, IFRS 9.B3.2.16(r)].

For example, a lender plans to enforce the collateral on a loan and expects to recover no more than 30% of the value of the loan from selling the collateral. If the lender has no reasonable prospects of recovering any further cash flows from the loan, it should write off the remaining 70%. [IFRS 9.B5.4.9]. The example given in IFRS 9 demonstrates that write-offs can be for only a partial amount instead of the entire gross carrying amount.

Some examples of circumstances which could lead to full or partial write off are where:

- Individually assessed loans that are secured, are written-off after the receipt of the proceeds from the realisation of the security, and there is no expectation that any further amounts will be recovered by any other means

Or

- A borrower is declared bankrupt or insolvent, especially in the case of unsecured exposures where the liquidator or administrator has indicated that there are not sufficient resources available to satisfy the unsecured creditors

In practice, for collectively assessed loans, write-offs may also be effected within certain time frames post-default of a financial asset, for example unsecured loans may be written-off within a number of years after default.

The Illustration below shows how partial write-offs may be determined for a loan in stage 3.

Illustration 14-1: Partial write-offs for a loan in stage 3

As at 31 December 20X2, the lender has an impaired loan in stage 3 and determines that it has a 75% probability of recovering nothing and a 25% probability of recovering 20% of the value of the loan. Ignoring discounting, the overall expected credit loss would be 95% (i.e., $100\% - (75\% \times 0\% + 25\% \times 20\%)$). The probability-weighted expectation is therefore a recovery of 5% of the loan balance.

As there is still 25% probability of recovering 20% of the value of the loan, the lender writes-off a partial amount of the loan, i.e., 80% of the loan balance, leaving 20% of the loan on the balance sheet and an expected credit loss of 15%.

Because IFRS 9 requires a loan to be written off in part when it is no longer expected that a portion of the amount due will be collected, the loan may be written off in partial amounts as stage 3 progresses. This means that there may be no single 'write-off point' but instead a continuum; e.g., a loan may initially be written off 50%, then 80% and finally 100%.

Practice varies in terms of write-off and is sometimes dependent on the influence of prudential regulators.

Write-off requirements in IFRS 9 are considered at each reporting date and are not delayed until some arbitrary past due date has been reached. On the other hand, if collection efforts continue and have some possibility of success, total write-off would also seem to be inappropriate.

If the amount of loss on write-off is greater than the accumulated loss allowance, the difference will be an additional impairment loss. In situations where a further impairment loss occurs, the question has arisen as to how it is presented: simply as a loss in profit or loss with a credit directly to the gross carrying amount; or first, as an addition to the allowance that is then applied against the gross carrying amount. The difference between those alternatives is whether the additional impairment loss flows through the allowance, showing up in a reconciliation of the allowance as an addition and a use (i.e., a write-off), or whether such additional impairment amounts bypass the allowance. The IASB's original 2009 exposure draft (see section 1.1 above) explicitly mandated that all write-offs could only be debited against the allowance, meaning that any direct write-offs against profit or loss without flowing through the allowance were prohibited.⁴⁰ IFRS 9 does not include any similar explicit guidance on this issue (see Chapter 46 in relation to presentation of modification losses).

Similarly, IFRS 9 does not provide guidance on accounting for subsequent recoveries of a financial asset. Arguably, there would be a higher threshold when recognising an asset that has been previously written-off and this is likely to be when cash is received rather than when the criteria for write-off are no longer met. It might also be argued that such recoveries are often not significant, as write-off only occurs when there is no reasonable expectations of recovering the contractual cash flows. The occurrence of large recoveries subsequent to the recognition of total write-offs will give entities an indication to reconsider their approaches to future write-offs.

⁴⁰ Exposure Draft [ED/2009/12: Financial Instruments: Amortised Cost and Impairment](#), IASB, November 2009, para. B23. Available on the IFRS Foundation's website.

As the nature of recoveries are similar to reversals of impairment, it makes sense to present such recoveries in the impairment line in profit or loss as it would provide useful and relevant information to the users of the financial statements. [IAS 1.82(ba)].

How we see it

IFRS 7 requires an entity to disclose its policies in relation to write-offs and also, the amounts written off during the period that are still subject to enforcement activity (see section 15 below and Chapter 50). It is noted that there is a tension between this requirement and the criteria in IFRS 9 for write-off, since it may be difficult to argue that there is no reasonable expectation of recovering the contractual cash flows if the loan is still subject to enforcement activity.

14.1.2 Presentation of the interest revenue, gross carrying amount, amortised cost, expected credit loss expense and expected credit loss allowance for credit-impaired assets

For financial assets that are not purchased or originated credit-impaired financial assets but subsequently have become credit-impaired, i.e., moved to stage 3, in subsequent reporting periods the interest revenue is calculated by multiplying the effective interest rate by the net amortised cost, i.e., the gross carrying amount of the financial asset net of the expected credit loss allowance. [IFRS 9.5.4.1(b)]. However, the application of the effective interest rate to the amortised cost of the financial asset applies only to the calculation and presentation of interest revenue. The Basis for Conclusions confirms that this does not affect the measurement of the loss allowance. [IFRS 9.BC5.75]. As long as the asset was not credit-impaired on initial recognition, the effective interest rate is based on the contractual cash flows, excluding expected credit losses and this does not change when the asset becomes credit-impaired. [IFRS 9.B5.4.4, IFRS 9 Appendix A]. Consequently, the calculation of the gross carrying amount and the expected credit loss allowance, as disclosed in the notes to the financial statements, are not affected by the recognition of interest revenue moving from a gross to a net basis.

Frequently asked questions

Question 14-2: How the gross carrying amount and loss allowance for credit-impaired financial instruments that are not purchased or originated credit-impaired and that are measured at amortised cost should be calculated?

(IFRS Transition Resource Group for Impairment of Financial Instruments meeting 11 December 2015 - Agenda paper no. 9)

This was confirmed at a meeting of the IFRS Transition Resource Group for Impairment of Financial Instruments in December 2015 (see section 1.4 above), when a question was raised on how the disclosed figures for the gross carrying amount and loss allowance should each be calculated. The Illustration below is based on the IFRS Transition Resource Group for Impairment of Financial Instruments discussion but has been amended to reflect unpaid accrued interest in the gross carrying amount.

Illustration 14-2: Disclosing the gross carrying amount and loss allowance for credit-impaired financial assets that are not purchased or originated credit-impaired

The Bank originated a loan on 1 January 20X2, with an amortised cost of CU100 and an effective interest rate of 10% per annum. On 31 December 20X2, the loan is considered to be credit-impaired and so is moved to stage 3, and an impairment allowance is recognised of CU70. Accordingly, the gross carrying amount of the loan is now CU110 and the amortised cost is now CU40. During 20X3, no cash is received, and on 31 December 20X3, there is no change in the expected cash flows. Accordingly, the amortised cost becomes CU44 (being $CU40 + (CU40 \times 10\%)$). Three different ways could be used to reflect the changes in the net amortised cost in the gross carrying amount and the loss allowance. In Approach A, interest continues to be accrued in the measurement of the gross carrying amount at 10%, in Approach B, the interest accrued to the gross carrying amount is only the CU4 recorded in profit or loss, while in Approach C, no interest is added to the gross carrying amount:

Approach	A	B	C
	CU	CU	CU
Gross carrying amount*	121	114	110
Loss allowance	(77)	(70)	(66)
Amortised cost	44	44	44

* The gross carrying amount of CU121 is calculated by adding the effective interest rate of 10% per annum on the 31 December 20X2 gross carrying amount of CU110, i.e., $10\% \times CU110 = CU11$.

The IFRS Transition Resource Group for Impairment of Financial Instruments members appeared to agree that only Approach A is IFRS 9-compliant. Thereby, for assets in stage 3, it is necessary to 'gross up' accrued interest income, to increase both the disclosed gross carrying amount and loss allowance in the notes to the financial statements. Approach A requires the entity to calculate:

- The gross carrying amount by discounting the estimated contractual cash flows (without considering expected credit losses) using the original effective interest rate
- The loss allowance by discounting the expected cash shortfalls using the original effective interest rate

Depending on the legal form of the loan, we assume that once interest is no longer contractually due, for instance when the bank moves to take possession of collateral, there would be no need to continue to make these gross up entries.

Moreover, the IFRS Transition Resource Group for Impairment of Financial Instruments did not consider the interaction between the recognition of interest income and the requirement to write off all or a proportion of the gross financial asset if there is no reasonable expectation of recovering the associated contractual cash flows. If there is no reasonable expectation that all of the contractual interest will be paid, then the lender presumably does not follow Approach A. Instead, a portion of the gross asset would be written off against the allowance, depending on the expectations of recovery. This could result in a lender reporting numbers closer to those in Approach B. By writing off accrued interest where there is no reasonable expectation of recovery, it may be possible to align the amounts disclosed for stage 3 loans under IFRS 9 with the figures that banking regulators require to be disclosed for non-performing loans.

The IASB is of the view that, conceptually, an entity assesses whether financial assets have become credit-impaired on an ongoing basis, thus, altering the presentation of interest revenue as the underlying economics change. However, the IASB noted that such an approach would be unduly onerous for preparers to apply. Thus, the IASB decided that an entity is required to make the assessment of whether a financial asset is credit-impaired at the reporting date and then change the interest calculation from the beginning of the following reporting period. [IFRS 9.BC5.78]. This reference to reporting period is therefore in the context of a practical expedient.

How we see it

'Reporting period' includes both annual (full IFRS) and interim (IAS 34 *Interim Financial Reporting*) financial reporting periods for which financial statements are produced in accordance with IFRS.

'Subsequent reporting period' therefore refers to the next interim or annual reporting period, whichever comes sooner, where an entity is required to change between gross and net interest income presentation if the financial asset has become (or ceased to be) credit-impaired at the reporting date.

If entities voluntarily perform their staging and interest calculations more frequently than their reporting periods, this is not contrary to the objective of this requirement, provided that the approach is applied consistently. Arguably, if an entity is able to change the interest calculation earlier than the subsequent reporting date, then this would be a timelier adjustment and reflection of the interest revenue. However, this is not what IFRS 9 requires.

How we see it

An entity *may* assess whether a financial asset has become (or ceased to be) credit-impaired more frequently than at its reporting dates. If it does so, any resulting changes between gross and net interest income presentation will occur more frequently than at its next reporting period. Such an assessment may be made at the end of the period normally used by the entity for internal reporting purposes and when impairment is normally assessed, as opposed to applying an ad hoc period for this purpose. The timing of these assessments should be evenly spaced and consistently applied.

Frequently asked questions

Question 14-3: How an entity presents amounts recognised in the statement of profit or loss when a credit-impaired financial asset is subsequently cured (i.e., paid in full or no longer credit-impaired)?

(IFRS IC meeting 27 November 2018 and 5 March 2019 - Agenda paper no. 7 and no. 13 respectively)

At its meeting in November 2018 and March 2019, the IFRS IC noted that diversity in practice had arisen.

When a financial asset becomes credit-impaired, application of the effective interest rate to the amortised cost of the financial asset results in a difference between:

- (a) The interest that would be calculated by applying the effective interest rate to the gross carrying amount of the credit-impaired financial asset
- (b) The interest revenue recognised for that asset

If the financial asset cures and the full amount of interest income is subsequently received, how is this difference recorded? The IFRS IC concluded that, in the statement of profit or loss, an entity is required to present the difference as a reversal of impairment losses rather than as interest revenue following the curing of a credit-impaired financial asset.

In reaching its conclusion, the IFRS IC noted that IFRS 9.5.5.8 requires an entity to "recognise in profit or loss, as an impairment gain or loss, the amount of expected credit losses (or reversal) that is required to adjust the loss allowance at the reporting date to the amount that is required to be recognised in accordance with this Standard."

Applying IFRS 9.5.5.8, an entity recognises in profit or loss as a reversal of expected credit losses the adjustment required to bring the loss allowance to the amount that is required to be recognised in accordance with IFRS 9 (zero if the asset is paid in full). The amount of this adjustment includes the effect of the unwinding of the discount on the loss allowance during the period that the financial asset was credit-impaired. This means that the reversal of impairment losses may exceed the impairment losses recognised in profit or loss over the life of the asset.

On 22 July 2019, the IASB staff released an educational webinar which included an example explaining the accounting required to reflect the curing of a credit-impaired financial asset, consistent with the IFRS IC tentative agenda decision. This is shown in the Illustration below with amounts rounded to the nearest CU1 and 1%.

Illustration 14-3: Presentation of the interest revenue, gross carrying amount, amortised cost, expected credit loss expense and expected credit loss allowance for when assets move from stage 2 to stage 3 and vice versa

On 1 January 20X2, an entity originates a 5-year loan with a principal amount of CU100 and annual instalments of CU26 payable annually on 31 December, which results in an effective interest rate of 10%.

The entity measures expected credit losses for the first time at the first reporting date as at 31 December 20X2 after initial recognition. As at 31 December 20X2, the credit risk on the loan has increased significantly since initial recognition (i.e., the loan has moved from stage 1 to stage 2) and the entity recognised lifetime expected credit losses of CU66. For the reporting period to 31 December 20X2, the interest revenue would be calculated by applying the 10% effective interest rate to the gross carrying amount of the loan of CU100, i.e., CU10. The annual instalment of CU26 was received.

As at 31 December 20X3, the next annual instalment had not been paid and the loan is assessed to be credit-impaired (i.e., stage 3). For the reporting period to 31 December 20X3, the interest revenue would be calculated by applying the 10% effective interest rate to the gross carrying amount of the loan of CU84, i.e., CU8. To simplify the example, there is no change in the expected shortfalls in contractual cash flows between 31 December 20X2 and 31 December 20X4 even though the loan has deteriorated to stage 3. An impairment loss of CU7 is recognised for the unwinding of the discount based on the effective interest rate determined at initial recognition of 10%, in order to reflect the passage of time, i.e., 10% effective interest rate on the CU66 impairment loss allowance.

For the year to 31 December 20X4, the interest revenue would be calculated by applying the 10% effective interest rate to the amortised cost of the loan of CU19, i.e., CU2, instead of the gross carrying amount. Both the gross carrying amount and expected credit loss allowance are discounted and therefore, need to reflect the effect of the unwinding of the discount. The gross carrying amount needs to increase by CU9 and the expected credit loss allowance needs to increase by CU7, based on the effective interest rate determined at initial recognition of 10%, in order to reflect the passage of time. As interest revenue of CU2 has been recognised, both the gross carrying amount and expected credit loss allowance need to increase by an additional CU7 (reflected as unwinding of the discount).

To simplify the example, it is assumed that as at 1 January 20X5, the entity received the contractual amount due in full of CU101. CU80 of impairment losses are released as a credit to the impairment expense. In this example the impairment credit exceeds the impairment losses previously recognised in profit or loss over the life of the asset (CU66 + CU7 = CU73) due to the effect of the unwinding of the discount on the loss allowance during the period that the financial asset was credit-impaired.

	31 December 20X2	31 December 20X3	31 December 20X4	31 December 20X5
	Stage 2	Stage 3	Stage 3	Fully repaid
	CU	CU	CU	CU
Statement of financial position				
Gross carrying amount				
As at 1 Jan	100	84	92	101
Interest accrued (i.e., effective interest rate) on the gross carrying amount (stage 2) or amortised cost in the next reporting period (stage 3)	10	8	2	-
Unwinding of discount	-	-	7	-
Repayment	(26)	-	-	(101)
As at 31 Dec	84	92	101	-

Expected credit losses allowance				
<i>As at 1 Jan</i>	-	66	73	80
<i>Impairment</i>	66	-	-	(80)
<i>Unwinding of discount</i>	-	7	7	-
<i>As at 31 Dec</i>	66	73	80	-
Amortised cost				
<i>As at 1 Jan</i>	100	18	19	21
<i>As at 31 Dec</i>	18	19	21	-
Statement of profit or loss				
<i>Interest revenue</i>	10	8	2	-
<i>Impairment loss/(reversal)</i>	66	7	-	(80)

14.2 Provisions for loan commitments and financial guarantee contracts

In contrast to the presentation of impairment of assets, expected credit losses on loan commitments and financial guarantee contracts are presented as a provision in the statement of financial position, i.e., as a liability. [IFRS 9 Appendix A].

Extract from IFRS 7

B8E For loan commitments and financial guarantee contracts the loss allowance is recognised as a provision. An entity should disclose information about the changes in the loss allowance for financial assets separately from those for loan commitments and financial guarantee contracts. However, if a financial instrument includes both a loan (ie financial asset) and an undrawn commitment (ie loan commitment) component and the entity cannot separately identify the expected credit losses on the loan commitment component from those on the financial asset component, the expected credit losses on the loan commitment should be recognised together with the loss allowance for the financial asset. To the extent that the combined expected credit losses exceed the gross carrying amount of the financial asset, the expected credit losses should be recognised as a provision.

[IFRS 7.B8E].

For financial institutions that offer credit facilities, commitments may often be partially drawn down, i.e., an entity may have a facility that includes both a loan (a financial asset) and an undrawn commitment (a loan commitment). If the entity cannot separately identify the expected credit losses attributable to the drawn amount and the undrawn commitment, IFRS 7 requires an entity to present the provision for expected credit losses on the loan commitment together with the allowance for the financial asset. IFRS 7 states, further, that if the combined expected credit losses exceed the gross carrying amount of the financial asset, then the expected credit losses should be recognised as a provision (see extract above).

14.3 Accumulated impairment amount for debt instruments measured at fair value through other comprehensive income

Rather than presenting expected credit losses on financial assets measured at fair value through other comprehensive income as an allowance, this amount is presented as the 'accumulated impairment amount' in other comprehensive income. This is because financial assets measured at fair value through other comprehensive income are measured at fair value in the statement of financial position and the accumulated impairment amount cannot reduce the carrying amount of these assets (see section 9 above for further details). [IFRS 9.4.1.2A, IFRS 9.5.5.2, IFRS 9 Appendix A].

15 Disclosures

The credit risk disclosure requirements have expanded significantly and are supplemented by some detailed implementation guidance. The disclosure requirements in relation to the IFRS 9 expected credit losses model are dealt with in more detail in Chapter 50, and this section provides only a high level summary.

The credit risk disclosure requirements will aim to enable users of financial statements to understand better an entity's credit risk management practices, its credit risk exposures, expected credit losses estimates and changes in credit risks. [IFRS 7.35B]. In order to meet this objective, an entity will need to disclose both quantitative and qualitative information that includes the following:

- Inputs, assumptions and estimation used (and any changes) to determine significant increases in credit risk of financial instruments, including the application of the low credit risk and more than 30 days past due operational simplifications (see section 6 above). [IFRS 7.35F(a), IFRS 7.35G(a)(ii), IFRS 7.35G(c)].
- Inputs, assumptions and techniques used (and any changes) in measuring 12-month and lifetime expected credit losses, including the definition of default and the incorporation of forward-looking information (see section 5 above). [IFRS 7.35F(b), IFRS 7.35G(a)(i), IFRS 7.35G(b), IFRS 7.35G(c), IFRS 7.B8A]. How the financial instruments were grouped if the measurement of expected credit losses was performed on a collective basis (see section 6.5 above). [IFRS 7.35F(c)].
- How collateral and other credit enhancements affect the estimate of expected credit losses, including a description of the nature and quality of collateral held and quantitative information about the collateral for financial assets that are credit-impaired (see sections 5.8.1 and 6.1.1 above). [IFRS 7.35K, IFRS 7.B8F, IFRS 7.B8G].
- A reconciliation of the opening and closing balance of the loss allowance and explanations of the changes. This disclosure is required to be shown separately for: [IFRS 7.35H]
 - Financial instruments that are measured using 12-month expected credit losses
 - Those that are measured using lifetime expected credit losses
 - Those that are credit-impaired on initial recognition
 - Those that are subsequently credit-impaired
 - Trade receivables, contract assets and lease receivables measured under the simplified approach
- Explanation of how significant changes in the gross carrying amount of financial instruments during the period contributed to changes in the loss allowance. [IFRS 7.35I].
- Inputs, assumptions and techniques used (and any changes) to determine whether a financial asset is credit-impaired (see sections 3.1 and 3.3 above). [IFRS 7.35F(d), IFRS 7.35G(a)(iii), IFRS 7.35G(c)].
- For modified financial assets (see section 8 above): [IFRS 7.35F(f), IFRS 7.B8B, IFRS 7.35J]
 - The credit risk management practices (how an entity determines that a financial asset that is modified when its loss allowance was measured based on lifetime expected credit losses has improved to the extent that its allowance can now be reduced to 12-month expected credit losses, and how an entity monitors the extent to which such a loss allowance are subsequently brought back to lifetime expected credit losses).
 - The amortised cost before the modification and the net modification gain or loss recognised during the period for modified financial assets with a loss allowance measured at lifetime expected credit losses.
 - The gross carrying amount of those modified financial assets for which the loss allowance has changed from lifetime to 12-month expected credit losses during the period.
 - Quantitative information that will assist users to understand any subsequent increase in credit risk, including information about modified financial assets for which the loss allowance has reverted from 12-month expected credit losses to lifetime expected credit losses.

- The entity's credit risk exposure and significant credit risk concentrations, including the gross carrying amount of financial assets and the exposure to credit risk on loan commitments and financial guarantee contracts, by credit risk rating grades or past due status. This disclosure is required to be shown separately for: *[IFRS 7.35M, IFRS 7.B8H, IFRS 7.B8I]*
 - Those instruments that are measured using 12-month expected credit losses
 - Those that are measured using lifetime expected credit losses
 - Those that are credit-impaired on initial recognition
 - Those that are subsequently credit-impaired
 - Trade receivables, contract assets and lease receivables measured under the simplified approach
- The write-off policy and amounts written off during the period that are still subject to enforcement activity (see section 14.1.1 above). *[IFRS 7.35F(e), IFRS 7.35L]*.

In addition, the Enhanced Disclosure Task Force has developed common expected credit losses disclosure practices which are discussed in Chapter 50.

How we see it

The disclosures required by IFRS 7 in respect of expected credit losses are substantial. It is critical for entities to align their credit risk management and financial reporting systems and processes, not only to estimate the loss allowance for expected credit losses, but also to produce a sufficient level of detailed information to meet the disclosure requirements in IFRS 7.

Appendix B - Index of Frequently asked questions

Question 5-1:	What is the maximum period to consider when measuring expected credit losses for a portfolio of mortgage loans with a stated maturity but containing a contractual feature whereby the term is automatically extended subject to the lender's non-objection?	3859
Question 5-2:	Whether, when measuring expected credit losses and when assessing significant increases in credit risk, can an entity use a single forward-looking economic scenario or whether an entity needs to incorporate multiple forward-looking scenarios, and if so how?	3861
Question 5-3:	What is meant by the current effective interest rate used to discount expected credit losses when an entity recognises interest revenue in each period based on the actual floating rate applicable to that period?	3867
Question 5-4:	What is meant by 'part of the contractual terms'?	3869
Question 5-5:	Whether the cash flows expected from a financial guarantee contract or any other credit enhancement can be included in the measurement of expected credit losses if the credit enhancement is required to be recognised separately applying IFRS standards?	3869
Question 5-6:	Whether cash flows that are expected to be recovered in certain circumstances where an entity chooses to sell a defaulted loan to a third-party in order to maximise recovery cash flows could be included in the measurement of expected credit losses?	3874
Question 5-7:	Whether and how to incorporate events and forecasts, when applying the impairment requirements at the reporting date, that occur: (a) After economic forecasts have been made but before the reporting date (b) Between the reporting period end and the date of signing the financial statements	3878
Question 5-8:	Implementation issues related to forward-looking information.	3879
Question 6-1:	Whether in respect of financial instruments with a maturity of 12 months or less there is a requirement to assess significant increases in credit risk?	3881
Question 6-2:	Whether an entity should consider the ability to recover cash flows through the integral financial guarantee contract when assessing whether there has been a significant increase in the credit risk of the guaranteed debt instrument since initial recognition?	3884
Question 6-3:	Whether an entity can use behavioural indicators of credit risk as a proxy for the assessment of significant increases in credit risk since initial recognition?	3896
Question 6-4:	Whether, and if so to what extent, an entity would be required to perform a review to determine whether circumstances still support the use of changes in the 12-month risk of a default occurring as an approximation of changes in the lifetime risk of default occurring?	3903
Question 6-5:	How an entity should determine whether there has been a significant increase in credit risk for a portfolio of loans advanced to customers across broad credit quality bands with identical pricing and contractual terms, for example, retail loans?	3906
Question 7-1:	Whether there is a requirement to measure Expected Credit Losses at dates other than the reporting date, namely the date of derecognition and the date of initial recognition?	3920
Question 8-1:	How to determine the expected credit losses in respect of a modified financial asset if the modification had not resulted in a derecognition but the modified cash flows have been renegotiated in such a way as to represent the cash flows which the lender expects the borrower can repay?	3945
Question 10-1:	How does the lessor account for forgiveness of lease payments before and after the rent concession is granted under IFRS 9 and IFRS 16?	3954
Question 11-1:	Whether the impairment requirements in IFRS 9 must also be applied to other commitments to extend credit?	3956

Question 11-2:	Whether the measurement of expected credit losses for financial guarantee contracts issued should consider future premium receipts due from the holder and, if so, how?	3958
Question 12-1:	Whether multi-purpose credit facilities would fall within the scope of IFRS 9.5.5.20 and whether the general characteristics identified in IFRS 9.B5.5.39 should be considered to be required characteristics, or merely examples of typical characteristics?	3962
Question 12-2:	How future drawdowns should be estimated when a revolving credit facility might not have a specified credit limit in the contract?	3963
Question 12-3:	What is the maximum period to consider when measuring expected credit losses for revolving credit facilities?	3965
Question 12-4:	When does the period start and end in assessing the maximum period when measuring expected credit losses for revolving credit facilities?	3965
Question 12-5:	How to determine the date of initial recognition of a revolving credit facility for the purposes of the assessment of significant increases in credit risk?	3968
Question 12-6:	Whether an exposure in excess of the contractually agreed credit limit could be used when estimating the exposure at default for revolving credit facilities in accordance with IFRS 9 when an entity has a history of allowing customers to exceed their contractually set credit limits?	3970
Question 14-1:	Whether an entity is required to present the loss allowance for financial assets measured at amortised cost (or trade receivables, contract assets or lease receivables) separately in the statement of financial position?	3975
Question 14-2:	How the gross carrying amount and loss allowance for credit-impaired financial instruments that are not purchased or originated credit-impaired and that are measured at amortised cost should be calculated?	3978
Question 14-3:	How an entity presents amounts recognised in the statement of profit or loss when a credit-impaired financial asset is subsequently cured (i.e., paid in full or no longer credit-impaired)?	3979

Appendix C - Defined terms

Extract from IFRS 9

Appendix A

Defined terms

12-month expected credit losses	The portion of lifetime expected credit losses that represent the expected credit losses that result from default events on a financial instrument that are possible within the 12 months after the reporting date.
amortised cost of a financial asset or financial liability	The amount at which the financial asset or financial liability is measured at initial recognition minus the principal repayments, plus or minus the cumulative amortisation using the effective interest method of any difference between that initial amount and the maturity amount and, for financial assets, adjusted for any loss allowance .
contract assets	Those rights that IFRS 15 <i>Revenue from Contracts with Customers</i> specifies are accounted for in accordance with this Standard for the purposes of recognising and measuring impairment gains or losses.
credit-impaired financial asset	<p>A financial asset is credit-impaired when one or more events that have a detrimental impact on the estimated future cash flows of that financial asset have occurred. Evidence that a financial asset is credit-impaired include observable data about the following events:</p> <ul style="list-style-type: none"> (a) significant financial difficulty of the issuer or the borrower; (b) a breach of contract, such as a default or past due event; (c) the lender(s) of the borrower, for economic or contractual reasons relating to the borrower's financial difficulty, having granted to the borrower a concession(s) that the lender(s) would not otherwise consider; (d) it is becoming probable that the borrower will enter bankruptcy or other financial reorganisation; (e) the disappearance of an active market for that financial asset because of financial difficulties; or (f) the purchase or origination of a financial asset at a deep discount that reflects the incurred credit losses. <p>It may not be possible to identify a single discrete event- instead, the combined effect of several events may have caused financial assets to become credit-impaired.</p>
credit loss	<p>The difference between all contractual cash flows that are due to an entity in accordance with the contract and all the cash flows that the entity expects to receive (ie all cash shortfalls), discounted at the original effective interest rate (or credit-adjusted effective interest rate for purchased or originated credit-impaired financial assets).</p> <p>An entity shall estimate cash flows by considering all contractual terms of the financial instrument (for example, prepayment, extension, call and similar options) through the expected life of that financial instrument. The cash flows that are considered shall include cash flows from the sale of collateral held or other credit enhancements that are integral to the contractual terms. There is a presumption that the expected life of a financial instrument can be estimated reliably. However, in those rare cases when it is not possible to reliably estimate the expected life of a financial instrument, the entity shall use the remaining contractual term of the financial instrument.</p>

credit-adjusted effective interest rate	The rate that exactly discounts the estimated future cash payments or receipts through the expected life of the financial asset to the amortised cost of a financial asset that is a purchased or originated credit-impaired financial asset . When calculating the credit-adjusted effective interest rate, an entity shall estimate the expected cash flows by considering all contractual terms of the financial asset (for example, prepayment, extension, call and similar options) and expected credit losses . The calculation includes all fees and points paid or received between parties to the contract that are an integral part of the effective interest rate (see paragraphs B5.4.1-B5.4.3), transaction costs , and all other premiums or discounts. There is a presumption that the cash flows and the expected life of a group of similar financial instruments can be estimated reliably. However, in those rare cases when it is not possible to reliably estimate the cash flows or the remaining life of a financial instrument (or group of financial instruments), the entity shall use the contractual cash flows over the full contractual term of the financial instrument (or group of financial instruments).
effective interest method	The method that is used in the calculation of the amortised cost of a financial asset or a financial liability and in the allocation and recognition of the interest revenue or interest expense in profit or loss over the relevant period.
effective interest rate	The rate that exactly discounts estimated future cash payments or receipts through the expected life of the financial asset or financial liability to the gross carrying amount of a financial asset or to the amortised cost of a financial liability . When calculating the effective interest rate, an entity shall estimate the expected cash flows by considering all the contractual terms of the financial instrument (for example, prepayment, extension, call and similar options) but shall not consider the expected credit losses . The calculation includes all fees and points paid or received between parties to the contract that are an integral part of the effective interest rate (see paragraphs B5.4.1-B5.4.3), transaction costs , and all other premiums or discounts. There is a presumption that the cash flows and the expected life of a group of similar financial instruments can be estimated reliably. However, in those rare cases when it is not possible to reliably estimate the cash flows or the expected life of a financial instrument (or group of financial instruments), the entity shall use the contractual cash flows over the full contractual term of the financial instrument (or group of financial instruments).
expected credit losses	The weighted average of credit losses with the respective risks of a default occurring as the weights.
financial guarantee contract	A contract that requires the issuer to make specified payments to reimburse the holder for a loss it incurs because a specified debtor fails to make payment when due in accordance with the original or modified terms of a debt instrument.
gross carrying amount of a financial asset	The amortised cost of a financial asset , before adjusting for any loss allowance .
impairment gain or loss	Gains or losses that are recognised in profit or loss in accordance with paragraph 5.5.8 and that arise from applying the impairment requirements in Section 5.5.
lifetime expected credit losses	The expected credit losses that result from all possible default events over the expected life of a financial instrument.

loss allowance	The allowance for expected credit losses on financial assets measured in accordance with paragraph 4.1.2, lease receivables and contract assets , the accumulated impairment amount for financial assets measured in accordance with paragraph 4.1.2A and the provision for expected credit losses on loan commitments and financial guarantee contracts .
modification gain or loss	The amount arising from adjusting the gross carrying amount of a financial asset to reflect the renegotiated or modified contractual cash flows. The entity recalculates the gross carrying amount of a financial asset as the present value of the estimated future cash payments or receipts through the expected life of the renegotiated or modified financial asset that are discounted at the financial asset's original effective interest rate (or the original credit-adjusted effective interest rate for purchased or originated credit-impaired financial assets) or, when applicable, the revised effective interest rate calculated in accordance with paragraph 6.5.10. When estimating the expected cash flows of a financial asset, an entity shall consider all contractual terms of the financial asset (for example, prepayment, call and similar options) but shall not consider the expected credit losses , unless the financial asset is a purchased or originated credit-impaired financial asset , in which case an entity shall also consider the initial expected credit losses that were considered when calculating the original credit-adjusted effective interest rate .
past due	A financial asset is past due when a counterparty has failed to make a payment when that payment was contractually due.
purchased or originated credit-impaired financial asset	Purchased or originated financial asset(s) that are credit-impaired on initial recognition.
transaction costs	Incremental costs that are directly attributable to the acquisition, issue or disposal of a financial asset or financial liability (see paragraph B5.4.8). An incremental cost is one that would not have been incurred if the entity had not acquired, issued or disposed of the financial instrument.

Appendix D - Illustrative Examples included in IFRS 9 and references

Assessing significant increases in credit risk since initial recognition		
Example 1	Significant increase in credit risk	Section 6.2.4, Illustration 6-2
Example 2	No significant increase in credit risk	Section 6.2.4, Illustration 6-3
Example 3	Highly collateralised financial asset	Section 6.1.1, Illustration 6-1
Example 4	Public investment-grade bond	Section 6.4.1, Illustration 6-5
Example 5	Responsiveness to changes in credit risk	Section 6.5.3, Illustration 6-10 and Illustration 6-11
Example 6	Comparison to maximum initial credit risk	Section 6.4.5, Illustration 6-8
Example 7	Counterparty assessment of credit risk	Section 6.4.4, Illustration 6-7
Recognition and measurement of expected credit losses		
Example 8	12-month expected credit loss measurement using an explicit 'probability of default' approach	Not Included
Example 9	12-month expected credit loss measurement based on loss rate approach	Section 5.4.2, Illustration 5-3
Example 10	Revolving credit facilities	Section 12.2.2
Example 11	Modification of contractual cash flows	Section 8.2, Illustration 8-1
Example 12	Provision matrix	Section 10.1, Illustration 10-1
Example 13	Debt instrument measured at fair value through other comprehensive income	Section 9.1, Illustration 9-1
Example 14	Interaction between the fair value through other comprehensive income measurement category and foreign currency denomination, fair value hedge accounting and impairment	Section 9.2, Illustration 9-2

Chapter 48

Financial instruments: Derecognition

Contents

Overview	3998
1 Interaction with other IFRS accounting standards	3999
2 Definitions and scope	4000
2.1 Definitions	4000
2.2 Scope	4002
3 Derecognition - financial assets	4003
3.1 Background	4003
3.2 Decision tree	4003
3.2.1 Importance of applying tests in sequence	4005
3.3 Consolidation of all subsidiaries (including any SPEs)	4005
3.4 Determination of whether the derecognition principles apply to a part or all of an asset or groups of assets	4007
3.4.1 Transfer of asset (or part of asset) for only part of its life	4008
3.4.2 Derecognition of groups of similar financial assets	4008
3.4.2.A The IASB's view and the IFRS IC's tentative conclusions	4009
3.4.2.B What are 'similar assets'?	4010
3.5 Have the contractual rights to cash flows from the asset expired?	4011
3.5.1 Renegotiation of the terms of an asset	4011
3.5.2 IFRS IC discussions on asset restructuring in the context of Greek government debt	4013
3.5.3 Novation of contracts to intermediary counterparties	4013
3.5.4 Interbank Offered Rate (IBOR) Reform	4014
3.5.5 Write-offs	4014
3.6 Has the entity 'transferred' the asset?	4014
3.6.1 Transfers of contractual rights to receive cash flows	4014
3.6.1.A Meaning of 'transfers the contractual rights to receive the cash flows'	4015
3.6.1.B Transfers subject to conditions	4016

3.6.2	Retention of rights to receive cash flows subject to obligation to pay over to others (pass-through arrangement)	4017
3.6.2.A	Recourse to originator	4018
3.6.2.B	Short-term loan facilities	4018
3.6.2.C	Insurance protection	4019
3.6.2.D	Treatment of collection proceeds	4019
3.6.2.E	Transfers of non-optional derivatives along with a group of financial assets	4020
3.6.2.F	'Empty' subsidiaries or SPEs	4020
3.7	Has the entity transferred or retained substantially all the risks and rewards of ownership?	4021
3.7.1	Transfers resulting in transfer of substantially all risks and rewards	4021
3.7.2	Transfers resulting in retention of substantially all risks and rewards	4022
3.7.3	Transfers resulting in neither transfer nor retention of substantially all risks and rewards	4022
3.7.4	Evaluating the extent to which risks and rewards are transferred - practical example	4022
3.7.5	Transfer of risks on a cumulative basis	4026
3.8	Has the entity retained control of the asset?	4027
3.8.1	Transferee's 'practical ability' to sell the asset	4027
4	Practical application of the derecognition criteria	4028
4.1	Repurchase agreements ('repos') and securities lending	4028
4.1.1	Agreements to return the same asset	4028
4.1.1.A	Transferee's right to pledge	4028
4.1.2	Agreements with right to return the same or substantially the same asset	4028
4.1.3	Agreements with right of substitution	4028
4.1.4	Net cash-settled forward repurchase	4029
4.1.5	Agreement to repurchase at fair value	4029
4.1.6	Right of first refusal to repurchase at fair value	4029
4.1.7	Wash sale	4029
4.2	Transfers subject to put and call options	4029
4.2.1	Deeply in the money put and call options	4030
4.2.2	Deeply out of the money put and call options	4030
4.2.3	Options that are neither deeply out of the money nor deeply in the money	4030
4.2.3.A	Assets readily obtainable in the market	4030
4.2.3.B	Assets not readily obtainable in the market	4030
4.2.4	Option to put or call at fair value	4031
4.2.5	Net cash-settled options	4031
4.2.6	Removal of accounts provision	4031
4.2.7	Clean-up call options	4031
4.2.8	Same (or nearly the same) price put and call options	4031
4.2.9	Changes in probability of exercise of options after initial transfer of asset	4031
4.3	Subordinated retained interests and credit guarantees	4033
4.4	Transfers involving swaps	4033
4.4.1	Total return swaps	4033
4.4.2	Interest rate swaps	4033
4.5	Factoring of trade receivables	4034

5	Accounting treatment	4035
5.1	Transfers that qualify for derecognition	4035
5.1.1	Transferred asset part of a larger asset	4036
5.1.2	Servicing assets and liabilities	4037
5.2	Transfers that do not qualify for derecognition through retention of risks and rewards	4039
5.3	Transfers with continuing involvement - summary	4043
5.3.1	Guarantees	4043
5.3.2	Options	4044
5.3.3	Associated liability	4044
5.3.4	Subsequent measurement of assets and liabilities	4044
5.3.5	Continuing involvement in part only of a larger asset	4044
5.4	Transfers with continuing involvement - accounting examples	4045
5.4.1	Transfers of assets measured at amortised cost with guarantees	4045
5.4.2	Transfers of assets measured at amortised cost with an option	4048
5.4.3	Transfers of assets measured at fair value with an option	4049
5.4.3.A	Transferor's call option	4049
5.4.3.B	Transferee's put option	4051
5.4.3.C	'Collar' put and call options	4052
5.4.4	Continuing involvement in part only of a financial asset	4054
5.5	Miscellaneous provisions	4056
5.5.1	Offset	4056
5.5.2	Collateral	4056
5.5.3	Rights or obligations over transferred assets that continue to be recognised	4056
5.6	Reassessing derecognition	4057
5.6.1	Reassessment of consolidation of subsidiaries and SPEs	4057
6	Derecognition - financial liabilities	4058
6.1	Extinguishment of debt	4058
6.1.1	What constitutes 'part' of a liability?	4060
6.1.2	Legal release by creditor	4060
6.1.3	'In-substance defeasance' arrangements	4061
6.1.4	Extinguishment in exchange for transfer of assets not meeting the derecognition criteria	4061
6.1.5	Debt repurchased by the issuer	4061
6.2	Exchange or modification of debt by original lender	4062
6.2.1	When is an exchange or modification of debt 'substantially different'?	4063
6.2.2	Interbank Offered Rate (IBOR) Reform	4064
6.2.3	Loan syndications	4064
6.2.4	Exchange of debt through an intermediary	4064
6.2.5	Costs and fees	4065
6.2.6	Modification gains and losses	4066
6.2.7	Illustrative examples	4067
6.2.8	Settlement of financial liability with issue of new equity instrument	4069

6.3	Gains and losses on extinguishment of debt	4069
6.4	Derivatives that can be financial assets or financial liabilities	4070
6.5	Supply-chain finance	4070
7	CUSIP 'netting'	4071
8	Client money	4072
9	Current and future developments	4073
9.1	Modification of financial assets and liabilities	4073

Appendix B - Defined terms		4075

Overview

This chapter deals with the question of when financial instruments must be removed ('derecognised') from financial statements. It provides guidance including illustrations to explain when a financial asset, or a financial liability that has already been recognised in financial statements must no longer be included.

In deciding whether derecognition of financial assets is required, multiple factors need to be considered, including whether the contractual rights to the financial instrument have been transferred, whether the risks and rewards are retained and the extent to which the financial asset has been modified.

The question of derecognition goes further than just considering on balance sheet financial assets and liabilities and it encroaches on what is commonly referred to as 'off-balance sheet' finance. The outcome of the derecognition analysis can affect whether certain transactions are presented as financing (e.g., where funding is received and the related asset is not derecognised) or an off-balance sheet transaction (e.g., where sales proceeds are received, and the financial asset is derecognised).

In May 2024, the IASB amended IFRS 9 to provide additional guidance and clarity on specific matters following completion of the IFRS 9 post-implementation review (PIR) for Classification and Measurement ("the Amendments"). The Amendments are applicable for annual periods beginning on or after 1 January 2026. Entities are permitted to early adopt all of the amendments, or only the amendments that relate to the classification of financial assets with the related disclosure in IFRS 7 *Financial Instruments: Disclosures* (refer to Chapter 50) before applying the other amendments later [IFRS 9.7.1.13].

The Amendments are applied retrospectively, but an entity is not required to restate prior periods. Restatement of prior periods is permitted if, and only if, it is possible to do so without the use of hindsight. If an entity does not restate prior periods, it shall recognise the effect of initially applying these amendments as an adjustment to the opening balance of financial assets and financial liabilities and the cumulative effect, if any, as an adjustment to the opening balance of retained earnings (or other component of equity, as appropriate) at the date of initial application. [IFRS 9.7.2.48].

The Amendments relating to derecognition of financial assets are covered in section 3.5 and to financial liabilities in section 6.1. These sections use separate headings to specify the requirements applicable under these Amendments for periods beginning on or after 1 January 2026, as well as those applying before 1 January 2026.

FASB differences

Differences between IFRS accounting standards and the US GAAP guidance on this topic are not addressed in this chapter as the standards are not converged. Therefore, differences between IFRS accounting standards and US GAAP may exist that are not discussed in this chapter.

What you need to know

- To help the assessment of whether financial assets are derecognised, IFRS 9 *Financial Instruments* includes a decision tree that lays out the individual steps and the order in which they have to be considered. Any derecognition assessment for a financial asset should refer to this flowchart as a starting point.
- Certain types of structures and transactions, for example securitisations, result in an entity retaining ownership of a group of financial assets whilst assuming an obligation to pass the contractual cash flows received on to other parties. These require application of what are often referred to as the 'pass-through' rules to determine whether the assets have actually been transferred.
- Combinations of transactions entered into with the same counterparty at the same time as a transfer of a financial asset, such as a sale of a security with a total return swap, must be considered together when assessing whether the security has to be derecognised.
- For financial liabilities, the derecognition analysis considers whether the contractual obligations have been extinguished or expired.
- When a financial instrument is modified or restructured, it will be necessary to assess whether this represents the expiry of the original rights and obligations and hence whether the original instrument is derecognised to be replaced by a new instrument measured at fair value. This may apply for example if the terms of a loan are amended to extend the maturity and/or change the coupon.
- For a borrower, IFRS 9 contains more specific guidance for determining whether a modification results in derecognition of a financial liability than it does for a lender's financial asset, including the notion of a 10% test.

1 Interaction with other IFRS accounting standards

Under IFRS, many definitions relating to financial instruments are in IAS 32 *Financial Instruments: Presentation* while derecognition of financial assets and financial liabilities is currently addressed in IFRS 9. The definition of fair value, as defined in IFRS 13 *Fair Value Measurement* is also relevant for the application of the derecognition provisions in practice. This is discussed further in Chapter 15.

The provisions of IFRS 10 *Consolidated Financial Statements* are also very relevant to certain aspects of the derecognition of financial assets and financial liabilities. IFRS 10 is discussed in Chapter 7, but it is also referred to at various points below.

Whilst IFRS 9 introduced major changes to the way in which financial instruments were reflected in financial statements, its requirements relating to derecognition were substantially the same as those in IAS 39 *Financial Instruments: Recognition and Measurement*. Accordingly, consideration by the IFRS IC of the application of these parts of IAS 39 continue to be relevant under IFRS 9. Therefore, references to such discussions are included in this chapter as if the IFRS IC was considering IFRS 9.

Disclosure requirements in respect of transfers of financial assets are included in IFRS 7 *Financial Instruments: Disclosures* and these are discussed in Chapter 50.

2 Definitions and scope

2.1 Definitions

The following definitions abbreviated from IAS 32, IFRS 9 and IFRS 13 are generally relevant to the discussion in this chapter.

Extract from IFRS standards - Definitions

derecognition	The removal of a previously recognised financial asset or financial liability from an entity's statement of financial position. <i>[IFRS 9 Appendix A].</i>
derivative	<p>A financial instrument or other contract within the scope of this Standard with all three of the following characteristics.</p> <ul style="list-style-type: none"> (a) its value changes in response to the change in a specified interest rate, financial instrument price, commodity price, foreign exchange rate, index of prices or rates, credit rating or credit index, or other variable, provided in the case of a non-financial variable that the variable is not specific to a party to the contract (sometimes called the 'underlying'). (b) it requires no initial net investment or an initial net investment that is smaller than would be required for other types of contracts that would be expected to have a similar response to changes in market factors. (c) it is settled at a future date. <i>[IFRS 9 Appendix A].</i>
fair value	The price that would be received to sell an asset or paid to transfer a liability in an orderly transaction between market participants at the measurement date. <i>[IFRS 13 Appendix A].</i>
financial asset	<p>A financial asset is any asset that is:</p> <ul style="list-style-type: none"> (a) cash; (b) an equity instrument of another entity; (c) a contractual right: <ul style="list-style-type: none"> (i) to receive cash or another financial asset from another entity; or (ii) to exchange financial assets or financial liabilities with another entity under conditions that are potentially favourable to the entity; or (d) a contract that will or may be settled in the entity's own equity instruments and is: <ul style="list-style-type: none"> (i) a non-derivative for which the entity is or may be obliged to receive a variable number of the entity's own equity instruments; or (ii) a derivative that will or may be settled other than by the exchange of a fixed amount of cash or another financial asset for a fixed number of the entity's own equity instruments. <p>For this purpose the entity's own equity instruments do not include puttable financial instruments classified as equity instruments in accordance with paragraphs 16A and 16B, instruments that impose on the entity an obligation to deliver to another party a pro rata share of the net assets of the entity only on liquidation and are classified as equity instruments in accordance with paragraphs 16C and 16D, or instruments that are contracts for the future receipt or delivery of the entity's own equity instruments. <i>[IAS 32.11].</i></p>
financial instrument	A financial instrument is any contract that gives rise to a financial asset of one entity and a financial liability or equity instrument of another entity. <i>[IAS 32.11].</i>

financial liability

A *financial liability* is any liability that is:

- (a) a contractual obligation:
 - (i) to deliver cash or another financial asset to another entity; or
 - (ii) to exchange financial assets or financial liabilities with another entity under conditions that are potentially unfavourable to the entity; or
- (b) a contract that will or may be settled in the entity's own equity instruments and is:
 - (i) a non-derivative for which the entity is or may be obliged to deliver a variable number of the entity's own equity instruments; or
 - (ii) a derivative that will or may be settled other than by the exchange of a fixed amount of cash or another financial asset for a fixed number of the entity's own equity instruments. For this purpose, rights, options or warrants to acquire a fixed number of the entity's own equity instruments for a fixed amount of any currency are equity instruments if the entity offers the rights, options or warrants pro rata to all of its existing owners of the same class of its own non-derivative equity instruments. Also, for these purposes the entity's own equity instruments do not include puttable financial instruments that are classified as equity instruments in accordance with paragraphs 16A and 16B, instruments that impose on the entity an obligation to deliver to another party a pro rata share of the net assets of the entity only on liquidation and are classified as equity instruments in accordance with paragraphs 16C and 16D, or instruments that are contracts for the future receipt or delivery of the entity's own equity instruments.

As an exception, an instrument that meets the definition of a financial liability is classified as an equity instrument if it has all the features and meets the conditions in paragraphs 16A and 16B or paragraphs 16C and 16D. [IAS 32.11].

modification gain or loss

The amount arising from adjusting the **gross carrying amount of a financial asset** to reflect the renegotiated or modified contractual cash flows. The entity recalculates the gross carrying amount of a financial asset as the present value of the estimated future cash payments or receipts through the expected life of the renegotiated or modified financial asset that are discounted at the financial asset's original **effective interest rate** (or the original **credit-adjusted effective interest rate** for **purchased or originated credit-impaired financial assets**) or, when applicable, the revised **effective interest rate** calculated in accordance with paragraph 6.5.10. When estimating the expected cash flows of a financial asset, an entity shall consider all contractual terms of the financial asset (for example, prepayment, call and similar options) but shall not consider the **expected credit losses**, unless the financial asset is a **purchased or originated credit-impaired financial asset**, in which case an entity shall also consider the initial expected credit losses that were considered when calculating the original **credit-adjusted effective interest rate**. [IFRS 9 Appendix A].

transaction costs

Incremental costs that are directly attributable to the acquisition, issue or disposal of a financial asset or financial liability (see paragraph B5.4.8). An incremental cost is one that would not have been incurred if the entity had not acquired, issued or disposed of the financial instrument. [IFRS 9 Appendix A].

2.2 Scope

The scope for application of IFRS 9 to financial instruments is detailed in Chapter 41. The derecognition requirements within IFRS 9 apply more widely in that they also specifically apply to the following items which are normally dealt with outside of that Standard:

- Finance lease receivables (i.e., net investments in finance leases) and operating lease receivables recognised by a lessor [IFRS 9.2.1(b)(i)]
 - Lease liabilities recognised by a lessee [IFRS 9.2.1(b)(ii)]
- And
- Loan commitments [IFRS 9.2.1(g)]

In July 2024, the IASB published a narrow-scope amendment regarding the derecognition of lease liabilities recognised by a lessee. In the amendment, they clarified that, when a lessee has determined that a lease liability has been extinguished in accordance with IFRS 9, the lessee is required to apply paragraph 3.3.3 of IFRS 9 and recognise any resulting gain or loss in profit or loss. Further information regarding these amendments is discussed at section 6.3 below.

In the context of contracts with customers that fall into the scope of IFRS 15 *Revenue from Contracts with Customers*, when an entity satisfies a performance obligation by transferring a promised good or service, the entity has earned a right to consideration from the customer. [IFRS 15.105]. If the right to consideration is conditional, it is a contract asset (for example, when an entity must first satisfy another performance obligation in the contract before it is entitled to payment from the customer). On the other hand, if an entity has an unconditional right to receive consideration from the customer (i.e., only the passage of time is required before payment is due), the entity has a receivable. While IFRS 9, including its derecognition requirements, applies to receivables, [IFRS 9.2.1(j), IFRS 15.108], only the impairment requirements of IFRS 9 apply to contract assets. [IFRS 15.107].

How we see it

In theory, entities could also apply the derecognition guidance in IFRS 9 by analogy to contract assets. However, in practice, we believe that it is unlikely that arrangements involving contract assets would meet the requirements for derecognition in IFRS 9, particularly if they are still conditional on the entity's future performance.

3 Derecognition - financial assets

3.1 Background

The requirements of IFRS 9 for derecognition of financial assets are primarily designed to deal with the accounting challenges posed by various types of off-balance sheet finance. As a result, the real focus of many of the rules for derecognition of assets is in fact the recognition of liabilities. The starting point for most of the transactions discussed below is that the reporting entity receives cash or other consideration in return for a transfer or 'sale' of all or part of a financial asset. This raises the question of whether such consideration is to be treated as sales proceeds or as a liability. IFRS 9 effectively answers that question by determining whether the financial asset to which the consideration relates must be derecognised (the consideration is treated as sales proceeds and there is a gain or loss on disposal) or continues to be recognised while the consideration is treated as a liability.

This underlying objective of the derecognition criteria helps to explain why IFRS 9 considers not only the economic position of the entity at the reporting date, but also prior transactions which gave rise to that position and the reporting entity's motives in undertaking them. For example, if, at a reporting date, an entity has two identical forward contracts for the purchase of a financial asset, the accounting treatment of the contracts may vary significantly if one contract relates to the purchase of an asset previously owned by the entity and the other does not.

This is because the derecognition rules of IFRS 9 are based on the premise that, if a transfer of an asset leaves the transferor's economic exposure to the transferred asset much as if the transfer had never taken place, the financial statements must represent that the transferor still holds the asset. Thus, if an entity sells 'say' a listed bond subject to a forward contract to repurchase the bond from the buyer at a fixed price, IFRS 9 argues that the entity is exposed to the risks and rewards of that bond as if it had never sold it, but has simply borrowed an amount equivalent to the original sales proceeds secured on the bond. IFRS 9 therefore concludes that the bond must not be removed from the statement of financial position and the sale proceeds must be accounted for as a liability (in effect the obligation to repurchase the bond under the forward contract - see section 4.1 below).

By contrast, if the entity were to enter into a second identical forward contract over another bond (i.e., one not previously owned by the entity), IFRS 9 would simply require it to be accounted for as a derivative at fair value (see Chapter 42). This might seem a rather counter-intuitive outcome of a framework that purports to report economically equivalent transactions in a consistent and objective manner. However, the IASB would argue that the two transactions are not economically equivalent; they are distinguished by the fact that, on entering into the forward contract over the originally owned asset, the entity received a separate cash inflow (i.e., the 'sale' proceeds from the counterparty), whereas, on entering into the second contract, it did not. This reinforces the point that the real focus of IFRS 9 is to determine the appropriate accounting treatment for that cash inflow and not that of the previously owned bond *per se*.

3.2 Decision tree

The provisions of IFRS 9 concerning the derecognition of financial assets are complex but are summarised in Figure 3-1 below. [IFRS 9.B3.2.1]. It may be helpful to refer to this while reading the discussion that follows.

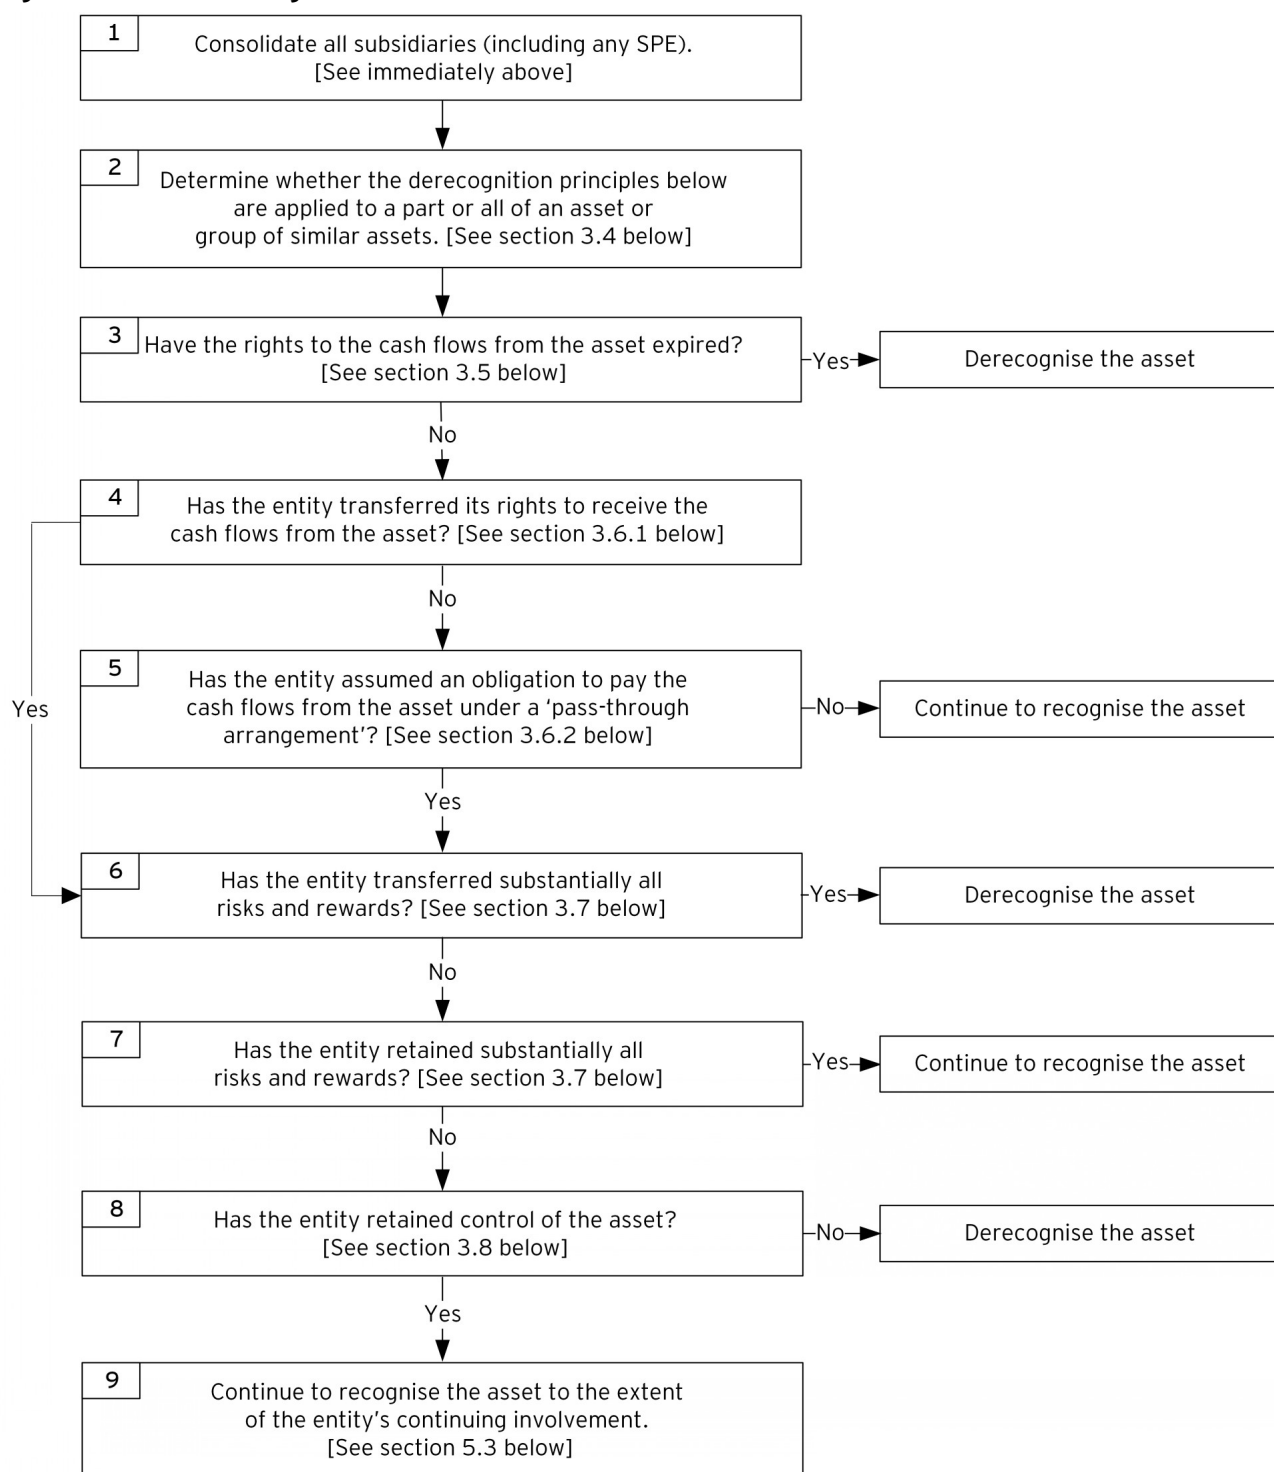

It will be seen that the process presupposes that the reporting entity has correctly consolidated all its subsidiaries in accordance with IFRS 10, including any entities identified as consolidated structured entities, often called special purpose entities (SPEs) (see Chapter 7 and section 3.3 below).

Under IFRS, a vehicle (or a structured entity) that, though not meeting a traditional definition of a subsidiary based on ownership of equity, is still controlled by the entity is often referred to as a (consolidated) SPE. IFRS 10 requires a reporting entity to consolidate another entity, including an SPE, when the reporting entity is exposed, or has rights, to variable returns from its involvement with the investee entity and has the ability to affect those returns through its power over the investee entity (see section 3.3 below).

It is clearly highly significant from an accounting perspective that an entity to which a financial asset or liability is transferred is a subsidiary or a consolidated SPE of the transferor. A financial asset (or financial liability) transferred from an entity to its subsidiary or consolidated SPE (on whatever terms) will continue to be recognised in the entity's consolidated financial statements through the normal consolidation procedures set out in IFRS 10. Thus, the requirements discussed in sections 3.4 to 3.8 below are irrelevant to the treatment, in an entity's consolidated financial statements, of any transfer of a financial asset by the entity to a subsidiary or consolidated SPE. Requiring consolidation of subsidiaries and certain SPEs means that the same derecognition analysis applies whether the entity transfers the financial assets directly to a third-party investor, or to a subsidiary or consolidated SPE that carries out the transfer.

However, the criteria may be relevant to any onward transfer by the subsidiary or consolidated SPE, and to the transferor's separate financial statements, if prepared (see Chapter 9).

Figure 3-1: Derecognition flowchart

[IFRS 9.B3.2.1].

The subsequent steps towards determining whether derecognition is appropriate are discussed below. Some examples of how these criteria might be applied to some common transactions in financial assets are given in section 4 below. The accounting consequences of the derecognition of a financial asset are discussed in section 5 below.

3.2.1 Importance of applying tests in sequence

The derecognition rules in IFRS 9 are based on several different accounting concepts, in particular a 'risks and rewards' model and a 'control' model, which may lead to opposite conclusions.

For example, an entity (A) might have a portfolio of listed shares for which there is a deep liquid market. It might enter into a contract with a third-party counterparty (B) on the following terms. A sells the portfolio to B for CU10 million, agreeing to repurchase it in two years' time for CU10 million plus interest at market rates on CU10 million less dividends on the shares.

The nature of the portfolio is such that B is able to sell it to third parties (since it will easily be able to reacquire the necessary shares to deliver back to A under the repurchase agreement). This indicates that B has control over the portfolio and therefore, since the same asset cannot be controlled by more than one party, that A does not. Thus, under a 'control' model of derecognition, A would derecognise the portfolio.

However, the nature of the repurchase agreement is also such that A is exposed to all the economic risks and rewards of the portfolio as if it had never been sold to B (since the repurchase price effectively returns to A all dividends paid on the portfolio, and all movements in its market value, during its period of ownership by B). Thus, under a 'risks and rewards' model of derecognition, A would continue to recognise the portfolio.

IFRS 9 seeks to avoid the potential conflict between those accounting models by the practically effective requirement to consider them in the strict sequence in Figure 3-1 in section 3.2 above - i.e., the 'risks and rewards' model first and the 'control' model second. Thus, as will be seen from the discussion below (particularly in sections 4 and 5 below) if A transfers an asset to B on terms that B is free to sell the asset:

- If A retains substantially all the risks and rewards of the asset (i.e., the answer to Box 7 in Figure 3-1 is 'Yes'), B's right to sell is irrelevant and the asset continues to be recognised by A.

But

- If A has neither transferred nor retained substantially all the risks and rewards of the asset (i.e., the answer to Box 7 in Figure 3-1 is 'No'), B's right to sell is highly relevant, indicating a loss of control over the asset by A (i.e., the answer to Box 8 in Figure 3-1 is 'No'), such that A derecognises the asset.

In other words, depending on the reporting entity's position in the decision tree in section 3.2 above, the fact that B has the right to sell the asset is either irrelevant or leads directly to derecognition of the asset by A. It is therefore crucial that the various asset derecognition tests in IFRS 9 are applied in the required order.

3.3 Consolidation of all subsidiaries (including any SPEs)

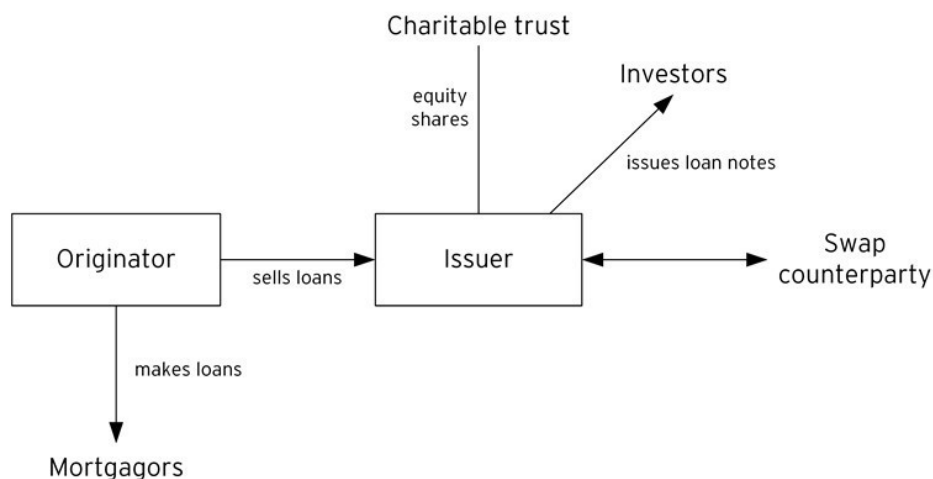

The discussion in this section refers to Box 1 in Figure 3-1 in section 3.2 above.

The first step of the decision tree, at least when preparing consolidating financial statements, is to ensure all subsidiaries are consolidated. This is because many transactions that could result in derecognition involve transactions with another member of the group, but these will be eliminated on consolidation. The analysis can be different for the standalone financial statements, in which case the entity would follow the remaining steps even where the transactions are with another group member.

This first step is particularly important in the context of securitisations, which is a process whereby finance can be raised from external investors by enabling them to invest indirectly in parcels of specific financial assets. The first main type of assets to be securitised was domestic mortgage loans, but the technique is regularly extended to other assets, such as credit card receivables, other consumer loans, or lease receivables. Securitisations are a complex area of financial reporting beyond the scope of a general text such as this to discuss in detail. However, it may assist in the understanding of the IASB's thinking to consider a 'generic' example of such a transaction.

A typical securitisation transaction involving a portfolio of mortgage loans would operate as follows. The entity which has initially advanced the loans in question (the 'originator') will sell them to another entity, an SPE, set up for that purpose (the 'issuer'). The share capital of the issuer, which will be small, will often be owned by a trustee on behalf of a charitable trust. The issuer will finance its purchase of these loans by issuing multiple types of loan notes, that have a subordination ranking specifying the order in which any cash flows generated by the mortgage loans are allocated to individual notes. The interest terms on the aggregate of these notes need to be related to the rate of interest receivable on the mortgages and to achieve this the issuer may need to enter into derivative instruments such as interest rate swaps. Any such swap counterparty may be the originator or a third party. The originator will continue to administer the loans as before, for which it will receive a service fee from the issuer.

The structure might therefore be as shown in this diagram:

Potential investors in the mortgage-backed loan notes will want to be assured that their investment is relatively risk free and the issue will normally be supported by obtaining a high rating from a credit rating agency. This may be achieved by using a range of credit enhancement techniques which will add to the security already inherent in the quality of the mortgage portfolio. Such techniques can include the following:

- Limited recourse to the originator in the event that the income from the mortgages falls short of the interest payable to the investors under the loan notes and other expenses. This may be made available in a number of ways: for example, by the provision of subordinated loan finance from the originator to the issuer; by the deferral of part of the consideration for the sale of the mortgages; or by the provision of a guarantee (see section 3.6.2.A below).
- The provision of short-term loan facilities to meet temporary shortfalls as a result of slow payments of mortgage interest (see section 3.6.2.B below).

Or

- Insurance against default on the mortgages (see section 3.6.2.C below).

The overall effect of the arrangement is that outside investors have been brought in to finance a particular portion of the originator's activities. These investors have first call on the income from the mortgages which back their investment. The originator generally retains the residual interest in the differential between the rates paid on the notes and earned on the mortgages, net of expenses. Generally, this profit element is extracted by adjustments to the service fee. It has thus limited its upside interest in the mortgages, while its remaining downside risk on the whole arrangement will depend on the extent to which it has assumed obligations under the credit enhancement measures.

Determining whether issuer is a consolidated or unconsolidated SPE can be a highly judgemental area which requires careful analysis. For more guidance refer to Chapter 7.

If the issuer is consolidated by the originator, then all intragroup transactions are eliminated and only the externally held notes will be accounted for. In most cases, the originator will not derecognise the securitised assets, but instead recognise the loan notes as financial liabilities, unless the issuer is able to demonstrate that it operates as a qualifying pass-through arrangement. For more guidance on pass-through arrangements refer to section 3.6.2.

If the issuer is not consolidated by the originator, then the originator should consider the transactions with the issuer using remaining steps on the decision tree. The application of IFRS 9 to securitisations is dealt with further in section 3.6.1 and section 3.6.2.

For a general discussion on the initial recognition and impairment considerations of the financial assets and liabilities for the transferee in a securitisation structure involving an SPE, we refer to Chapter 47.

3.4 Determination of whether the derecognition principles apply to a part or all of an asset or groups of assets

The discussion in this section relates to Box 2 in Figure 3-1 in section 3.2 above.

IFRS 9 requires an entity, before evaluating whether, and to what extent, derecognition is appropriate, to determine whether the provisions discussed in this chapter are applied to the whole, or a part only, of a financial asset (or the whole or, a part only, of a group of similar financial assets).

It is important to remember throughout the discussion below that these are criteria for determining at what level the derecognition rules are applied, not for determining whether the conditions in those rules have been satisfied.

Extract from IFRS 9

3.2.2 Before evaluating whether, and to what extent, *derecognition* is appropriate under paragraphs 3.2.3-3.2.9, an entity determines whether those paragraphs should be applied to a part of a financial asset (or a part of a group of similar financial assets) or a financial asset (or a group of similar financial assets) in its entirety, as follows.

- (a) Paragraphs 3.2.3-3.2.9 are applied to a part of a financial asset (or a part of a group of similar financial assets) if, and only if, the part being considered for derecognition meets one of the following three conditions.
 - (i) The part comprises only specifically identified cash flows from a financial asset (or a group of similar financial assets). For example, when an entity enters into an interest rate strip whereby the counterparty obtains the right to the interest cash flows, but not the principal cash flows from a debt instrument, paragraphs 3.2.3-3.2.9 are applied to the interest cash flows.
 - (ii) The part comprises only a fully proportionate (pro rata) share of the cash flows from a financial asset (or a group of similar financial assets). For example, when an entity enters into an arrangement whereby the counterparty obtains the rights to a 90 per cent share of all cash flows of a debt instrument, paragraphs 3.2.3-3.2.9 are applied to 90 per cent of those cash flows. If there is more than one counterparty, each counterparty is not required to have a proportionate share of the cash flows provided that the transferring entity has a fully proportionate share.
 - (iii) The part comprises only a fully proportionate (pro rata) share of specifically identified cash flows from a financial asset (or a group of similar financial assets). For example, when an entity enters into an arrangement whereby the counterparty obtains the rights to a 90 per cent share of interest cash flows from a financial asset, paragraphs 3.2.3-3.2.9 are applied to 90 per cent of those interest cash flows. If there is more than one counterparty, each counterparty is not required to have a proportionate share of the specifically identified cash flows provided that the transferring entity has a fully proportionate share.
- (b) In all other cases, paragraphs 3.2.3-3.2.9 are applied to the financial asset in its entirety (or to the group of similar financial assets in their entirety). For example, when an entity transfers (i) the rights to the first or the last 90 per cent of cash collections from a financial asset (or a group of financial assets), or (ii) the rights to 90 per cent of the cash flows from a group of receivables, but provides a guarantee to compensate the buyer for any credit losses up to 8 per cent of the principal amount of the receivables, paragraphs 3.2.3-3.2.9 are applied to the financial asset (or a group of similar financial assets) in its entirety.

In paragraphs 3.2.3-3.2.12, the term 'financial asset' refers to either a part of a financial asset (or a part of a group of similar financial assets) as identified in (a) above or, otherwise, a financial asset (or a group of similar financial assets) in its entirety.

The various examples provided above illustrate that the tests in (a)(i) to (a)(iii) are to be applied very strictly. It is essential that the entity transfers 100%, or a lower fixed proportion, of a definable cash flow. In the arrangement in IFRS 9.3.2.2(b), the transferor provides a guarantee the effect of which is that the transferor may have to return some part of the consideration it has already received. This has the effect that the derecognition provisions must be applied to the asset in its entirety and not just to the proportion of cash flows transferred. If the guarantee had not been given, the arrangement would have satisfied condition (a) above, and the derecognition provisions would have been applied only to the 90% of cash flows transferred. [IFRS 9.3.2.2]. The application of these provisions has been further explained in section 5.

The criteria in IFRS 9.3.2.2, must be applied to the whole, or a part only, of a financial asset or the whole, or a part only, of a group of similar financial assets. This raises the question of what comprises a 'group of similar financial assets' - an issue that has been discussed by the IFRS IC and the IASB but without them being able to reach any satisfactory conclusions (see section 3.4.2 below).

In the derecognition provisions in IFRS 9, as well as the discussion in sections 3 to 5 of this chapter, the term 'financial asset' is used to refer to either the whole, or a part, of a financial asset (or the whole or a part of a group of similar financial assets). [IFRS 9.3.2.2]. It is therefore important to remember throughout the following discussion that a reference to an asset being derecognised 'in its entirety' does not necessarily mean that 100% of the asset is derecognised. It may mean, for example, that there has been full derecognition of, say, 80% of the asset to which the derecognition rules have applied separately (in accordance with the criteria above).

3.4.1 Transfer of asset (or part of asset) for only part of its life

The examples given in IFRS 9 implicitly appear to have in mind the transfer of cash flows from the date of transfer for the remainder of the life of an instrument. This raises the question of the appropriate accounting treatment where (for example) an entity with a loan receivable repayable in 10 years' time enters into a transaction whereby all the interest flows for the next 5 years only (or those for years 6 to 10) are transferred to a third party. There is no reason why such a transaction could not be considered for partial derecognition.

3.4.2 Derecognition of groups of similar financial assets

As described above, the derecognition provisions of IFRS 9 apply to the whole, or a part only, of a financial asset or a group, or a part of a group, of similar financial assets. However, transfers of financial assets, such as debt factoring or securitisations (see section 3.6 below), typically involve the transfer of a group of assets (and possibly similar liabilities) comprising:

- The non-derivative financial assets (i.e., the trade receivables or securitised assets) that are the main focus of the transaction.
 - Financial instruments taken out by the transferor in order to mitigate the risk of those financial assets. These arrangements may either have already been in place for some time, or they may have been entered into to facilitate the transfer.
- And
- Non-derivative financial guarantee contracts that are transferred with the assets. These are not always recognised separately as financial assets, e.g., mortgage indemnity guarantees which compensate the lending bank if the borrower defaults and there is a deficit when the secured property is sold. Such guarantees may be transferred together with the mortgage assets to which they relate.

Financial instruments transferred with the 'main' assets also typically include derivatives such as interest rate and currency swaps. The entity may have entered into such arrangements in order to swap floating rate mortgages to fixed rate, or to change the currency of cash flows receivable from financial assets to match the currency of the borrowings, e.g., sterling into euros.

Both the IFRS IC and the IASB have considered whether the reference to transfers of 'similar' assets in IFRS 9 is intended to require:

- A single derecognition test for the whole 'package' of transferred non-derivative assets, and any associated financial instruments, as a whole
- Or
- Individual derecognition tests for each type of instrument (e.g., loan, interest rate swap, guarantee or credit insurance) transferred

The IASB and IFRS IC did not succeed in clarifying the meaning of 'similar assets'. The IFRS IC came to a tentative decision but passed the matter to the IASB, together with some related derecognition issues, in particular, the types of transaction that are required to be treated as 'pass through' and the effect of conditions attached to the assets that have been transferred (discussed in section 3.6.2 below). In November 2006 the IFRS IC issued a tentative decision not to provide formal guidance, based on the views publicly expressed by the IASB in the *IASB Update* for September 2006. The IFRS IC's decision not to proceed was withdrawn in January 2007 on the basis of comment letters received by the IFRS IC that demonstrated that the IASB's 'clarification' was, in fact, unworkable and further guidance was required after all. The IFRS IC announced this as follows:

"In November 2006, the IFRIC published a tentative agenda decision not to provide guidance on a number of issues relating to the derecognition of financial assets. After considering the comment letters received on the tentative agenda decision, the IFRIC concluded that additional guidance is required in this area. The IFRIC therefore decided to withdraw the tentative agenda decision [not to provide further guidance] and add a project on derecognition to its agenda. The IFRIC noted that any Interpretation in this area must have a tightly defined and limited scope, and directed the staff to carry out additional research to establish the questions that such an Interpretation should address."¹

The next section describes the IFRS IC's and IASB's attempts to establish the meaning of 'similar', which demonstrated the absence of a clear principle. There is bound to be diversity in practice in the light of the failure to provide an interpretation, so it is most important that entities establish an accounting policy that they apply consistently to the derecognition of groups of similar financial assets.

3.4.2.A The IASB's view and the IFRS IC's tentative conclusions

Although the IFRS IC initially tended to the view that the IASB intended a single test to be undertaken,² the IASB itself indicated that derivatives transferred together with non-derivative financial assets were not 'similar' to non-derivative financial assets for the purposes of what is now IFRS 9.3.2.2. Therefore, an entity would apply the derecognition tests in IFRS 9 to non-derivative financial assets (or groups of similar non-derivative financial assets) and derivative financial assets (or groups of similar derivative financial assets) separately, even if they were transferred at the same time.³ The IASB also indicated that, in order to qualify for derecognition, transferred derivatives that could be assets or liabilities (such as interest rate swaps) would have to meet both the financial asset and the financial liability derecognition tests⁴ - see the further discussion of this issue in section 6.4 below. Whilst the IASB's published decision referred only to derivatives transferred with the main non-derivative assets, observers of the relevant meeting reported that the IASB also took the view that the derecognition tests must also be applied separately to other financial assets, such as guarantees and credit insurance, transferred with the main assets.

This can have practical effects on many securitisations as currently structured (see section 3.3 above). The interpretation can make it easier to derecognise certain items (particularly non-derivative assets). This is because many derivatives themselves might not meet the appropriate derecognition criteria at all and would continue to be recognised. Also, a transaction might achieve a transfer of substantially all the risks and rewards (see Box 6 in Figure 3-1 in section 3.2 above, and section 3.7 below) of a transferred asset considered separately from any associated derivatives or guarantees, but not if the asset and the associated derivatives or guarantees are considered as a whole. However, the interpretation can well result in far more arrangements falling into the category of 'continuing involvement', where the entity has neither retained nor disposed of substantially all of the risks and rewards of ownership.

Suppose that an entity transfers a fixed rate loan subject to prepayment risk and a credit guarantee, but retains prepayment risk through an amortising interest rate swap, linked to the principal amount of the transferred loan, with the transferee. On the view that the loan and guarantee should be considered for derecognition as a whole, there was no real credit risk prior to the transfer because of the guarantee. The entity was exposed to prepayment risk and the risk of failure by the counterparty to the guarantee. On the assumption that the latter risk could be considered negligible, the only real risk was prepayment risk. Thus, on the view that the loan and guarantee should be considered for derecognition as a whole, they would probably not be derecognised because the entity would retain the only substantial risk (prepayment risk) to which it was exposed before the transfer - i.e., the transaction would fail the test of transferring substantially all risks and rewards in Box 6 in Figure 3-1 in section 3.2 above.

1 [IFRIC Update](#), January 2007, available on the IFRS Foundation's website.

2 [IFRIC Update](#), May 2006, available on the IFRS Foundation's website.

3 [IASB Update](#), September 2006, available on the IFRS Foundation's website.

4 [IASB Update](#), September 2006, available on the IFRS Foundation's website.

Following the IASB's decision, the implication is that the derecognition criteria would be applied separately to the loan and the guarantee. Considered individually, the loan gives rise to prepayment risk and credit risk. On this analysis, the transfer would leave the entity with only one of the two substantial risks (i.e., prepayment risk, but not credit risk) that it bore previously. This could lead to the conclusion that the entity had neither transferred nor retained substantially all the risks of the loan, and that the loan would therefore be recognised only to the extent of the entity's continuing involvement (in this example, the interest rate swap) - see Box 9 in Figure 3-1 in section 3.2 above, and section 5.3 below. (This assumes the transferor had retained control of the asset, which would normally be the case in a transaction such as this.)

3.4.2.B What are 'similar assets'?

There are a number of different derivative and derivative-like instruments that can be transferred together with a non-derivative, including:

- Hedging instruments that are always assets, e.g., interest rate caps
- Hedging instruments that are always liabilities, e.g., written options
- Hedging instruments that may be an asset or liability at any point in time, e.g., interest rate swaps
- Purchased financial guarantee contracts (including those which are considered integral to a loan asset and those which are not) and credit insurance
- Guarantees that are not financial guarantee contracts but are commonly accounted for as derivatives, e.g., mortgage indemnity guarantee contracts

The IASB's interpretation, repeated in its Exposure Draft - *Derecognition*⁵ - would require each of the first three to meet different derecognition treatments. Derivatives that could be financial assets or financial liabilities depending on movements in market value (e.g., interest rate and credit default swaps) would need to meet both the financial asset and financial liability derecognition requirements of IFRS 9 (even though at any one time they would be either an asset or a liability). The derecognition of financial liabilities requires *inter alia* legal release by the counterparty (see section 6 below). In many securitisations there is no cancellation, novation or discharge of swaps 'transferred' to a structured entity, in which case the transferor would not be able to derecognise the instrument. This would raise issues regarding the treatment of the retained swap, as it may not actually expose the entity to risks and rewards any longer. This is discussed further in section 3.6.2.E below.

The interpretation also raises the difficulty of allocating the single cash flow received from the transferee to the various financial instruments transferred. This is discussed further in section 3.6.1 below.

Given the withdrawal of the IFRS IC's 'non-interpretation', there is no underlying principle that would prevent any of the instruments described above being considered 'similar' to the main non-derivative. Therefore, an entity must establish an accounting policy that it applies consistently to all transactions involving the derecognition of assets, not only to those associated with securitisation arrangements. It must bear in mind that a narrow concept of 'similar', in which instruments are treated as separate assets, may make it easier to derecognise some of them but more likely to have to engage with the problems of continuing involvement and more difficult to achieve pass through (see section 3.6.2 below). Regardless of the accounting policy followed, a derivative that involves two-way payments between parties (i.e., the payments are, or could be, from or to either of the parties) shall be derecognised only when both the derecognition criteria for a financial asset and the derecognition criteria for a financial liability are met (see section 6.4 below). In establishing its accounting policy, an entity may wish to differentiate between financial guarantees that are integral to a loan asset and those which are not.

Once an entity has determined what is 'similar', it must consider the derecognition tests (pass through and transfer of risks and rewards) by reference to the same group of 'similar' assets (see section 3.6 below).

⁵ [Exposure Draft - Derecognition](#), April 2009, available on the IFRS Foundation's website.

3.5 Have the contractual rights to cash flows from the asset expired?

The discussion in this section refers to Box 3 in Figure 3-1 in section 3.2 above.

The first step in determining whether derecognition of a financial asset is appropriate is to establish whether the contractual rights to the cash flows from that asset have expired. If they have, the asset is derecognised. Examples might be:

- A loan receivable is repaid
 - The holder of a perpetual debt, whose terms provide for ten annual 'interest' payments that, in effect, provide both interest and a return of capital, receives the final payment of interest
- Or

- A purchased option expires unexercised

If the cash flows from the financial asset have not expired, it is derecognised when, and only when, the entity 'transfers' the asset within the specified meaning of the term in IFRS 9 (see section 3.6 below), and the transfer has the effect that the entity has either:

- Transferred substantially all the risks and rewards of the asset (see section 3.7 below)

Or

- Neither transferred nor retained substantially all the risks and rewards of the asset (see section 3.7 below), and has not retained control of the asset (see section 3.8 below) [IFRS 9.3.2.3]

2024 Amendments applicable for annual periods beginning on or after 1 January 2026 (with early application permitted)

The Amendments introduce new guidance on the date of initial recognition or derecognition which specifies that the entity derecognises a financial liability on the settlement date and include an exception for financial liabilities settled in cash using an electronic payment system allowing derecognition before the settlement date under specific conditions. The Amendments do not introduce any exception allowing for earlier derecognition of financial assets. Instead, the new application guidance only specifies that the derecognition date for financial assets must be determined in line with IFRS 9.3.2.3. This is when the contractual rights to the cash flows expire or when the asset is transferred. [IFRS 9.B3.1.2A]. The Basis for Conclusions clarify that in the absence of having access to the cash, a confirmation from a debtor that a payment instruction has been initiated does not lead to the expiry of the right to receive cash. It is only when the cash is received that such a right expires, [IFRS 9.BC3.38, IFRS 9.BC3.60].

In the case of cheques, the IASB considered that the completion of the payment remains subject to settlement risk that is more than insignificant until the cash is delivered. [IFRS 9.BC3.55]. This has the consequential impact that entities that have adopted the Amendments are unable to derecognise a financial asset for which a cheque is received until the amount is cleared with the entity's bank account.

Prior to the Amendments, there was no explicit statement in the Standard or Basis for Conclusions that a receivable can only be derecognised when cash is received. Therefore, entities may have derecognised financial assets at an earlier point.

How we see it

Given that the IASB had to issue Amendments to the standards to clarify the requirements in this area, in our view, an entity is not required to change its accounting policy on the timing of derecognition of a financial asset to conform with the Amendments until when those are adopted. At that point, it can make use of the transitional guidance in IFRS 9.7.2.48.

3.5.1 Renegotiation of the terms of an asset

It is common for a borrower, particularly but not necessarily when in financial difficulties, to approach its major creditors for a renegotiation or a restructuring of its loans. The restructuring may involve a modification to the terms of a loan or an exchange of one debt instrument issued by the borrower for another. In these circumstances, IFRS 9 contains accounting requirements for the borrower to apply which address whether the restructured debt shall be regarded as:

- The continuation of the original liability, albeit with recognition of a modification gain or loss in profit or loss (see section 6.2 and particularly section 6.2.6 below)

Or

- A new financial liability which replaces the original liability that is hence derecognised. In this case the borrower would recognise a gain or loss based on the difference between the fair value of the restructured debt and the carrying amount of the original liability (see section 6.2 below). [IFRS 9.3.3.2, IFRS 9.B3.3.6].

However, IFRS 9 does not contain substantive guidance on when a modification of a financial asset shall result in derecognition. Rather, the Basis for Conclusions simply states that some modifications of contractual cash flows result in derecognition of a financial instrument and the recognition of a new instrument, but frequently they do not. [IFRS 9.BC5.216, IFRS 9.BC5.227].

The IFRS IC acknowledged that determining when a modification of an asset should result in its derecognition is an issue that arises in practice and considered undertaking a narrow-scope project to clarify the requirements of IFRS 9. However, in May 2016 the IFRS IC concluded that the broad nature of the issue meant it could not be resolved in an efficient manner and decided not to further consider such a project.⁶ Following the Post Implementation Review of IFRS 9 - Classification and Measurement, the IASB decided to add a research pipeline project to consider whether it should clarify the requirements in IFRS 9 for modifications of financial assets and liabilities, the application of the effective interest method to floating-rate financial instruments and the interaction of these two areas,⁷ see also section 9.1 below. In June 2025, the IASB added a standard-setting work plan.⁸ An exposure draft is expected in the second half of 2026.

Consequently, given the limited guidance as to which modifications of financial assets should lead to derecognition, there is diversity in practice in this area. Entities need to apply judgement in developing an appropriate accounting policy for determining which modifications of financial assets do, or do not, lead to derecognition of the original asset and recognition of a new asset. Examples of common contractual modifications are included in Chapter 46.

Changes that may result in derecognition, individually or in tandem with others, depending on the facts and circumstances, include a change in the currency or in the basis of interest calculation (such as moving from fixed to floating) so that the original effective interest rate would no longer provide an appropriate measure of interest income, the introduction of significant new features into the instrument, such as adding a profit participation to a loan agreement, particularly where the characteristics of the asset would no longer satisfy the criteria of IFRS 9 to be recorded at amortised cost (see Chapter 44), or a significant extension to the term of the instrument.

However, where the modification is part of a troubled debt restructuring, the objective of the changes is usually to maximise recovery of the original contractual cash flows rather than to originate a new asset on current market terms.

In some instances, when an entity modifies a financial asset, it concludes that it must derecognise the old instrument and recognise a new instrument at fair value with a new effective interest rate, see Chapter 45. A worked example of a modification of a financial liability that results in derecognition is set out in Illustration 6-5 at section 6.2.7 below. The accounting treatment for modified assets and liabilities that are derecognised are mostly identical. There are two differences to note for financial assets: (i) any previously held ECL provision will be released and (ii) the new asset may be credit impaired at initial recognition, see Chapter 47 and Chapter 47.

IFRS 9 contains requirements on accounting for the modification of a financial asset when its contractual cash flows are renegotiated or otherwise modified and the asset is not derecognised. In those cases the entity shall recalculate the gross carrying amount of the financial asset and recognise a modification gain or loss in profit or loss. The gross carrying amount is recalculated as the present value of the renegotiated or modified contractual cash flows, discounted at the financial asset's original effective interest rate (or credit-adjusted effective interest rate for purchased or originated credit-impaired financial assets) or, when applicable, the revised effective interest rate calculated in accordance with IFRS 9.6.5.10. Any costs or fees incurred adjust the carrying amount of the modified financial asset and are amortised over the remaining term of the modified financial asset. [IFRS 9.5.4.3]. These requirements are considered in more detail in Chapter 46.

In August 2020 the IASB issued amendments to IFRS 9 to provide guidance on how to account for modifications of a financial asset due to the reform of interbank offered rates (see section 3.5.4 below).

3.5.2 IFRS IC discussions on asset restructuring in the context of Greek government debt

In February 2012, the Greek government announced the terms of a restructuring of certain of its issued bonds. One aspect involved the exchange of 31.5% of the principal amount of the bonds for twenty new bonds with different maturities and interest rates. The remaining portions of the bonds were either forgiven or exchanged for other securities issued by the European Financial Stability Facility, a SPE established by Eurozone states.

Soon afterwards, the IFRS IC was asked to address the appropriate accounting treatment for certain aspects of the restructuring, which they did initially in May 2012. One question the IFRS IC considered was whether the exchange of 31.5% of the principal amount of the original bonds for new bonds could be regarded as a continuation of that portion of the original asset or whether that portion should also be derecognised (it being widely accepted that the remaining portions of the bonds should be derecognised).

The IFRS IC first addressed whether the exchange should be regarded as a transfer. They noted that the bonds were transferred back to the issuer rather than to a third party and, as a consequence, concluded this particular restructuring should not be regarded as a transfer (see section 3.6.1 below). Instead, it would be evaluated to determine whether it amounted to an actual or in-substance expiry or extinguishment of the original cash flows.

The staff analysis was clear that a modification of terms can result in expiry of the asset's original rights to cash flows, although it would not always do so. This is because it is implicit within the requirements for measuring impairment losses that a modification would sometimes be regarded as a continuation of the original, albeit impaired, asset. Therefore, an entity would assess the modifications made against the notion of 'expiry' of the rights to the cash flows.⁹

The staff analysis indicated that the 'hierarchy' in IAS 8 *Accounting Policies, Changes in Accounting Estimates and Errors* would be applied in developing an appropriate accounting policy. Whilst this requires the application of judgement, it is not an absolute discretion. Consequently, it would be appropriate to analogise, at least to some extent, to those requirements in IFRS 9 applying to modifications and exchanges of financial liabilities, particularly the notion of 'substantial modification' and the fact that modifications and exchanges between an existing lender and borrower are seen as equivalent (see section 6.2 below). However, applying the '10% test' to determine whether a modification is substantial would not always be appropriate.

The IFRS IC did not explicitly conclude on this part of the staff analysis, particularly the question of when it would be appropriate to regard a modification or exchange as the expiry or in-substance extinguishment of the original asset. Instead, they simply noted that, in their view, derecognition of the original Greek government bonds would be the appropriate accounting treatment however this particular transaction was assessed, i.e., whether it was viewed as (a) an actual expiry of the rights of the original asset or (b) as a substantial modification that is accounted for as an extinguishment of the original asset (because of the extensive changes in the assets' terms). An agenda decision setting out the IFRS IC's conclusions was published in September 2012.¹⁰

Whilst that discussion resolved most of the issues associated with the restructuring of Greek government bonds, the wider topic continues to require the application of judgement and, as a result, potentially leads to inconsistent approaches being applied by different entities.

3.5.3 Novation of contracts to intermediary counterparties

A change in the terms of a contract may take the legal form of a 'novation'. In this context novation means that the parties to a contract agree to change that contract so that an original counterparty is replaced by a new counterparty.

For example, a derivative between a reporting entity and a bank may be novated to a central counterparty (CCP) as a result of the introduction of new laws or regulations. In these circumstances, the IASB explains that through novation to a CCP the contractual rights to cash flows from the original derivative have expired and as a consequence the novation meets the derecognition criteria for a financial asset. [IFRS 9.BC6.336, IFRS 9.BC6.337]. The novation to the CCP also releases the parties from their original obligations and the novation would therefore also meet the derecognition criteria for a financial liability, as discussed in section 6 below. Consequently, the novation of a derivative to a CCP would be accounted for as the derecognition of the original derivative and the recognition of the (new) novated derivative.

⁹ [IASB Staff Paper 10-A](#), Project: *New items for consideration*, Topic: *IAS 39 Financial Instruments: Recognition and Measurement - Derecognition of financial asset*, IFRS Interpretations Committee Meeting, May 2012, paras. 32-36. Available on the IFRS Foundation's website.

¹⁰ [IFRIC Update](#), September 2012, available on the IFRS Foundation's website.

How we see it

Whilst the IASB reached the above conclusion in relation to novations of over-the-counter derivatives, it is our view that the principle is applicable to all novations of contracts underlying a financial instrument. Accordingly, when a counterparty changes as a result of a novation, the financial instrument shall be derecognised and a new financial instrument shall be recognised.

Although such a novation may not be expected to give rise to a significant gain or loss when the financial instrument derecognised and the new financial instrument recognised are both measured at fair value through profit or loss, the bid/ask spread and the effect of change in counterparty on credit risk may cause some value differences. Furthermore, a novation may result in discontinuation of hedge accounting if the original financial instrument was a derivative designated in a hedging relationship (see Chapter 49 for further details).

3.5.4 Interbank Offered Rate (IBOR) Reform

Following recommendations from the Financial Stability Board, there have been various initiatives to replace current benchmark interest rates, such as interbank offered rates like LIBOR, with nearly risk-free rates. In view of these initiatives and the resulting uncertainty around the long-term viability of IBORs, the IASB added a two-stage project to its agenda. The first stage was to consider financial reporting issues that may arise prior to the replacement of IBORs; and the second stage was to consider issues arising from changes to contractual cash flows required by the replacement of IBORs. IBOR reform and the IASB's project, including how the derecognition requirements apply to consequential modifications of financial instruments, are discussed in more detail in the *Supplement: IBOR Reform*.

3.5.5 Write-offs

An entity is required to directly reduce the gross carrying amount of a financial asset when it has no reasonable expectations of recovery. Such a write-off is regarded as the asset being derecognised - effectively it is seen as an in-substance expiry of the associated rights. Write-offs can also relate to a portion of an asset. For example, consider an entity that plans to enforce the collateral on a financial asset and expects to recover no more than 30% of the financial asset from the collateral. If the entity has no reasonable prospects of recovering any further cash flows from the financial asset, it must write off the remaining 70%. [IFRS 9.5.4.4, IFRS 9.B3.2.16(r), IFRS 9.B5.4.9].

3.6 Has the entity 'transferred' the asset?

An entity is regarded by IFRS 9 as 'transferring' a financial asset if, and only if, it either: [IFRS 9.3.2.4]:

- (a) Transfers the contractual rights to receive the cash flows of the financial asset (see section 3.6.1 below)

Or

- (b) Retains the contractual rights to receive the cash flows of the financial asset, but assumes a contractual obligation to pay the cash flows on to one or more recipients in an arrangement that meets the conditions in section 3.6.2 below (a so-called 'pass-through arrangement')

The latter might be the case where the entity is a SPE or trust, and issues to investors beneficial interests in financial assets that it owns and provides servicing of those assets. [IFRS 9.B3.2.2].

3.6.1 Transfers of contractual rights to receive cash flows

The discussion in this section refers to Box 4 in Figure 3-1 in section 3.2 above.

IFRS 9 does not define what is meant by the phrase "transfers the contractual rights to receive the cash flows of the financial asset" in (a) in section 3.6 above, possibly on the assumption that this is self-evident. However, this is far from the case, since the phrase raises a number of questions of interpretation.

There are two key uncertainties about the meaning of ‘transferring the contractual rights’ (which in turn determines whether a transaction falls within (a) or (b) in section 3.6 above):

- Whether it is restricted to transfers of legal title only or also encompasses transfers of equitable title or an equitable interest (see section 3.6.1.A below)
- And
- The effect of conditions attached to the transfers (see section 3.6.1.B below)

In the context of the restructuring of Greek government bonds (see section 3.5.2 above), the IFRS IC considered whether an exchange of debt instruments between a borrower and a lender should be regarded as a transfer. It was noted that the bonds were transferred back to the issuer rather than to a third party and, as a consequence, it was agreed that this particular restructuring should not be regarded as a transfer.¹¹ However, it was noted during the IFRS IC’s discussion and in the comment process that applying such a conclusion more widely might not always be appropriate, e.g., in the case of a short-term sale and repurchase agreement over a bond with the bond issuer or the simple repurchase of a bond by the issuer for cash.

3.6.1.A Meaning of ‘transfers the contractual rights to receive the cash flows’

In many jurisdictions, the law recognises two types of title to property: (a) legal title; and (b) ‘equitable’, or beneficial title. In general, legal title defines who owns an asset at law and equitable title defines who is recognised as entitled to the benefit of the asset. Transfers of legal title give the transferee the ability to bring an action against a debtor to recover the debt in its own name. In equitable transfers, however, the transferee joins the transferor in an action to sue the debtor for recovery of debt. As noted above, the issue here is whether ‘transfers of contractual rights’ are limited to transfers of legal title.

In a typical securitisation transaction across many jurisdictions, the transfer of contractual rights to receive cash flows are achieved via equitable or beneficial transfer of title in that asset, as the transfer of legal title in the asset would simply not be possible without either:

- A tri-partite agreement between the corporate entity, the finance provider and the debtor
- Or
- A clause in the standard terms of trade allowing such a transfer at the sole discretion of the corporate entity without the express consent of the debtor, so that transfer can be effected by a subsequent bi-partite agreement between the corporate entity and the finance provider.

The consent of the debtor is not normally obtained, or indeed practically obtainable, in many securitisations and similar transactions. In these arrangements, all cash flows that are collected are contractually payable to a new eventual recipient - i.e., the debtor continues to pay the transferor, while the transferor loses the right to retain any cash collected from the debtor without actually transferring the contract itself.

In March 2006 the IFRS IC began to consider whether there can be a transfer of the contractual right to receive cash flows in an equitable transfer.¹² The IFRS IC had already concluded, in November 2005, that retaining servicing rights (i.e., continuing to administer collections and distributions of cash as agent for the transferee) does not in itself preclude derecognition.¹³ However, the IFRS IC then considered whether retention by the transferor of the contractual right to receive the cash from debtors for distribution on to other parties (as must inevitably happen if debtors are not notified) means that such a transaction does not meet test (a) in section 3.6 above, and thus must meet test (b) (pass-through), as discussed in section 3.6, in order to achieve derecognition. The IFRS IC referred this issue to the IASB, which indicated in September 2006 that:

“A transaction in which an entity transfers all the contractual rights to receive the cash flows (without necessarily transferring legal ownership of the financial asset), would not be treated as a pass-through. An example might be a situation in which an entity transfers all the legal rights to specifically identified cash flows of a financial asset (for example, a transfer of the interest or principal of a debt instrument). Conversely, the pass-through test would be applicable when the entity does not transfer all the contractual rights to cash flows of the financial asset, such as disproportionate transfers.”¹⁴

11 [IFRIC Update](#), September 2012, available on the IFRS Foundation’s website.

12 [Information for Observers](#), IFRS IC Meeting, March 2006, available on the IFRS Foundation’s website.

13 [IFRIC Update](#), November 2005, available on the IFRS Foundation’s website.

14 [IASB Update](#), September 2006, available on the IFRS Foundation’s website.

The statement that such a transaction ‘would not be treated as a pass-through’ means (in terms of Figure 3-1 in section 3.2 above) that the answer to Box 4 is ‘Yes’, such that the pass-through test in Box 5 (see section 3.6.2 below) is by-passed.

How we see it

The IASB’s conclusion appears to concede that the references in IFRS 9 to a transfer of the ‘contractual’ right to cash flows was intended to include an equitable transfer of those rights, a conclusion that the IASB repeated in its April 2009 Exposure Draft - *Derecognition*. In our view, the transfer of the contractual rights to cash flows could encompass both the transfer of legal title in the asset as well as transfer of equitable or beneficial title in the asset.

3.6.1.B Transfers subject to conditions

An entity may transfer contractual rights to cash flows but subject to conditions. The IFRS IC identified the following main types of condition¹⁵:

- *Conditions relating to the existence and legal status of the asset at the time of the transfer*
These include normal warranties as to the condition of the asset at the date of transfer and other guarantees affecting the existence and accuracy of the amount of the receivable that may not be known until after the date of transfer.
- *Conditions relating to the performance of the asset after the time of transfer*
These include guarantees covering future default, late payment or changes in credit risk, guarantees relating to changes in tax, legal or regulatory requirements, where the buyer may be able to require additional payments if it is disadvantaged or - in some cases - demand reversal of the transaction, or guarantees covering future performance by the seller that might affect the recoverable amount of the debtor.

All securitisations (and indeed, most transfers, whether of financial or non-financial assets) include express or implied warranties regarding the condition of the asset at the date of transfer.

How we see it

In the case of a securitisation of credit card receivables, these might include a representation that, for example, all the debtors transferred are resident in a particular jurisdiction, or have never been in arrears for more than one month in the previous two years. In our view, such warranties do not affect whether or not the transaction achieves derecognition. However, the ability of the transferor to reliably identify the receivables eligible to be transferred under such conditions is key to determine the scope of the derecognition analysis.

It is a different matter when it comes to guarantees of post-transfer performance.

In September 2006, the IASB expressed the view that neither conditions relating to the existence and value of transferred cash flows at the date of transfer nor conditions relating to the future performance of the asset would affect whether the entity has transferred the contractual rights to receive cash flows¹⁶ (i.e., Box 4 in Figure 3-1 in section 3.2 above). In other words, a transaction with such conditions that otherwise met the criteria in Box 4 would not be subject to the pass-through test in Box 5.

However, the existence of conditions relating to the future performance of the asset might affect the conclusion related to the transfer of risks and rewards (i.e., Box 6 in Figure 3-1 in section 3.2 above) as well as the extent of any continuing involvement by the transferor in the transferred asset (i.e., Box 9 in Figure 3-1 in section 3.2. above).¹⁷

An entity must take a view that is consistent with its policies on these matters and, as in these other cases, hold this view consistently when considering the derecognition of any financial asset.

¹⁵ [IFRIC Update](#), March 2006, available on the IFRS Foundation’s website.

¹⁶ [IASB Update](#), September 2006, available on the IFRS Foundation’s website.

¹⁷ [IASB Update](#), September 2006, available on the IFRS Foundation’s website.

A transfer of contractual rights might further be subject to an offsetting arrangement between the contract parties. An example of a two-party offset arrangement is when the original debtor (e.g., a borrower or customer) has the right to offset amounts it is owed by the transferor (e.g., balances in a deposit account or arising from a credit note issued by the transferor) against the transferred asset. If such a right is exercised after the asset is transferred the transferor would be required to compensate the transferee.

How we see it

This would not, in our view, normally affect whether the entity has transferred the contractual rights to receive the cash flows of the original financial asset. Payments made by the transferor to the transferee as a result of the right of offset being exercised by the debtor simply transfer to the transferee the value the transferor obtained when its liability to the original debtor was settled.

There may also be tripartite offset arrangements where a party other than the original debtor (e.g., a subcontractor) has such offset rights.¹⁸

3.6.2 Retention of rights to receive cash flows subject to obligation to pay over to others (pass-through arrangement)

The discussion in this section refers to Box 5 in Figure 3-1 in section 3.2 above.

It is common in certain securitisation and debt sub-participation transactions (see section 3.3 above) for an entity to enter into an arrangement whereby it continues to hold the contractual rights to the cash flows and collect cash receipts from a financial asset (or more typically a pool of financial assets), but is obliged to pass on those receipts to a third party that has provided finance in connection with the financial asset. Whilst the term 'pass-through' for these arrangements does not actually appear in IFRS 9, it has become part of the language of the financial markets.

Under IFRS 9, an arrangement whereby the reporting entity retains the contractual rights to receive the cash flows of a financial asset (the 'original asset'), but assumes a contractual obligation to pay the cash flows to one or more recipients (the 'eventual recipients') is regarded as a transfer of the original asset if, and only if, all of the following three conditions are met:

- (a) The entity has no obligation to pay amounts to the eventual recipients unless it collects equivalent amounts from the original asset. Short-term advances by the entity with the right of full recovery of the amount lent plus accrued interest at market rates do not violate this condition (see section 3.6.2.B below).
- (b) The entity is prohibited by the terms of the transfer contract from selling or pledging the original asset other than as security to the eventual recipients for the obligation to pay them cash flows.
And
- (c) The entity has an obligation to remit any cash flows it collects on behalf of the eventual recipients without material delay. In addition, the entity is not entitled to reinvest such cash flows, except in cash or cash equivalents as defined in IAS 7 *Statement of Cash Flows* (see Chapter 36) during the short settlement period from the collection date to the date of required remittance to the eventual recipients, with any interest earned on such investments being passed to the eventual recipients.

[IFRS 9.3.2.5].

These conditions are discussed further in section 3.6.2.D below.

IFRS 9 notes that an entity that is required to consider the impact of these conditions on a transaction is likely to be either:

- The originator of the financial asset in a securitisation transaction (see section 3.3 above)
Or
- A group that includes a consolidated SPE that has acquired the financial asset and passes on cash flows to unrelated third-party investors [IFRS 9.B3.2.3]

¹⁸ Information for Observers, IFRS IC Meeting, March 2006.

IFRS 9 does not address whether it is necessary for a pass-through arrangement to be able to survive the bankruptcy of the transferor in order to be considered a transfer. Consequently, there is no explicit requirement in the standard to consider the likelihood of the transferor's bankruptcy when assessing pass-through arrangements. This issue was discussed by the IASB in its April 2009 Exposure Draft *Derecognition*, where it was proposed that bankruptcy remoteness would not form part of the derecognition model. This was seen at the time as an intentional divergence from US GAAP, which requires transferred financial assets to be legally isolated from the transferor, its consolidated affiliates and its creditors, even in bankruptcy.¹⁹ In practice, if the transferred assets are held in a ring-fenced structured entity this may protect cash flows to the transferee in the event of the transferor's bankruptcy.

We note that some transfer arrangements include a right by the transferor to use the cash flows collected under the pass-through arrangement to net settle other amounts owed by the transferee to the transferor. This means that, rather than a physical remittance of cash under IFRS 9.3.2.5(c), a net settlement occurs. On its own, net settlement would not preclude IFRS 9.2.3.5(c) from being met, as the form of settlement does not change the transferor's obligation to transfer the value embedded in the cash flows to the transferee without material delay.

3.6.2.A Recourse to originator

The conditions in section 3.6.2 above clearly have the effect that an arrangement that does not transfer the contractual rights to receive the cash flows and provides for direct recourse to the originator usually does not meet the definition of a 'transfer' for the purposes of pass-through and therefore does not qualify to be considered for derecognition. Direct recourse would include an arrangement whereby part of the consideration for the financial asset transferred was deferred depending on the performance of the asset.

How we see it

In our view, however, certain techniques for providing indirect recourse do not breach the conditions for transfer for the purposes of pass-through. These include, for example, the provision of certain types of insurance provided that the investors' only recourse is to the insurance policy (see section 3.6.2.C below).

If, however, the arrangement involves a transfer of the contractual rights to receive the cash flows, the recourse will have an impact on the originator's analysis of the risks and rewards. This is dealt with in more detail in section 4.3 below.

3.6.2.B Short-term loan facilities

Enhancing a securitised asset with the provision of loan facilities to meet temporary shortfalls as a result of slow payments from the asset would preclude an arrangement being regarded as a pass-through unless the facilities:

- Are made on a 'short-term' basis
- Are repayable irrespective of whether the slow payments are eventually received
- And
- Bear interest at market rates

The purpose of these restrictions is to ensure that IFRS 9 allows derecognition of assets subject to such facilities only where the facilities are providing a short-term cash flow benefit to the investor, and not when they effectively transfer slow payment risk back to the originator (as would be the case if the originator made significant interest-free loans to the investor). Clearly, therefore, the circumstances in which such funds can be advanced must be very tightly defined if pass-through is to be achieved.

¹⁹ Exposure Draft [ED/2009/3: Derecognition](#), April 2009. Available on the IFRS Foundation's website.

3.6.2.C Insurance protection

The implications of the derecognition and pass-through requirements of IFRS 9 for transfers of groups of financial assets including insurance contracts have been considered by the IFRS IC and the IASB but their tentative conclusions were withdrawn. For a discussion of the issues and the alternative interpretations of 'similar' assets, see section 3.4.2.B above.

How we see it

The conditions for 'pass-through arrangements' are not, in our view, breached by the originator purchasing an insurance contract for the benefit of investors in the event of a shortfall in cash collections from the securitised assets, provided that the investors' only recourse is to the insurance policy. In other words, the originator cannot give a guarantee to investors to make good any shortfalls should the insurer become insolvent, nor can the originator provide any support to the insurer through a guarantee arrangement or a reinsurance contract.

3.6.2.D Treatment of collection proceeds

Securitisation contracts rarely require any amount received on the securitised assets to be immediately transferred to investors. This is for the obvious practical reason that it would be administratively inefficient, in the case of a securitisation of credit card receivables for example, to transfer the relevant portion of each individual, and relatively small, cash flow received from the hundreds, if not thousands, of cards in the portfolio. Instead, it is usual for transfers to be made in bulk on a periodic basis (e.g., weekly or monthly). This raises the question of what happens to the cash in the period between receipt by the issuer and onward transfer to the investors.

IFRS 9 requires cash flows from transferred financial assets for which derecognition is sought to be:

- Passed to the eventual recipients 'without material delay'
- And
- Invested only in cash or cash equivalents as defined in IAS 7 entirely for the benefit of the investors (see condition (c) in section 3.6.2 above)

These requirements mean that many securitisation arrangements may well fail to satisfy the pass-through test in section 3.6.2 above.

How we see it

The IASB does not expand further on the term 'without material delay'. It is not, in our view, intended to require settlement to noteholders on an unrealistically frequent basis such as daily, although we would normally expect payments to be made by the next quarterly coupon payment date to meet this condition.

Suppose that a credit card issuer wishes to raise five-year finance secured on its portfolio of credit card receivables. The assets concerned are essentially short term (being in most cases settled in full within four to eight weeks), whereas the term of the borrowings secured on them is longer. In practice, what generally happens is that, at the start of the securitisation, a 'pool' of balances is transferred to a securitisation SPE. The cash receipts from that 'pool' are used to pay interest on the borrowings, and to fund new advances on cards in the 'pool' or to purchase other balances. Such an arrangement, commonly referred to as a 'revolving' structure, appears to breach the requirement of the pass-through tests to:

- Pass on cash receipts without material delay (since only the amount of cash receipts necessary to pay the interest on the borrowings is passed on, with the balance being reinvested until the principal of the borrowings falls due).
- And
- Only invest in cash or cash equivalents as defined in IAS 7 in the period prior to passing them onto the investor. This is because the cash not required to pay interest on the borrowings is invested in further credit card receivables, which are not cash or cash equivalents as defined in IAS 7.

The IFRS IC confirmed in November 2005 that most 'revolving' structures do not meet the requirements of the pass-through test for funds to be passed on without material delay and to be invested only in cash and cash equivalents.²⁰

In practice, we have observed the pass-through tests are applied very strictly such that any arrangement that provides for even a small tranche of the interest from such short-term deposits to be retained by or for the benefit of the originator will not satisfy the criteria for transfer under IFRS 9. Moreover, IFRS 9 requires that the reporting entity 'is not entitled' to invest the cash other than in cash or cash equivalents as described above. Thus, it appears that the criteria for transfer are not satisfied merely where the entity does not in fact invest the cash in any other way - it must be contractually prohibited from doing so. In practice, this is often achieved by having the funds paid into a trustee bank account that can be used only for the benefit of the providers of finance. Arrangements where re-investment occurs could meet the pass-through requirements if the investor has the substantive ability to choose whether or not to reinvest at the point where the re-investment needs to be made, and all other conditions in IFRS 9 3.2.5 are met. This is because in such a scenario the transferee is effectively realising the underlying cash flows and re-investing them, with cash flows happening on a net basis for operational ease.

The strict requirements of IFRS 9 in respect of cash received from assets subject to a pass-through arrangement raise the related, but broader, issue of the appropriate treatment of client money which is discussed in section 8 below.

3.6.2.E Transfers of non-optional derivatives along with a group of financial assets

As discussed in section 3.4.2 above, interest rate swaps that are transferred along with a group of non-derivative financial assets may be derecognised only when any associated obligation is also discharged, cancelled or expires (see section 6 below). This is because the pass-through criteria do not apply to a transfer of an interest rate swap which can be either a financial asset or a financial liability.

In a securitisation transaction involving the equitable transfer of an interest rate swap to an SPE, the swap would continue to be recognised by the transferor. The ongoing accounting consequences of this are less clear. The swap must clearly continue to be measured at fair value through profit or loss in accordance with the general requirement of IFRS 9 for the measurement of derivatives not in a hedging relationship (see Chapter 42). However, this would have the effect that the reporting entity reflected gains and losses in the income statement for a derivative in which it no longer has a beneficial interest. In such a case, the entity would presumably recognise the notional back-to-back swap which it has effectively entered into with the transferee, so as to offset the income statement effect of the original swap.

3.6.2.F 'Empty' subsidiaries or SPEs

If an entity enters into a transaction whereby:

- The entity transfers an asset to a subsidiary or SPE.
- And
- The subsidiary or SPE transfers the asset to noteholders on terms that satisfy the pass-through derecognition criteria in IFRS 9, as discussed in sections 3.2 and 3.6.2 above.

The overall effect will be that the individual financial statements of the subsidiary or SPE will include neither the transferred asset nor the finance raised from noteholders. This may well mean that the financial statements show nothing apart from the relatively small amount of equity of the entity and any related assets. This analysis is likely to be applicable only for relatively simple transfers, and not, for example, when derivatives are transferred along with the non-derivative assets.

²⁰ [IFRIC Update](#), November 2005, available on the IFRS Foundation's website.

3.7 Has the entity transferred or retained substantially all the risks and rewards of ownership?

The discussion in this section refers to Boxes 6 and 7 in Figure 3-1 in section 3.2 above.

Extract from IFRS 9

- 3.2.6** When an entity transfers a financial asset (see paragraph 3.2.4), it shall evaluate the extent to which it retains the risks and rewards of ownership of the financial asset. In this case:
- (a) if the entity transfers substantially all the risks and rewards of ownership of the financial asset, the entity shall derecognise the financial asset and recognise separately as assets or liabilities any rights and obligations created or retained in the transfer.
 - (b) if the entity retains substantially all the risks and rewards of ownership of the financial asset, the entity shall continue to recognise the financial asset.
 - (c) if the entity neither transfers nor retains substantially all the risks and rewards of ownership of the financial asset, the entity shall determine whether it has retained control of the financial asset. In this case:
 - (i) if the entity has not retained control, it shall derecognise the financial asset and recognise separately as assets or liabilities any rights and obligations created or retained in the transfer.
 - (ii) if the entity has retained control, it shall continue to recognise the financial asset to the extent of its continuing involvement in the financial asset (see paragraph 3.2.16).

[IFRS 9.3.2.6].

IFRS 9 clarifies that the transfer of risks and rewards is evaluated by comparing the entity's exposure, before and after the transfer, to the variability in the amounts and timing of the net cash flows of the transferred asset. [IFRS 9.3.2.7]. Often it will be obvious whether the entity has transferred or retained substantially all risks and rewards of ownership. In other cases, it will be necessary to determine this by computing and comparing the entity's exposure to the variability in the present value (discounted at an appropriate current market interest rate) of the future net cash flows before and after the transfer. All reasonably possible variability in net cash flows is considered, with greater weight being given to those outcomes that are more likely to occur. [IFRS 9.3.2.8].

In some circumstances it may be appropriate to consider whether substantially all the risks and rewards of an asset have been transferred as a result of the cumulative effect of two separate transactions (see section 3.7.5 below).

3.7.1 Transfers resulting in transfer of substantially all risks and rewards

An entity has transferred substantially all the risks and rewards of ownership of a financial asset if its exposure to the variability in the amounts and timing of the net cash flows of the transferred asset is no longer significant in relation to the total variability. IFRS 9 gives the following examples of transactions that transfer substantially all the risks and rewards of ownership:

- An unconditional sale of a financial asset.
 - A sale of a financial asset together with an option to repurchase the financial asset at its fair value at the time of repurchase (since this does not expose the entity to any risk of loss or give any opportunity for profit).
 - A sale of a financial asset together with a put or call option that is deeply out of the money (i.e., an option that is so far out of the money it is highly unlikely to go into the money before expiry).
- Or
- The sale of a fully proportionate share of the cash flows from a larger financial asset in an arrangement, such as a loan sub-participation, that satisfies the criteria for a 'transfer' in section 3.6 above. [IFRS 9.3.2.7, IFRS 9.B3.2.4].

Such transactions are discussed in more detail in section 4 below.

It is important to note that, in order for derecognition to be achieved, it is necessary that the entity's exposure to the variability in the amounts and timing of the net cash flows of the transferred asset is considered not in isolation, but 'in relation to the total variability' (see above). Thus, derecognition is not achieved simply because the entity's remaining exposure to the risks or rewards of an asset is small in absolute terms. It has also become clear, from the IFRS IC and IASB's discussions described in section 3.4.2 above, that derecognition also depends on the interpretation of 'asset' and of groups of similar assets that is applied by the entity and how this determines the total variability to be considered as a reference before and after the sale.

3.7.2 Transfers resulting in retention of substantially all risks and rewards

An entity has retained substantially all the risks and rewards of ownership of a financial asset if its exposure to the variability in the present value of the future net cash flows from the financial asset does not change significantly as a result of the transfer. [IFRS 9.3.2.7]. IFRS 9 gives the following examples of transactions in which an entity has retained substantially all the risks and rewards of ownership: [IFRS 9.B3.2.5]

Extract from IFRS 9

- B3.2.5 Examples of when an entity has retained substantially all the risks and rewards of ownership are:
- (a) a sale and repurchase transaction where the repurchase price is a fixed price or the sale price plus a lender's return;
 - (b) a securities lending agreement;
 - (c) sale of a financial asset together with a total return swap that transfers the market risk exposure back to the entity;
 - (d) a sale of a financial asset together with a deep in-the-money put or call option (ie an option that is so far in the money that it is highly unlikely to go out of the money before expiry); and
 - (e) sale of short-term receivables in which the entity guarantees to compensate the transferee for credit losses that are likely to occur.

Such transactions are discussed in more detail in section 4 below.

3.7.3 Transfers resulting in neither transfer nor retention of substantially all risks and rewards

IFRS 9 gives the following examples of transactions in which an entity has neither transferred nor retained substantially all the risks and rewards of ownership:

- A sale of a financial asset together with a put or call option that is neither deeply in the money nor deeply out of the money. [IFRS 9.B3.2.16(h), IFRS 9.B3.2.16(i)]. The effect of such an option is that the transferor will have either (in the case of purchased call option) capped its exposure to a loss in value of the asset but have potentially unlimited access to increases in value or (in the case of a written put option) capped its potential access to increases in value in the asset but assumed potential exposure to a total loss in value of the asset.
And
- A sale of 90% of a loan portfolio with significant transfer of prepayment risk, but retention of a 10% interest, with losses allocated first to that 10% retained interest. [IFRS 9.B3.2.17].

Such transactions are discussed in more detail in section 4 below.

3.7.4 Evaluating the extent to which risks and rewards are transferred - practical example

The following Illustration shows one approach to evaluating the extent to which risks and rewards associated with a portfolio of assets have been transferred.

Illustration 3-1: Risks and rewards analysis - variability in the amounts and timing of net cash flows

Entity X sells a portfolio of trade receivables with a total face value of CU1 million and an average due date of 45 days from the issuance of the invoice to Entity Y, an unrelated third party. After the sale, Entity X does not retain any residual benefits in the receivables. However, Entity X guarantees losses on the transferred portfolio up to a percentage of the total face value. Default losses, including late payments, as a percentage of face value ranged historically from 3% to 7%.

Assume the following two hypothetical situations:

- Fact pattern 1 - Entity X guarantees first losses on the portfolio up to 3.5% of the total face value.
- Fact pattern 2 - Entity X guarantees first losses on the portfolio up to 5% of the total face value.

The following calculations illustrate one possible approach for calculating the exposure to the variability in the amounts and timing of net cash flows.

Under this approach the reporting entity (Entity X) determines a number of reasonably possible scenarios that reflect the expected variability in the amounts and timing of net cash flows; these scenarios are then assigned a probability, with greater weighting being given to those outcomes that are more likely to occur. Next, Entity X calculates the expected future net cash flows for each scenario, discounted using an appropriate current market rate. The expected variability is then calculated using an appropriate statistical technique. In this example, the expected variability is calculated by first calculating the differences between the discounted expected cash flows for each scenario and the expected value (i.e., the sum of the probability weighted discounted expected cash flows for all possible scenarios) and then adding up these individual probability-weighted differences (separately for negative or positive). An alternative, and more statistically sound approach, is to compute the standard deviation considering the square root of the sum of the probability weighted squares of the differences as calculated above (i.e., the discounted expected net cash flows for each scenario minus the expected value). This method requires a significantly greater number of scenarios, with an individually assigned probability, in order to be statistically robust. We have also illustrated this approach in a simplified manner, using five scenarios.

The above steps are duplicated for net cash flows that the transferor, Entity X, remains exposed to after the transfer. Finally, the exposure to expected variability of net cash flows post transfer is compared to the corresponding expected variability before the transfer.

As the receivables are relatively short-term, the calculations below focus primarily on credit risk. For simplicity, the calculations below ignore the effect of discounting.

Fact pattern 1: Entity X guarantees first losses on the portfolio up to 3.5% of total face value.

Based on historical experience and supportable expectations Entity X has defined five scenarios of possible variability, each of which has been assigned a probability based on historical experience and current market information. In practice, obtaining this data may prove more challenging. These scenarios and probabilities are set out below.

Before Transfer

Total face value = CU1,000,000 = A

Possible credit loss	Discounted expected cash flows	Probability	Probability weighted discounted cash flows	Difference	Probability weighted negative variability	Probability weighted positive variability
B	C = A-[A×B]	D	E=C×D	F=C-Σ(E)	G=F×D if F<0	H=F×D if F>0
	CU		CU	CU	CU	CU
3.0%	970,000	3.5%	33,950	23,100	-	808.5
4.0%	960,000	20.0%	192,000	13,100	-	2620
5.0%	950,000	30.0%	285,000	3,100	-	930
6.0%	940,000	35.0%	329,000	(6,900)	(2,415)	-
7.0%	930,000	11.5%	106,950	(16,900)	(1,943.5)	-
		100.0%	946,900		(4,358.5)	4,358.5
					K	K
Probability weighted discounted loss			CU53,100	I=A-Σ(E)		

After Transfer

Total face value = CU1,000,000 = A

Possible credit loss	Discounted expected negative cash flows	Probability	Probability weighted discounted negative cash flows	Difference	Probability weighted negative variability	Probability weighted positive variability
B	$C=[A \times (B)],$ max CU35,000 CU	D	$E=C \times D$ CU	$F=C-\Sigma(E)$ CU	$G=F \times D$ if $F < 0$ CU	$H=F \times D$ if $F > 0$ CU
3.0%	30,000	3.5%	1,050	(4,825)	(168.88)	-
4.0%	35,000	20.0%	7,000	175	-	35.00
5.0%	35,000	30.0%	10,500	175	-	52.50
6.0%	35,000	35.0%	12,250	175	-	61.25
7.0%	35,000	11.5%	4,025	175	-	20.13
		100.0%	34,825		(168.88)	168.88
Probability weighted discounted loss			CU34,825	$M=\Sigma(E)$	L	L
Percentage of variability retained by Entity X				$L \div K$	(3.87%)	3.87%

To avoid a mechanical determination and to leave room for judgement, IFRS 9 does not establish any bright-lines on what constitutes 'substantially all' risks and rewards of ownership. Therefore, judgement is needed to assess what is 'substantially all' in each particular situation considering, for example, the sensitivity of the calculation to certain changes in assumptions.

Assuming that Entity X determined that 'substantially all' represents 90% of total expected variability in the amounts and timing of net cash flows, it will conclude that it has transferred substantially all risks and rewards of ownership, as only 3.87% has been retained.

This conclusion may seem counterintuitive given that Entity X has retained 65.58% of the total expected losses ($M \div I = \text{CU}34,825 \div \text{CU}53,100$). However, IFRS 9 is clear that the transfer of risks and rewards is evaluated by comparing the transferor's exposure, before and after the transfer, to the variability in the amounts and timing of net cash flows of the transferred asset (IFRS 9.3.2.7). In practice, even when factoring with limited recourse, the transferor very often retains exposure to losses in excess of those reasonably expected to arise such that substantially all the variability is retained by the transferor.

The alternative approach mentioned above, is calculated in the following manner. Please note that the inputs to the formulas that are presented below, refer to the before and after transfer scenario respectively:

Possible credit loss	Probability weighted Standard Deviation NPV before transfer	Probability weighted Standard Deviation NPV after transfer
	$F^2 \times D$ CU	$F^2 \times D$ CU
3.0%	18,676,350	814,822
4.0%	34,322,000	6,125
5.0%	2,883,000	9,188
6.0%	16,663,500	10,719
7.0%	32,845,150	3,522
Standard deviation	10,266	919
	A	B
Variability retained (B ÷ A)		8.95%

In this case, the alternative approach would lead to a higher measure of variability retained, but the same conclusion would still apply based on the 90% threshold mentioned above. In practice, a higher number of scenarios may be applied, which may narrow the difference between the two scenarios.

Fact pattern 2: Entity X guarantees first losses on the portfolio up to 5% of the total face value.

Total face value = CU1,000,000 = A

Before Transfer

Possible credit loss	Discounted expected cash flows	Probability	Probability weighted discounted cash flows	Difference	Probability weighted negative variability	Probability weighted positive variability
B	C= A-[A×B]D	E=C×D	F=C-Σ(E)	G=F×D if F<0	H=F×D if F>0	
	CU		CU	CU	CU	CU
3.0%	970,000	3.5%	33,950	23,100	-	808.5
4.0%	960,000	20.0%	192,000	13,100	-	2620
5.0%	950,000	30.0%	285,000	3,100	-	930
6.0%	940,000	35.0%	329,000	(6,900)	(2,415)	-
7.0%	930,000	11.5%	106,950	(16,900)	(1,943.5)	-
		100.0%	946,900		(4,358.5)	4,358.5
					K	K
Probability weighted discounted loss CU53,100			I = A-Σ(E)			

After Transfer

Possible credit loss	Discounted expected negative cash flows	Probability	Probability weighted discounted negative cash flows	Difference	Probability weighted negative variability	Probability weighted positive variability
B	C=[A×(B)], max CU50,000	D	E=C×D	F=C-Σ(E)	G=F×D if F<0	H=F×D if F>0
	CU		CU	CU	CU	CU
3.0%	30,000	3.5%	1,050	-17,300	-605.5	-
4.0%	40,000	20.0%	8,000	-7,300	-1460	-
5.0%	50,000	30.0%	15,000	2,700	-	810
6.0%	50,000	35.0%	17,500	2,700	-	945
7.0%	50,000	11.5%	5,750	2,700	-	310.5
		100.0%	47,300		(-2,065.5)	2,065.5
			M		L	L
			CU			
Probability weighted discounted loss			47,300	M=Σ(E)		
Percentage of variability retained by Entity X				L÷K	(47.39%)	47.39%

Now that Entity X stands ready to cover first losses up to 5%, it is not a surprise that its exposure to variability has increased to 47.39%. This means that Entity X has neither transferred nor retained substantially all risks and rewards of ownership in this case. Again, the fact that the seller now covers, after the sale, 89.08% ($M \div I = \text{CU}38,650 \div \text{CU}41,550$) of the total expected losses is not relevant to the analysis.

Similar to fact pattern 1, we have performed the variability analysis by comparing the standard deviations, before and after transfer.

Possible credit loss	Probability weighted Standard Deviation NPV - before transfer	Probability weighted Standard Deviation NPV - after transfer
	$F^2 \times D$	$F^2 \times D$
	CU	CU
3.0%	18,676,350	10,475,150
4.0%	34,322,000	10,658,000
5.0%	2,883,000	2,187,000
6.0%	16,663,500	2,551,500
7.0%	32,845,150	838,350
Standard deviation	10,266	5,168
	A	B
Variability retained (B÷A)		50.34%

In this case, derecognition will depend on whether the transferee (Entity Y) has the practical ability to sell the trade receivables unilaterally and without imposing additional restrictions on the transfer. The conclusion needs to take into account many factors. For example: (i) whether the transferee has legal title to the transferred receivables; (ii) whether there is a market for the transferred receivables or not; (iii) whether or not the seller has a call option or has written a put option over the transferred receivables; (iv) whether or not the guarantee of Entity X is transferable with the receivables; (v) whether the receivables are 'ring-fenced' in an SPE as a pledge for securities collateralised by the transferred assets, etc. This aspect of the analysis is covered in section 3.8 below.

3.7.5 Transfer of risks on a cumulative basis

The following Illustration shows that derecognition may be achieved by the transfer of substantially all the risks and rewards of ownership in two separate transactions.

Illustration 3-2: Risks and rewards analysis - two separate transactions

Entity X owns a pool of mortgages with a fixed rate of interest of 5%. The mortgages are guaranteed by a government agency and are effectively free of credit risk, but they are subject to variability due to prepayment risk. Entity X sells part of the cash flows from the mortgages (cash flows from the principal and a proportionate share of the interest payments equivalent to a return on the principal of 3%) to Entity Y but indemnifies Entity Y such that Entity Y is not exposed to any of the prepayment variability. Entity X indemnifies Entity Y by agreeing to make a compensatory payment(s) to Entity Y for lost interest on mortgages which are prepaid.

Subsequently, Entity X enters into a second transaction with Entity Z under which Entity Z receives the remaining cash flows from the mortgages and takes on the indemnity to Entity Y such that Entity X is no longer exposed to any prepayment variability.

Entity X assesses the risks and rewards of its interests in the mortgages on a cumulative basis. At the time of the sale to Entity Y, Entity X concludes that it has retained substantially all the risks and rewards of the mortgages because it has retained the prepayment variability and therefore continues to recognise them.

At the time of the transaction with Entity Z, Entity X concludes that it has now transferred substantially all the risks and rewards of the mortgages and therefore derecognises them.

3.8 Has the entity retained control of the asset?

The discussion in this section relates to Boxes 8 and 9 of Figure 3-1 in section 3.2 above.

If the transferring entity has neither transferred nor retained substantially all the risks and rewards of a transferred financial asset, IFRS 9 requires the entity to determine whether or not it has retained control of the financial asset. If the entity has not retained control, it must derecognise the financial asset and recognise separately as assets or liabilities any rights and obligations created or retained in the transfer. If the entity has retained control, it must continue to recognise the financial asset to the extent of its continuing involvement in the financial asset (see section 5.3 below). [IFRS 9.3.2.6(c), IFRS 9.3.2.9].

Extract from IFRS 9

3.2.9 Whether the entity has retained control (see paragraph 3.2.6(c)) of the transferred asset depends on the transferee's ability to sell the asset. If the transferee has the practical ability to sell the asset in its entirety to an unrelated third party and is able to exercise that ability unilaterally and without needing to impose additional restrictions on the transfer, the entity has not retained control. In all other cases, the entity has retained control.

3.8.1 Transferee's 'practical ability' to sell the asset

IFRS 9 provides further guidance in two scenarios. Firstly, when a transferred asset is subject to a repurchase option, second, when a transfer imposes additional restrictions on selling the transferred assets. If a transferred asset is sold subject to an option that allows the entity to repurchase it, the transferee may (subject to the further considerations discussed below) have the practical ability to sell the asset if it can readily obtain the transferred asset in the market if the option is exercised. [IFRS 9.B3.2.7]. For this purpose, there has to be an active market for the asset.

The transferee has the practical ability to sell the transferred asset only if the transferee can sell the transferred asset in its entirety to an unrelated third party and is able to exercise that ability unilaterally and without imposing additional restrictions on the transfer. IFRS 9 requires that practical ability to sell the transferred asset be determined by considering what the transferee is able to do in practice, rather than solely by reference to any contractual rights or prohibitions. The standard notes that a contractual right to dispose of the transferred asset has little practical effect if there is no market for the transferred asset. [IFRS 9.B3.2.8(a)].

An ability to dispose of the transferred asset also has little practical effect if it cannot be exercised freely. Accordingly, the transferee's ability to dispose of the transferred asset must be a unilateral ability independent of the actions of others. In other words, the transferee must be able to dispose of the transferred asset without needing to attach conditions to the transfer (e.g., conditions about how a loan asset is serviced, or an option giving the transferee the right to repurchase the asset). [IFRS 9.B3.2.8(b)].

For example, the entity might sell a financial asset to a transferee, but the transferee has an option to put the asset back to the entity or has a performance guarantee from the entity. IFRS 9 argues that such an option or guarantee might be so valuable to the transferee that it would not, in practice, sell the transferred asset to a third party without attaching a similar option or other restrictive conditions. Instead, the transferee would hold the transferred asset so as to obtain payments under the guarantee or put option. Under these circumstances IFRS 9 regards the transferor as having retained control of the transferred asset. [IFRS 9.B3.2.9].

However, the fact that the transferee is simply unlikely to sell the transferred asset does not, of itself, mean that the transferor has retained control of the transferred asset. [IFRS 9.B3.2.9].

4 Practical application of the derecognition criteria

IFRS 9 gives a number of practical examples of the application of the derecognition criteria, which are discussed below.

In order to provide a link with Figure 3-1 in section 3.2 above we have used the following convention:

- 'Box 6, Yes' The transaction would result in the answer 'Yes' at Box 6 in Figure 3-1.
- 'Box 7, No' The transaction would result in the answer 'No' at Box 7 in Figure 3-1.

4.1 Repurchase agreements ('repos') and securities lending

4.1.1 Agreements to return the same asset

If a financial asset is:

- Sold under an agreement to repurchase it at a fixed price or at the sale price plus a lender's return
Or
- Loaned under an agreement to return it to the transferor

The asset is not derecognised, because the transferor retains substantially all the risks and rewards of ownership, [IFRS 9.B3.2.16(a)], (Figure 3-1, Box 7, Yes). The accounting treatment of such transactions is discussed in section 5.2 below.

4.1.1.A Transferee's right to pledge

If the transferee obtains the right to sell or pledge an asset that is the subject of such a transaction, the transferor reclassifies the asset on its statement of financial position as, for example, a loaned asset or repurchase receivable. [IFRS 9.B3.2.16(a)].

It appears that this accounting treatment is required merely where the transferee has the 'right' to sell or pledge the asset. This contrasts with the requirements for determining whether an asset subject to a transaction in which the entity neither transfers nor retains substantially all the risks and rewards associated with the asset (Figure 3-1, Box 7, No) nevertheless qualifies for derecognition because the transferee has control (Figure 3-1, Box 8, No). In order for the transferee to be regarded as having control for the purposes of Box 8, any rights of the transferee to sell an asset must have economic substance - see section 3.8.1 above.

The accounting treatment of such transactions is discussed in section 5.2 below.

4.1.2 Agreements with right to return the same or substantially the same asset

If a financial asset is:

- Sold under an agreement to repurchase the same or substantially the same asset at a fixed price or at the sale price plus a lender's return
Or
- Loaned under an agreement to return the same or substantially the same asset to the transferor

The asset is not derecognised because the transferor retains substantially all the risks and rewards of ownership, [IFRS 9.B3.2.16(b)], (Figure 3-1, Box 7, Yes). The accounting treatment of such transactions is discussed in section 5.2 below.

4.1.3 Agreements with right of substitution

If a financial asset is the subject of:

- A repurchase agreement at a fixed repurchase price or a price equal to the sale price plus a lender's return
Or
- A similar securities lending transaction

That provides the transferee with a right to substitute assets that are similar and of equal fair value to the transferred asset at the repurchase date, the asset sold or lent is not derecognised because the transferor retains substantially all the risks and rewards of ownership, [IFRS 9.B3.2.16(c)], (Figure 3-1, Box 7, Yes). The accounting treatment of such transactions is discussed in section 5.2 below.

4.1.4 Net cash-settled forward repurchase

IFRS 9 gives some guidance on the treatment of net cash-settled options over transferred assets (see section 4.2.5 below), which in passing refers to net cash-settled forward contracts. This guidance indicates that the key factor for determining whether derecognition is appropriate remains whether or not the entity has transferred substantially all the risks and rewards of the transferred asset. [IFRS 9.B3.2.16(k)]. This suggests that an asset sold subject to a fixed price net-settled forward contract to reacquire it must not be derecognised (see sections 4.1.1 to 4.1.3 above) until the forward contract is settled (Figure 3-1, Box 7, Yes). The accounting treatment of such transactions is discussed in section 5.2 below.

4.1.5 Agreement to repurchase at fair value

A transfer of a financial asset subject only to a forward repurchase agreement with a repurchase price equal to the fair value of the financial asset at the time of repurchase results in derecognition because of the transfer of substantially all the risks and rewards of ownership, [IFRS 9.B3.2.16(j)], (Figure 3-1, Box 6, Yes). The accounting treatment of such transactions is discussed in section 5.1 below.

4.1.6 Right of first refusal to repurchase at fair value

If an entity sells a financial asset and retains only a right of first refusal to repurchase the transferred asset at fair value if the transferee subsequently sells it, the entity derecognises the asset because it has transferred substantially all the risks and rewards of ownership, [IFRS 9.B3.2.16(d)], (Figure 3-1, Box 6, Yes).

IFRS 9 does not address the treatment of a financial asset sold with a right of first refusal to repurchase the transferred asset at a predetermined value that might well be lower or higher than fair value (e.g., an amount estimated, at the time at which the original transaction was entered into, as the future market value of the asset). One analysis might be that, since the transferee is under no obligation to put the asset up for sale, derecognition is still appropriate. Another analysis might be that, if the asset can ultimately only be realised by onward sale, the arrangement is nearer in substance to a transferor's call option (see section 4.2 below).

4.1.7 Wash sale

A 'wash sale' is the repurchase of a financial asset shortly after it has been sold. Such a repurchase does not preclude derecognition provided that the original transaction met the derecognition requirements. However, if an agreement to sell a financial asset is entered into concurrently with an agreement to repurchase the same asset at a fixed price or the sale price plus a lender's return, then the asset is not derecognised. [IFRS 9.B3.2.16(e)]. Such a transaction would be equivalent to those in sections 4.1.1 to 4.1.4 above.

4.2 Transfers subject to put and call options

An option contract is a contract which gives one party to the contract the right, but not the obligation, to buy from, or sell to, the other party to the contract the asset that is the subject of the contract for a given price (often, but not always, a price that is fixed) at a future date (or during a longer period ending on a future date). An option giving the right to buy an asset is referred to as a 'call' option and one giving the right to sell as a 'put' option. An option is referred to as a 'bought' or 'purchased' option from the perspective of the party with the right to buy or sell (the 'holder') and as a 'written' option from the perspective of the party with the potential obligation to buy or sell. An option is referred to as 'in the money' when it would be in the holder's interest to exercise it and as 'out of the money' when it would not be in the holder's interest to exercise it.

Under IFRS 9 an option is:

- 'Deeply in the money' when it is so far in the money that it is highly unlikely to go out of the money before expiry [IFRS 9.B3.2.5(d)]
- And
- 'Deeply out of the money' when it is so far out of the money that it is highly unlikely to become in the money before expiry [IFRS 9.B3.2.4(c)]

IFRS 9 does not elaborate on what it means by 'highly unlikely' in this context, although the Implementation Guidance to IAS 39 clarified that 'highly probable' (in the context of a 'highly probable forecast transaction' subject to a hedge) indicates a much greater likelihood of happening than the term 'more likely than not'. [IAS 39.F.3.7].

4.2.1 Deeply in the money put and call options

If a transferred financial asset can be called back by the transferor, and the call option is deeply in the money, the transfer does not qualify for derecognition because the transferor has retained substantially all the risks and rewards of ownership (Figure 3-1, Box 7, Yes).

Similarly, if the financial asset can be put back by the transferee, and the put option is deeply in the money, the transfer does not qualify for derecognition because the transferor has retained substantially all the risks and rewards of ownership, [IFRS 9.B3.2.16(f)], (Figure 3-1, Box 7, Yes).

The accounting treatment for such transactions would be similar to that for 'repos' as set out in Illustration 5-5 in section 5.2 below.

If a transferred asset continues to be recognised because of a transferor's call option or transferee's put option, but the option subsequently lapses unexercised, the asset and any associated liability would then be derecognised.

4.2.2 Deeply out of the money put and call options

A financial asset that is transferred subject only to a transferee's deeply out of the money put option, or a transferor's deeply out of the money call option, is derecognised. This is because the transferor has transferred substantially all the risks and rewards of ownership, [IFRS 9.B3.2.16(g)], (Figure 3-1, Box 6, Yes).

4.2.3 Options that are neither deeply out of the money nor deeply in the money

Where a financial asset is transferred subject to an option (whether a transferor's call option or a transferee's put option) that is neither deeply in the money nor deeply out of the money, the result is that the entity neither transfers nor retains substantially all the risks and rewards associated with the asset, [IFRS 9.B3.2.16(h), IFRS 9.B3.2.16(i)], (Figure 3-1, Box 7, No). It is therefore necessary to determine whether or not the transferor has retained control of the asset under the criteria summarised in section 3.8 above.

If a transferred asset continues to be recognised because of a transferor's call option or transferee's put option, but the option subsequently lapses unexercised, the asset and any associated liability would then be derecognised.

4.2.3.A Assets readily obtainable in the market

If the transferor has a call option over a transferred financial asset that is readily obtainable in the market, IFRS 9 considers that control of the asset has passed to the transferee (Figure 3-1, Box 8, No - see section 3.8 above). [IFRS 9.B3.2.16(h)]. This would presumably also be the conclusion where the transferee has a put option over a transferred financial asset that is readily obtainable in the market, although IFRS 9 does not specifically address this.

4.2.3.B Assets not readily obtainable in the market

If the transferor has a call option over a transferred financial asset that is not readily obtainable in the market, IFRS 9 considers that control of the asset remains with the transferor (Figure 3-1, Box 8, Yes - see section 3.8 above). Accordingly, derecognition is precluded to the extent of the amount of the asset that is subject to the call option. [IFRS 9.B3.2.16(h)].

If the transferee has a put option over a transferred financial asset that is not readily obtainable in the market, IFRS 9 requires the transferee's likely economic behaviour to be assessed - in effect to determine whether the option gives the transferee the practical ability to sell the transferred asset (see section 3.8.1 above).

If the put option is sufficiently valuable to prevent the transferee from selling the asset, the transferor is considered to retain control of the asset and continues to account for the asset to the extent of its continuing involvement, [IFRS 9.B3.2.16(i)], (Figure 3-1, Box 9). The accounting treatment required is discussed in section 5.3 below.

If the put option is not sufficiently valuable to prevent the transferee from selling the asset, the transferor is considered to have ceded control of the asset, and will derecognise it, [IFRS 9.B3.2.16(i)], (Figure 3-1, Box 8, No).

The question of whether or not a put option is sufficiently valuable to prevent the transferee from selling the asset is not a matter of objective fact, but rather a function of the transferee's appetite for risk, its need for liquidity and so forth. It is not clear how the transferor can readily assess these factors.

4.2.4 Option to put or call at fair value

A transfer of a financial asset subject only to a put or call option with an exercise price equal to the fair value of the financial asset at the time of repurchase results in derecognition because of the transfer of substantially all the risks and rewards of ownership (Figure 3-1, Box 6, Yes). [IFRS 9.B3.2.16(j)].

4.2.5 Net cash-settled options

Where a transfer of a financial asset is subject to a put or call option that will be settled net in cash, IFRS 9 requires the entity to evaluate the transfer so as to determine whether it has retained or transferred substantially all the risks and rewards of ownership. [IFRS 9.B3.2.16(k)]. IFRS 9 comments that “if the entity has not retained substantially all the risks and rewards of ownership of the transferred asset, it determines whether it has retained control of the transferred asset” - a repetition of the basic principles of the standard adding no clarification specific to this type of transaction.

However, net-cash settlement means that it is more likely that control has passed, as the transferee would not need to hold the assets in case the options are exercised.

4.2.6 Removal of accounts provision

A ‘removal of accounts provision’ is an unconditional repurchase (i.e., call) option that gives an entity the right to reclaim transferred assets subject to some restrictions. Provided that such an option results in the entity neither retaining nor transferring substantially all the risks and rewards of ownership, IFRS 9 allows derecognition, except to the extent of the amount subject to repurchase (assuming that the transferee cannot sell the assets).

For example, if an entity transfers loan receivables with a carrying amount of CU100,000 for proceeds of CU100,000, subject only to the right to call back any individual loan(s) up to a maximum of CU10,000, CU90,000 of the loans would qualify for derecognition. [IFRS 9.B3.2.16(l)].

4.2.7 Clean-up call options

A ‘clean-up call’ option is an option held by an entity that services transferred assets (and may be the transferor of those assets) to purchase remaining transferred assets when the cost of servicing the assets exceeds the entity’s participation in their benefits. If such a clean-up call results in the entity neither retaining nor transferring substantially all the risks and rewards of ownership, and the transferee cannot sell the assets, IFRS 9 precludes derecognition only to the extent of the amount of assets subject to the call option. [IFRS 9.B3.2.16(m)].

4.2.8 Same (or nearly the same) price put and call options

IFRS 9 does not specifically address the transfer of an asset subject to both a transferee’s option to put, and a transferor’s option to call, the asset at a fixed price rather than at fair value (as discussed in section 4.2.4 above). Assuming that:

- Both options can be exercised simultaneously
- And
- Both the transferor and transferee behave rationally

It will clearly be in the interest of either the transferor or the transferee to exercise its option, so that the asset will be reacquired by the transferor. This indicates that the transferor has retained substantially all the risks and rewards of ownership.

However, if the two options were exercisable on different dates or at different prices, the effects of each option would need to be considered carefully.

4.2.9 Changes in probability of exercise of options after initial transfer of asset

IFRS 9 is not explicit as to the accounting consequences (if any) of an option that was considered at the time of the original transfer to be deeply out of the money subsequently becoming neither deeply in the money nor deeply out of the money, or even deeply in the money, (or any other of the possible permutations). This is explored further in Illustration 4-1 to Illustration 4-3 below.

Illustration 4-1: Financial asset transferred subject only to deeply out of the money call option

On 1 January 20X0 an entity transferred a financial asset to a counterparty, subject only to a call option to repurchase the asset at any time up to 31 December 20X4. At 1 January 20X0 the option was considered deeply out of the money and the asset was accordingly derecognised (see section 4.2.2 above).

At 31 December 20X3 market conditions have changed considerably and the option is now deeply in the money. What is the accounting consequence of this change?

There are no accounting consequences since, as noted in section 3.7 above, IFRS 9.B3.2.6 specifies that an asset previously derecognised because substantially all the risks and rewards associated with the asset have been transferred (as would be the analysis for an asset transferred subject only to a deeply out of the money call - see section 4.2.2 above) is not re-recognised in a future period unless it is reacquired. [IFRS 9.B3.2.6]. Instead, the increase in the fair value of the option would be captured in the financial statements as a gain under the normal requirement of IFRS 9 to account for derivatives at fair value with changes in value reflected in profit or loss (see Chapter 44).

However, if the market changes were not demonstrably beyond any reasonable expectation as at 1 January 20X0 there might be an argument (given the definition of a deeply out of the money option as an option that is 'highly unlikely' to become in the money before expiry - see section 4.2 above) that the fact that the option is now not merely in the money, but deeply in the money, indicates that the original assessment that that option was deeply out of the money was in fact an accounting error requiring correction under IAS 8 (see Chapter 3).

Illustration 4-2: Financial asset transferred subject only to deeply in the money call option

On 1 January 20X0 an entity transferred a financial asset to a counterparty, subject only to a call option to repurchase the asset at any time up to 31 December 20X4. At 1 January 20X0 the option was considered deeply in the money and the asset was accordingly not derecognised (see section 4.2.1 above).

At 31 December 20X3 market conditions have changed considerably and the option is now deeply out of the money. What is the accounting consequence of this change?

This is the mirror image of the fact pattern in Illustration 4-1. However, whereas IFRS 9 makes it clear that an asset previously derecognised is not re-recognised, there is no comparable provision that an asset that previously did not qualify for derecognition on the origination of a particular transaction may not later be derecognised as a result of a subsequent change in the assessed likely impact of the transaction. Because the standard does not explain the consequences, it is not clear when the asset can be derecognised subsequent to a sale transaction or whether there is any basis for derecognising the asset before the expiry of the option.

Assuming the asset in Illustration 4-2 above is not derecognised, the fall in the value of the option indicates a decline in the fair value of the asset which is likely to be required to be reflected in the financial statements under the normal requirements of IFRS 9. This would in turn appear to require a corresponding adjustment to the liability recognised for the sale proceeds, so as to avoid recognising a net loss in the income statement that has not actually been suffered.

Illustration 4-3: Financial asset transferred subject to call option neither deeply in the money nor deeply out of the money

On 1 January 20X0 an entity transferred a financial asset (an equity share) to a counterparty, subject only to a call option to repurchase the asset at any time up to 31 December 20X4. At 1 January 20X0 the option was considered to be neither deeply in the money nor deeply out of the money. However, the asset was readily marketable and freely transferable by the transferor and was accordingly derecognised because the entity, while neither transferring nor retaining substantially all the risks and rewards of the asset, no longer controls it (see section 4.2.3.A above).

At 31 December 20X3 the financial asset that was the subject of the transfer ceases to be listed and is therefore not readily marketable. Had this been the case at the time of the original transfer, the entity would have been regarded as retaining control of the asset, which would not have been derecognised (see section 4.2.3.B above). What is the accounting consequence of this change?

Again, matters are not entirely clear. The rule in IFRS 9.B3.2.6 that a previously derecognised asset will not be re-recognised (other than on reacquisition of the asset) applies, as drafted, only where derecognition results from a transfer of substantially all the risks and rewards associated with the asset. In this case, derecognition has resulted from a loss of control over, not a transfer of substantially all the risks and rewards associated with, the asset. There is therefore some ambiguity as to whether B3.2.6 is to be read:

- Generally as prohibiting any re-recognition of a derecognised asset
- Or
- Specifically as referring only to circumstances where derecognition results from transfer of substantially all the risks and rewards (i.e., it applies only to 'Box 6, Yes' transactions, and not to 'Box 8, No' transactions)

How we see it

We expect that the original decision to derecognise the asset will not be revisited, unless (in exceptional circumstances) the original assessment was an accounting error within the scope of IAS 8. The fact that the asset was transferred on terms that the transferee could freely dispose of the asset means that the transferor did indeed lose control at the time of the transaction.

4.3 Subordinated retained interests and credit guarantees

Where a financial asset is transferred, an entity may provide the transferee with credit enhancement by subordinating some or all of its interest retained in the transferred asset. Alternatively, an entity may provide the transferee with credit enhancement in the form of a credit guarantee that could be unlimited or limited to a specified amount. [IFRS 9.B3.2.16(n)]. Such techniques are commonly used in securitisation transactions (see section 3.3 above).

IFRS 9 notes that, if the entity retains substantially all the risks and rewards of ownership of the transferred asset, the asset continues to be recognised in its entirety. If the entity retains some, but not substantially all, of the risks and rewards of ownership and has retained control, derecognition is precluded to the extent of the amount of cash or other assets that the entity could be required to pay. [IFRS 9.B3.2.16(n)].

4.4 Transfers involving swaps

4.4.1 Total return swaps

An entity may sell a financial asset to a transferee and enter into a total return swap with the transferee, whereby the transferor pays an amount equivalent to fixed or floating rate interest on the consideration for the transfer and receives an amount equivalent to the cash flows from, together with any increases or decreases in the fair value of, the underlying asset. In such a case, derecognition of all of the asset is prohibited, [IFRS 9.B3.2.16(o)], since the transaction has the effect that substantially all the risks and rewards associated with the asset are retained by the transferor (Figure 3-1, Box 7, Yes).

4.4.2 Interest rate swaps

An entity may transfer a fixed rate financial asset and enter into an interest rate swap with the transferee to receive a fixed interest rate and pay a variable interest rate based on a notional amount equal to the principal amount of the transferred financial asset. IFRS 9 states that the interest rate swap does not preclude derecognition of the transferred asset, provided that the payments on the swap are not conditional on payments being made on the transferred asset. [IFRS 9.B3.2.16(p)].

If, however, the transferor were to transfer an asset subject to prepayment risk (e.g., a domestic mortgage), and the transferor and transferee were to enter into an amortising interest rate swap (i.e., one whose notional amount amortises so that it equals the principal amount of the transferred financial asset outstanding at any point in time), the transferor would generally retain substantial prepayment risk through the swap. In this case, the transferor would (depending on the other facts of the transaction, such as the transfer or retention of credit risk) continue to recognise the transferred asset either in its entirety (Figure 3-1, Box 7, Yes) or to the extent of the transferor's continuing involvement (Figure 3-1, Box 9). [IFRS 9.B3.2.16(q)].

Conversely, if the transferor and the transferee were to enter into an amortising interest rate swap, the amortisation of the notional amount of which is not linked to the principal amount outstanding on the transferred asset, the transferor would no longer retain prepayment risk. Therefore such a swap would not preclude derecognition of the transferred asset, provided the payments on the swap were not conditional on interest payments being made on the transferred asset and the swap did not result in the entity retaining any other significant risks and rewards of ownership on the transferred asset. [IFRS 9.B3.2.16(q)].

4.5 Factoring of trade receivables

IFRS 9 does not specifically address one of the more common forms of 'off-balance sheet finance' - the factoring of trade receivables. The common aim of all factoring structures is to provide cash flow from trade receivables quicker than would arise from normal cash collections, which is generally achieved by a 'sale' of all, or certain selected, receivables to a financial institution. However, the conditions of such 'sales' are extremely varied (which may well explain the lack of any generic guidance in the standard), ranging from true outright sales and pass-through arrangements (resulting in full derecognition), to transactions with continuing involvement through guarantee or subordination arrangements. It will therefore be necessary for an entity to consider the terms of its particular debt-factoring arrangement(s) carefully in order to determine the appropriate application of the derecognition provisions of IFRS 9, particularly those discussed in sections 3.5 and 3.7 above.

Depending on circumstances, Illustration 5-1 (see section 5.1 below), Illustration 5-2 (see section 5.1.1 below), Illustration 5-6 (see section 5.4.1 below) and Illustration 5-12 (see section 5.4.4 below) may also be of particular relevance.

5 Accounting treatment

This part of the chapter deals with the accounting consequences of the derecognition criteria for financial assets - in other words how the principles discussed above translate into accounting entries.

In order to provide a link with Figure 3-1 in section 3.2 above we have used the following convention:

- 'Box 6, Yes' The transaction would result in the answer 'Yes' at Box 6 in Figure 3-1.
 'Box 7, No' The transaction would result in the answer 'No' at Box 7 in Figure 3-1.

5.1 Transfers that qualify for derecognition

It is important to remember throughout this section that references to an asset being derecognised in its entirety include situations where a part of an asset to which the derecognition criteria are applied separately is derecognised in its entirety (see section 3.4 above). In this context, IFRS 9 uses the phrase 'in its entirety' in contrast to the accounting treatment applied to assets where there is continuing involvement (see section 5.3 below) where some, but not all, of a financial asset, or part of an asset, is derecognised.

If, as a result of a transfer, a financial asset is derecognised in its entirety but the transfer results in the transferor obtaining a new financial asset or servicing asset or assuming a new financial liability, or a servicing liability (see section 5.1.2 below), IFRS 9 requires the entity to recognise the new financial asset, servicing asset, financial liability or servicing liability at fair value. [IFRS 9.3.2.11].

On derecognition of a financial asset in its entirety, IFRS 9 requires the difference between:

- (a) The carrying amount of the asset
 And
 (b) The consideration received (including any new asset obtained less any new liability assumed)

To be recognised in profit or loss. [IFRS 9.3.2.12]. In addition, any cumulative gain or loss in respect of that asset which was previously recognised in other comprehensive income shall be reclassified from equity to profit or loss if the asset is a debt instrument accounted for at fair value through other comprehensive income under IFRS 9. [IFRS 9.5.7.10].

Illustration 5-1 illustrates these requirements.

Illustration 5-1: Derecognition of whole of financial asset in its entirety

At 1 October 20X2 an entity has a debt instrument classified at fair value through other comprehensive income, carried at CU1,400, in respect of which a cumulative gain of CU200 has been recognised in equity. At that date, the asset is unconditionally sold to a third party in exchange for cash of CU2,500 and a loan note issued to the third party. The loan note bears a fixed rate interest below current market rates and is repayable at CU1,150 but is considered to have a fair value of CU1,100. The following accounting entries are made by the entity to record the disposal:

	CU	CU
Dr Cash	2,500	
Dr Equity ('recycling' of cumulative gain on asset)	200	
Cr Gain on disposal		200
Cr Asset		1,400
Cr Loan note		1,100

Thereafter the loan note will be accreted up to its repayable amount of CU1,150 over its expected life using the effective interest method (see Chapter 46).

If the asset had been accounted for using the amortised cost method and had a carrying amount of (say) CU1,200 at the date of the transfer, the accounting entry would have been:

	CU	CU
Dr Cash	2,500	
Cr Profit on disposal		200
Cr Asset		1,200
Cr Loan note		1,100

For simplicity, the calculations above ignore the release of the expected credit loss provision.

5.1.1 Transferred asset part of a larger asset

If the transferred asset is part of a larger financial asset, for example when an entity transfers interest cash flows that are part of a debt instrument (see section 3.4 above), and the part transferred qualifies for derecognition in its entirety, IFRS 9 requires the previous carrying amount of the larger financial asset to be allocated between the part that continues to be recognised and the part that is derecognised. The allocation is based on the relative fair values of those parts on the date of the transfer. For this purpose, the retained servicing asset (see section 5.1.2 below) is to be treated as a part that continues to be recognised.

IFRS 9 requires the difference between:

- (a) The carrying amount allocated to the part derecognised

And

- (b) The sum of:

- (i) The consideration received for the part derecognised (including any new asset obtained less any new liability assumed)

And

- (ii) Any cumulative gain or loss allocated to it previously recognised directly in equity

To be recognised in profit or loss. Any cumulative gain or loss that had been recognised in equity is allocated between the part that continues to be recognised and the part that is derecognised, based on the relative fair values of those parts. [IFRS 9.3.2.13].

The requirement in (b)(ii) above for 'recycling' of any cumulative gain or loss previously recognised directly in equity applies to debt instruments accounted for at fair value through other comprehensive income under IFRS 9.

IFRS 9 notes that the accounting treatment prescribed for the derecognition of a part (or parts) of a financial asset requires an entity to determine the fair value of the part(s) that continue to be recognised. Where the entity has a history of selling parts similar to the part that continues to be recognised, or other market transactions exist for such parts, IFRS 9 requires recent prices of actual transactions to be used to provide the best estimate of its fair value. When there are no price quotations or recent market transactions to support the fair value of the part that continues to be recognised, the best estimate of the fair value is the difference between:

- The fair value of the larger financial asset as a whole

And

- The consideration received from the transferee for the part that is derecognised [IFRS 9.3.2.14]

When measuring the fair values of the part that continues to be recognised and the part that is derecognised, in addition to the guidance above, an entity applies the fair value measurement requirements in IFRS 13 (see Chapter 15). [IFRS 9.B3.2.11].

Illustration 5-2 illustrates the requirements for full derecognition of a part of an asset.

Illustration 5-2: Derecognition of part of financial asset in its entirety

On 1 January 20X0 an entity invested CU1 million in a loan with a par value of CU1 million. The loan pays interest of CU75,000 on 31 December annually in arrears and is to be redeemed at par on 31 December 20X8. The entity accounts for the loan at amortised cost.

On 1 January 20X4 it unconditionally sells the right to receive the remaining five interest payments to a bank. The derecognition provisions of IFRS 9 are applied to the interest payments as an identifiable part of the asset (see section 3.4 above), leading to the conclusion that they are required to be derecognised.

The consideration received for, and the fair value of, the future interest payments (based on the net present value, as at 1 January 20X4, of the payments at the current market interest rate that would be available to the borrower of 5%) is CU324,711 ($CU75,000 \div 1.05 + CU75,000 \div 1.05^2 \dots + CU75,000 \div 1.05^5$). By the same methodology the fair value of the principal repayment can be calculated as CU783,526 ($CU1,000,000 \div 1.05^5$), giving a total fair value for the loan of CU1,108,237.

In order to calculate the gain or loss on disposal, the total carrying value of the loan of CU1,000,000 is allocated between the part disposed of and the part retained, based on the fair values of those parts. This allocates CU292,998 ($CU1,000,000 \times CU324,711 \div CU1,108,237$) to the interest payments disposed of and CU707,002 ($CU1,000,000 \times CU783,526 \div CU1,108,237$) to the retained right to the repayment of principal. This generates the accounting entry:

		CU	CU
Dr	Cash	324,711	
	Cr Loan (portion of carrying amount allocated to interest payments)		292,998
	Cr Gain on disposal		31,713

If the loan had instead been a bond accounted for at fair value through other comprehensive income, it would already have been carried at CU1,108,237, so that the basic disposal journal would simply be:

		CU	CU
Dr	Cash	324,711	
	Cr Bond (portion of carrying amount allocated to interest payments)		324,711

However, as the bond was accounted for at fair value through other comprehensive income, it would also be necessary to recycle that portion of the cumulative revaluation gain of CU108,237 that relates to the interest 'component' of the total carrying value from equity to the income statement. IFRS 9 requires a *pro rata* allocation of the cumulative gain or loss in equity based on the total fair value of the interest and principal - this would deem CU31,713 ($CU108,237 \times CU324,711 \div CU1,108,237$) of the cumulative revaluation gain to relate to interest. This would give rise to the further journal, resulting in the same gain on disposal as above:

		CU	CU
Dr	Equity	31,713	
	Cr Gain on disposal (income statement)		31,713

For simplicity, the calculations above ignore the impact of the expected credit losses on the cumulative revaluation gain.

5.1.2 Servicing assets and liabilities

It is common for an entity to transfer a financial asset (or part of a financial asset) in its entirety, but to retain the right or obligation to service the asset, i.e., to collect payments as they fall due and undertake other administrative tasks, in return for a fee.

When an entity transfers a financial asset in a transfer that qualifies for derecognition in its entirety and retains the right to service the financial asset for a fee, IFRS 9 requires the entity to recognise either a servicing asset or a servicing liability for that servicing contract, as follows:

- If the fee to be received is not expected to compensate the entity adequately for performing the servicing, the entity shall recognise a servicing liability for the servicing obligation at its fair value.
- If the fee to be received is expected to be more than adequate compensation for the servicing, the entity shall recognise a servicing asset for the servicing right. This shall be recognised at an amount determined on the basis of an allocation of the carrying amount of the larger financial asset (as described in section 5.1.1 above). [IFRS 9.3.2.10].

It is not immediately clear what is meant by this requirement. The application guidance expands on the point, as follows.

An entity may retain the right to a part of the interest payments on transferred assets as compensation for servicing those assets. The part of the interest payments that the entity would give up upon termination or transfer of the servicing contract is allocated to the servicing asset or servicing liability. The part of the interest payments that the entity would not give up is an interest-only strip receivable.

For example, if the entity would not give up any interest upon termination or transfer of the servicing contract, the entire interest spread is an interest-only strip receivable. Presumably, as the entity will still have a liability to service the portfolio, it will have to account for this if it allocates none of the interest spread as compensation for the servicing. For the purposes of applying the requirements for disposals of part of an asset discussed in section 5.1.1 above, the fair values of the servicing and interest-only strip receivable are used to allocate the carrying amount of the receivable between the part of the asset that is derecognised and the part that continues to be recognised. If there is no servicing fee specified, or the fee to be received is not expected to compensate the entity adequately for performing the servicing, a liability for the servicing obligation is recognised at fair value. [IFRS 9.B3.2.10].

Unfortunately, IFRS 9 does not provide examples of what exactly is meant here, but we believe that something along the lines of Illustration 5-3 below was intended.

Illustration 5-3: Servicing assets and liabilities

An entity has a portfolio of originated domestic mortgages which are accounted for at amortised cost and have a carrying amount of CU10 million. The mortgages bear interest at a fixed rate of 7.5%. The average life of the mortgages in the portfolio (taking account of prepayment risk) is 12 years and the fair value of the serviced portfolio is CU11 million, representing CU4.5 million in respect of future interest payments and CU6.5 million in respect of the principal amounts. The entity assesses the amount that would compensate it for servicing the assets to be CU0.5 million.

The entity sells the entire portfolio to a bank (on terms such that it qualifies for derecognition under IFRS 9) but continues to service the portfolio. If the entity does not retain any part of the interest payments, the selling price would be the fair value of the assets of CU11 million (or very close to it). It would then assume a servicing liability of CU0.5 million, giving rise to the accounting entry:

		CU m	CU m
Dr	Cash	11.0	
	Cr Mortgage portfolio		10.0
	Cr Servicing liability		0.50
	Cr Profit on disposal		0.50

Alternatively, it retains interest payments of 1% and the right to service the portfolio. The entity would not give up any interest upon termination or transfer of the servicing contract. The entity estimates that the fair value of the right to receive interest payments of 1% is CU0.6 million. In this case, the bank would be expected to pay fair value of CU10.4 million (or very close to it).

The standard states - see above - that, if (as is the case here) the entity would not give up any interest on termination or transfer of the contract, then the whole of the interest spread is an interest-only strip receivable. In order to calculate the amount of the portfolio to be derecognised, the carrying value of CU10 million is pro-rated (as in Illustration 5-2 in section 5.1.1 above) as to CU9.45 million disposed of ($\text{CU}10\text{m} \times 10.4 \div 11$) and the part retained of CU0.55 million ($\text{CU}10\text{m} \times 0.6 \div 11$). However, as it has allocated the full amount of the interest spread to an interest-only strip receivable, it would need to recognise a servicing liability of CU0.5 million in respect of its obligations under the contract. This gives rise to the following accounting entry:

		CU m	CU m
Dr	Cash	10.40	
Dr	Interest-only strip receivable	0.55	
	Cr Mortgage portfolio (CU9.45 million disposed of plus CU0.55 million reclassified as interest-only strip receivable)		10.00
	Cr Servicing liability		0.50
	Cr Profit on disposal		0.45

If the entity were to retain only a portion of the interest spread on termination or transfer of the servicing contract equivalent to CU0.1 million out of the total retained interest spread of CU0.55 million, then IFRS 9 requires - see above:

- The part of the interest payments that the entity would not give up, i.e., the part which is not contingent on fulfilment of the servicing obligation (CU0.1 million) to be treated as an interest-only strip receivable. And
- The part of the interest payments that the entity would give up (i.e., CU0.45 million calculated as CU0.55 million of total retained interest spread less CU0.1 million in previous bullet) upon termination or transfer of the servicing contract to be allocated to the servicing asset or servicing liability.

This suggests that the following accounting entry would be made:

		CU m	CU m
Dr	Cash	10.40	
Dr	Interest-only strip receivable	0.10	
	Cr Mortgage portfolio (CU9.45 million disposed of plus CU0.1m reclassified as interest-only strip receivable and CU0.45 million allocated to servicing liability)		10.00
	Cr Servicing liability (CU0.50 million gross fair value less interest payments that would be lost on termination or transfer - CU0.45 million)		0.05
	Cr Profit on disposal		0.45

A servicing asset is a non-financial asset representing a right to receive a higher than normal amount for performing future services. Accordingly, it would normally be accounted for in accordance with IAS 38 *Intangible Assets*. Similarly, a servicing liability represents consideration received in advance for services to be performed in the future and would normally be accounted for as deferred revenue in accordance with IFRS 15.

5.2 Transfers that do not qualify for derecognition through retention of risks and rewards

If a transfer does not result in derecognition because the entity has retained substantially all the risks and rewards of ownership of the transferred asset (see section 3.7 above), IFRS 9 requires the entity to continue to recognise the transferred asset in its entirety and recognise a financial liability for any consideration received. In subsequent periods, the entity recognises any income on the transferred asset and any expense incurred on the financial liability. [IFRS 9.3.2.15]. This treatment is illustrated by Illustration 5-4 and Illustration 5-5 below.

It should be noted that these provisions apply only where derecognition does not occur as a result of retention by the transferor of substantially all the risks and rewards of ownership of the transferred asset (Figure 3-1, Box 7, Yes). They do not apply where derecognition does not occur as a result of continuing involvement in an asset of which substantially all the risks and rewards of ownership are neither retained nor transferred (Figure 3-1, Box 8, Yes). Such transactions are dealt with by the separate provisions discussed in sections 5.3 and 5.4 below.

Illustration 5-4: Asset not qualifying for derecognition (risks and rewards retained)

An entity holds a loan of CU1,000 made on 1 January 20X0, paying interest of CU65 annually in arrears and redeemable at par on 31 December 20X4, which it accounts for at amortised cost (see Chapter 46).

On 1 January 20X4 it enters into a transaction whereby the loan is sold to a bank for its then fair value of CU985, but with full recourse to the entity for any default on the loan. The guarantee provided by the entity has the effect that it retains substantially all the risks and rewards of the loan, which is therefore not derecognised (Figure 3-1, Box 7, Yes - see section 3.7.2 above). [IFRS 9.B3.2.12].

The entity therefore continues to recognise the loan, and interest on it, as if it still held the loan. It accounts for the CU985 proceeds as a liability which must be accreted up using the effective interest method (see Chapter 46) so that it will be equal to the carrying amount of the asset on the date on which it is expected that the asset will be derecognised.

In this case, the asset will be derecognised at maturity on 31 December 20X4 when a payment of CU1,065 (the final instalment of interest of CU65 and return of principal of CU1,000) is due. Accordingly, the liability must be accreted from CU985 to CU1,065 during the year ended 31 December 20X4. The following accounting entries are made by the entity:

1 January 20X4

	CU	CU
Dr Cash	985	
Cr Liability		985

Consideration received from bank

1 January-31 December 20X4

	CU	CU
Dr Loan (CU1,065 at 31.12.20X4 - CU1,000 at 1.1.20X4)	65	
Dr Interest on liability (income statement)	80	
Cr Interest on loan (income statement)		65
Cr Liability (CU1,065 at 31.12.20X4 - CU985 at 1.1.20X4)		80

Accretion of interest income on the loan and interest expense on the liability

31 December 20X4

	CU	CU
Dr Liability	1,065	
Cr Loan receivable		1,065

'Redemption' of loan and 'discharge' of liability

This accounting treatment recognises an overall loss of CU15 in 20X4, which would be expected, as representing the difference between the carrying value of the asset at the date of transfer (CU1,000) and the consideration received (CU985). However, IFRS 9 requires the various elements of the transaction to be shown separately - it would not have been acceptable for the income statement simply to show a net loss of CU15.

If the transferred asset had been accounted for at fair value through profit or loss, it would already have been carried at CU985 at the date of transfer - i.e., the loss of CU15 would already have been reflected in the financial statements. The accounting entries at 1 January and 31 December 20X4 would be the same as above. However, the following accounting entries would then have been made during the year ended 31 December 20X4:

1 January-31 December 20X4

	CU	CU
Dr Interest on liability (income statement)	80	
Dr Loan (CU1,065 at 31.12. 20X4 - CU985 at 1.1.20X4)	80	
Cr Liability (CU1,065 at 31.12. 20X4 - CU985 at 1.1.20X4)		80
Cr Interest on loan (income statement)*		65
Cr Change in fair value of loan (income statement)*		15

Recognition of interest on, and change in fair value of, loan and accretion of interest on liability

* There is no IAS 1 *Presentation of Financial Statements* requirement to show the interest accrual and fair value gains and losses for this instrument separately.

Whilst the total amounts recorded in the income statement net to nil, they are arrived at by different methodologies - the CU80 increase in the carrying value of the loan receivable is recognised as the fair value changes whereas the CU80 interest on the liability is accrued at a constant effective interest rate. This means that, if the entity were to prepare financial statements at an interim date, it might well show a net gain or loss on the transaction at that date, notwithstanding that ultimately no gain or loss will be reflected.

Illustration 5-5: Asset not qualifying for derecognition ('repo' transaction)

An entity holds a government bond of CU2,000 issued on 1 January 20X0, paying interest of CU50 semi-annually in arrears and redeemable at par on 31 December 20X5, which it accounts for as a financial asset subsequently measured at amortised cost.

A Gross-settled transaction

On 1 January 20X4 the entity enters into a transaction whereby the bond is sold to a bank for its then fair value of CU1,800, and the entity agrees to repurchase it on 1 January 20X5 for CU1,844. As the legal owner of the loan at 30 June 20X4 and 31 December 20X4, the bank will receive the CU100 interest payable on the bond for the calendar year 20X4. This CU100, together with the CU44 difference between the sale and repurchase price gives the bank CU144, representing a lender's return of 8% on the CU1,800 sale proceeds. Accordingly, the effect of the transaction is that the entity has retained substantially all the risks and rewards of ownership of the bond (Figure 3-1, Box 7, Yes - see section 4.1 above).

The entity therefore continues to recognise the bond, and interest on it, as if it still held the bond. It accounts for the CU1,800 proceeds as a liability which must be accreted up to CU1,944 (the repurchase price due on 31 December 20X4 plus the interest on bonds collected by the bank) over the period to 31 December 20X4 using the effective interest method (see Chapter 46). The following accounting entries are made by the entity:

1 January 20X4

	CU	CU
Dr Cash	1,800	
Cr Liability		1,800

Consideration received from bank

1 January-31 December 20X4

	CU	CU
Dr Interest on liability (income statement)	144	
Dr Bond (CU2,100 at 31.12.20X4 - CU2,000 at 1.1.20X4)	100	
Cr Liability (CU1,944 at 31.12.20X4 - CU1,800 at 1.1.20X4)		144
Cr Interest on bond (income statement)		100

Accretion of income on bond and finance cost of liability

1 January-31 December 20X4

	CU	CU
Dr Liability	100	
Cr Bond		100

Notional receipt of interest on bond at 30 June and 31 December and notional transfer thereof to bank

1 January 20X5

	CU	CU
Dr Liability	1,844	
Cr Cash		1,844

Execution of repurchase contract

The above is arguably the strict translation into accounting entries of the accounting analysis under IFRS 9 for a situation where the entity still retains ownership of the bond throughout 20X4. As a matter of practicality, however, the same overall result could have been obtained by the following 'short-cut' approach, which avoids recording the notional receipt and transfer to the bank of bond interest received on 30 June and 31 December:

1 January 20X4

	CU	CU
Dr Cash	1,800	
Cr Liability		1,800

Consideration received from bank

1 January-31 December 20X4

	CU	CU
Dr Interest on liability (income statement)	144	
Cr Interest on bond (income statement)		100
Cr Liability (statement of financial position)		44

Accretion of income on bond and finance cost of liability

1 January 20X5

	CU	CU
Dr Liability	1,844	
Cr Cash		1,844

Execution of repurchase contract

If (as would be likely, given the nature of the transferred asset) the bank has the right to sell or pledge the bond during the period of its legal ownership, it would be necessary to reclassify the bond as a repurchase receivable during the period of the bank's ownership (see section 4.1.1.A above). In other words, the following additional accounting entries would be required.

1 January 20X4

	CU	CU
Dr Repurchase receivable	2,000	
Cr Bond		2,000

1 January 20X5

	CU	CU
Dr Bond	2,000	
Cr Repurchase receivable		2,000

B Net-settled transaction

The entity might enter into the transaction above, but on terms that the repurchase contract was to be net-settled. In other words, on 1 January 20X5, a payment would be made to or by the bank for the difference between CU1,844 (the notional repurchase price) and the fair value of the bond at that date. Assuming that the fair value of the bond at 1 January 20X5 is CU1,860, the bank would be required to pay the entity CU16 (CU1,860 - CU1,844).

In this case, matters are further complicated by the fact that the economic effect of the net-settled forward is the same as if the entity sold the bond on 1 January 20X5. The following accounting entries would be made:

1 January 20X4

	CU	CU
Dr Cash	1,800	
Cr Liability		1,800

Consideration received from bank

1 January-31 December 20X4

	CU	CU
Dr Interest on liability (income statement)	144	
Cr Interest on bond (income statement)		100
Cr Liability (statement of financial position)		44

Accretion of income on bond and finance cost of liability

1 January 20X5

	CU	CU
Dr Cash	16	
Dr Liability	1,844	
Dr Loss on derecognition of bond	140	
Cr Bond		2,000

Net settlement of repurchase contract and recognition of loss on derecognition of the bond

The loss on derecognition at 1 January 20X5 of CU140 arises because the net-settled contract is equivalent to the entity disposing of the bond for its then fair value of CU1,860, which is CU140 lower than its amortised cost of CU2,000.

This illustrates the point that, where the terms of net-settled forward contract over a transferred asset are such that the original asset cannot be derecognised, the result will be that the entity's statement of financial position shows a gross position - i.e., the original asset and a liability for the consideration for the transfer until the forward contract actually settles. This may seem a strange accounting reflection of a contract that is required to be settled net. However, the IASB was to some extent forced into this approach as an anti-avoidance measure. It is clear from the analysis in sections 4.1.1 to 4.1.4 above that an asset sold subject to the obligation to repurchase the same or similar asset at a fixed price shall not be derecognised. If the accounting treatment were to vary merely because the contract was net-settled, it would be possible to avoid the requirements of IFRS 9 for continued recognition of assets subject to certain forward repurchase agreements simply by altering the terms of the agreement to allow net settlement.

5.3 Transfers with continuing involvement - summary

If an entity neither transfers nor retains substantially all the risks and rewards of ownership of a transferred asset, but retains control of the transferred asset (see section 3.8 above), IFRS 9 requires the entity to continue to recognise the transferred asset to the extent of its 'continuing involvement' - i.e., the extent to which it is exposed to changes in the value of the transferred asset. [IFRS 9.3.2.16]. Such transactions fall within Box 9 of Figure 3-1 in section 3.2 above.

The concept of 'continuing involvement' was first introduced in the exposure draft of proposed amendments to IAS 32 and IAS 39 published in June 2002. The IASB's intention at that time was to move towards an accounting model for derecognition based entirely on continuing involvement. However, this approach (or at least the methodology for implementing it proposed in the exposure draft) received little support in the exposure period and the IASB decided to abandon it and revert largely to an accounting model for derecognition based on the transfer of risks and rewards. [IFRS 9.BC23.4]. Nevertheless, the continuing involvement approach remains relevant for certain transactions - mainly transfers of assets which result in the sharing, rather than the substantial transfer, of the risks and rewards.

The accounting requirements in respect of assets in which the entity has continuing involvement are particularly complex, and are summarised in sections 5.3.1 to 5.3.5 below, with worked examples in section 5.4 below. In particular, and in contrast to the treatment for transactions that do not qualify for derecognition through retention of substantially all risks and rewards (see section 5.2 above), the associated liability is often calculated as a balancing figure that will not necessarily represent the proceeds received as the result of the transfer (see section 5.3.3 below).

We have a general concern regarding the required accounting treatment for a continuing involvement, namely that IFRS 9 provides examples of how to deal with certain specific transactions rather than clear underlying principles. It can be difficult to determine the appropriate treatment for a continuing involvement that does not correspond fairly exactly to one of the examples in IFRS 9.

5.3.1 Guarantees

When the entity's continuing involvement takes the form of guaranteeing the transferred asset, the extent of the entity's continuing involvement is the lower of:

- The carrying amount of the asset
- And
- The maximum amount of the consideration received that the entity could be required to repay ('the guarantee amount') [IFRS 9.3.2.16(a)]

An example of this treatment is given in section 5.4.1 below.

It follows that if the transferor guarantees the entire amount of the transferred asset, no derecognition would be achieved, even though it may have passed other significant risks to the transferee.

5.3.2 Options

When the entity's continuing involvement takes the form of a written and/or purchased option (including a cash-settled option or similar provision) on the transferred asset, the extent of the entity's continuing involvement is the amount of the transferred asset that the entity may repurchase. However, in case of a written put option (including a cash-settled option or similar provision) on an asset measured at fair value, the extent of the entity's continuing involvement is limited to the lower of the fair value of the transferred asset and the option exercise price. *[IFRS 9.3.2.16(b), IFRS 9.3.2.16(c)]*.

Examples of this treatment are given in sections 5.4.2 and 5.4.3 below.

5.3.3 Associated liability

When an entity continues to recognise an asset to the extent of its continuing involvement, IFRS 9 requires the entity to recognise an associated liability. *[IFRS 9.3.2.17]*. IFRS 9 provides that "despite the other measurement requirements in this Standard", the transferred asset and the associated liability are to be measured on a basis that reflects the rights and obligations that the entity has retained. The associated liability is measured in such a way that the net carrying amount of the transferred asset and the associated liability is equal to:

- If the transferred asset is measured at amortised cost, the amortised cost of the rights and obligations retained by the entity
- Or
- If the transferred asset is measured at fair value, the fair value of the rights and obligations retained by the entity when measured on a stand-alone basis *[IFRS 9.3.2.17]*

This has the effect that the 'liability' is often calculated as a balancing figure that will not necessarily represent the proceeds received as the result of the transfer (see Illustration 5-6 to Illustration 5-10 in section 5.4 below). This does not fit very comfortably with the normal rules in IFRS 9 for the initial measurement of financial liabilities (see Chapter 45) - hence the comment that this treatment applies "despite the other measurement requirements in this Standard". Further, the liability cannot be offset against the asset - see section 5.5.1 below.

5.3.4 Subsequent measurement of assets and liabilities

IFRS 9 requires an entity to continue to recognise any income arising on the transferred asset to the extent of its continuing involvement and to recognise any expense incurred on the associated liability. *[IFRS 9.3.2.18]*. This is comparable to the requirements in respect of assets not derecognised through retention of substantially all risks and rewards (see section 5.2 above).

When the transferred asset and associated liability are subsequently measured at fair value through profit and loss, IFRS 9 requires recognised changes in the fair value of the transferred asset and the associated liability to be accounted for consistently with each other in accordance with the general provisions of IFRS 9 for measuring gains and losses (see Chapter 46) and not offset. *[IFRS 9.3.2.19]*. Moreover, if the transferred asset is measured at amortised cost, the option in IFRS 9 to designate a financial liability as at fair value through profit or loss (see Chapter 44) is not applicable to the associated liability. *[IFRS 9.3.2.21]*.

5.3.5 Continuing involvement in part only of a larger asset

An entity may have continuing involvement in a part only of a financial asset, for example where the entity retains an option to repurchase part of a transferred asset, or retains a residual interest in part of an asset, such that the entity does not retain substantially all the risks and rewards of ownership, but does retain control.

In such a case, IFRS 9 requires the entity to allocate the previous carrying amount of the financial asset between the part that it continues to recognise under continuing involvement, and the part that it no longer recognises on the basis of the relative fair values of those parts on the date of the transfer. The allocation is to be made on the same basis as applies on derecognition of part only of a larger financial asset - see sections 5.1.1 and 5.1.2 above.

The difference between:

(a) The carrying amount allocated to the part that is no longer recognised

And

(b) The sum of:

(i) The consideration received for the part no longer recognised

And

(ii) Any cumulative gain or loss allocated to it that had been recognised directly in equity

Is recognised in profit or loss. A cumulative gain or loss that had been recognised in equity is allocated between the part that continues to be recognised and the part that is no longer recognised on the basis of the relative fair values of those parts. [IFRS 9.3.2.13].

The 'recycling' of any cumulative gain or loss previously recognised directly in equity in (b)(ii) above would apply to debt instruments accounted for at fair value through other comprehensive income under IFRS 9. This was previously an explicit requirement of IAS 39, but has not been carried over to IFRS 9, something we suspect is nothing but an oversight.

This topic is discussed further in section 5.4.4 below.

5.4 Transfers with continuing involvement - accounting examples

The application guidance to IFRS 9 provides a number of clarifications and examples that demonstrate the application of the requirements provisions, as summarised in section 5.3 above, the substance of which is reproduced below.

5.4.1 Transfers of assets measured at amortised cost with guarantees

If a guarantee provided by an entity to pay for default losses on a transferred asset prevents the transferred asset from being derecognised to the extent of the continuing involvement, IFRS 9 requires:

(a) The transferred asset at the date of the transfer to be measured at the lower of:

(i) The carrying amount of the asset

And

(ii) The maximum amount of the consideration received in the transfer that the entity could be required to repay ('the guarantee amount')

And

(b) The associated liability to be initially measured at the guarantee amount plus the fair value of the guarantee (which is normally the consideration received for the guarantee)

Subsequently, the initial fair value of the guarantee is recognised in profit or loss on a time proportion basis in accordance with IFRS 15 and the carrying value of the asset is reduced by any impairment losses.

[IFRS 9.B3.2.13(a)].

This is illustrated in Illustration 5-6 below and in Illustration 5-7 below. These Illustrations do not set out the accounting for the continuing involvement in the transferred asset after the transfer, for example the recognition of expected credit losses.

Illustration 5-6: Continuing involvement through guarantee

An entity has a loan portfolio carried at CU10 million with a fair value of CU10.5 million. It sells the rights to 100% of the cash flows to a third party for a payment of CU10.55 million, which includes a payment of CU50,000 in return for the entity agreeing to absorb the first CU1 million of default losses on the portfolio. The loans are fixed rate loans with significant prepayment risk.

The guarantee has the effect that the entity has transferred substantially all the rewards, but not substantially all the risks, of the portfolio (Figure 3-1, Box 6, No). The prepayment risk and interest rate risk have been transferred to the transferee, so that the entity does not retain all significant risks of the loans (Figure 3-1, Box 7, No). The portfolio is not a readily marketable asset, so that the entity retains control of the asset (Figure 3-1, Box 8, Yes - see also section 3.8 above), and the continuing involvement provisions of IFRS 9 apply (Figure 3-1, Box 9).

The entity turns to the requirements above. The continuing involvement in the transferred asset must be measured at the lower of:

- (i) The carrying amount of the asset transferred - i.e., CU10 million
- And
- (ii) The maximum amount of the consideration received in the transfer that the entity could be required to repay - i.e., CU1 million (the amount guaranteed)

Therefore, the entity will set up an asset that represents its continuing involvement in the transferred asset of CU1 million.

The entity then considers the carrying amount of the liability. This is required to be measured at the guarantee amount (i.e., CU1 million) plus the fair value of the guarantee (i.e., the CU50,000 guarantee payment), a total of CU1.05 million. Therefore, the entity's continuing involvement in the transaction will be reflected as follows:

	CU m	CU m
Dr Cash	10.55	
Dr Continuing involvement in the transferred asset	1.00	
Cr Loan portfolio transferred		10.00
Cr Continuing involvement liability		1.05
Cr Profit on disposal*		0.50

* Cash received (CU10.55 million) less guarantee payment (CU50,000) = consideration for portfolio (CU10.5 million) less carrying amount of portfolio (CU10 million).

Over the remaining life of the transaction, the CU50,000 of the liability that represents the consideration received for the guarantee is amortised to the income statement on a time proportion basis. This has the effect that the income earned by the entity for entering into the guarantee arrangement is reported as revenue on a time proportion basis [IFRS 9.4.2.1(c)(ii)].

Amortisation of the premium over the remaining life of the transaction

	CU	CU
Dr Continuing involvement liability	0.05	
Cr Profit or loss		0.05

If in a subsequent period credit losses of CU0.2 million are suffered, requiring a payment under the guarantee, IFRS 9 requires the following accounting entries to be made:

	CU m	CU m
Dr Profit or loss (loss under guarantee)	0.20	
Dr Continuing involvement liability	0.20	
Cr Cash (paid to transferee)		0.20
Cr Continuing involvement in the transferred asset		0.20

At maturity of the guarantee, assuming no further losses, the following entry will be recorded:

	CU m	CU m
Dr Continuing involvement liability (CU1 - CU0.2)	0.80	
Cr Continuing involvement in the transferred asset		0.80

Illustration 5-7: Continuing involvement through guarantee covering 'slow payment risk'

An entity enters into a securitisation in which it transfers trade receivables (with a notional value of CU100 and an amortised cost of CU98 after recognising an expected credit loss allowance of CU2) to an SPE for consideration of CU97. The entity also retains the slow payment risk (the risk that the receivables pay later than the due date) to a limited extent through a 'funding charge' determined as an interest charge of 8% applied to the balance of any receivables that remain outstanding beyond their due date for a maximum of 60 days. Beyond 60 days, all slow payment risk (plus default risk) resides with the SPE.

The entity does not control the SPE, and therefore does not consolidate the SPE. It is determined that the transfer is a qualifying transfer and the entity neither retains nor transfers substantially all of the risks and rewards of ownership of the trade receivables, due to the retention of significant slow payment risk, but has retained control over the assets since the slow payment guarantee would preclude sales of the trade receivables by the transferee. Therefore, in accordance with IFRS 9.3.2.16(a), the entity continues to recognise the trade receivables to the extent of its continuing involvement.

Below we illustrate an example of how an entity could account for this scenario.

The entity derecognises the CU98 of trade receivables and, instead, recognises an asset representing the extent of the continuing involvement in the receivables which would be measured as $CU100 \times 8\% \times (60 \div 365) = CU1.32$.

The entity must also recognise a liability, calculated so that the net of the asset of CU1.32 and the liability is equal to the fair value of the obligation retained, i.e., the slow payment risk. Hence, if the fair value of the retained obligation is CU0.5, the entity recognises an asset of CU1.32 and a liability of CU1.82.

The entity therefore recognises a loss on the transfer of the receivables of CU1.50 as follows:

	CU	CU
Dr Cash	97.00	
Dr Continuing involvement in the transferred asset	1.32	
Dr Loss on disposal	1.50	
Cr Trade receivables (CU100 - CU2)		98.00
Cr Continuing involvement liability		1.82

The entity records the following entries subsequent to the transfer:

Amortisation of the premium over the sixty days guaranteed period

	CU	CU
Dr Continuing involvement liability	0.50	
Cr Profit or loss		0.50

The following entry is made at maturity of the guarantee if there are no claims made during the guaranteed period

	CU	CU
Dr Continuing involvement liability	1.32	
Cr Continuing involvement in the transferred asset		1.32

The following entry is made if there are claims of CU0.2 made during the guaranteed period and subsequently paid

	CU	CU
Dr Profit or loss	0.20	
Dr Continuing involvement liability	0.20	
Cr Cash		0.20
Cr Continuing involvement in the transferred asset		0.20

At maturity of the guarantee, assuming no further losses, the following entry would be recorded

	CU m	CU m
Dr Continuing involvement liability (CU1.32 - CU0.2)	1.12	
Cr Continuing involvement in the transferred asset		1.12

5.4.2 Transfers of assets measured at amortised cost with an option

If a put or call option prevents derecognition (see sections 3.7.3 and 4.2 above) of a transferred asset measured at amortised cost, IFRS 9 requires the associated liability to be measured at cost (i.e., the consideration received) and subsequently adjusted for the amortisation of any difference between that cost and the amortised cost of the transferred asset at the expiration date of the option, as illustrated by Illustration 5-8 below. [IFRS 9.B3.2.13(b)].

Illustration 5-8: Asset measured at amortised cost

An entity has a financial asset, accounted for at amortised cost, carried at CU98. It transfers the asset to a third party in return for consideration of CU95. The asset is subject to a call option whereby the entity can compel the transferee to sell the asset back to the entity for CU102. The amortised cost of the asset on the option exercise date will be CU100. The option is considered to be neither deeply in the money nor deeply out of the money. IFRS 9 therefore requires the entity to continue to recognise the asset to the extent of its continuing involvement (Figure 3-1, Box 9 - see also section 4.2.3 above).

The initial carrying amount of the associated liability is CU95. This is then accreted to CU100 (i.e., the amortised cost of the asset on exercise date - not the CU102 exercise price) through profit or loss using the effective interest method. Because the transferred asset is measured at amortised cost, the associated liability must also be accounted for at amortised cost, and not at fair value through profit or loss (see section 5.3.4 above). This will give rise to the following accounting entries:

Date of transfer

	CU	CU
Dr Cash	95	
Cr Liability		95

After date of transfer

	CU	CU
Dr Interest on liability	5	
Dr Asset (CU100 - CU98)	2	
Cr Liability (CU100 - CU95)		5
Cr Income on asset		2

If the option is exercised, any difference between the carrying amount of the associated liability and the exercise price is recognised in profit or loss. This last requirement has the possibly counter-intuitive effect, that the question of whether the entity records a profit or loss on exercise of the option, is essentially a function of the difference between the liability (representing the amortised cost of the transferred asset) and the cash paid, not of whether it has in fact (i.e., in economic terms) made a gain or loss.

Thus, if the entity were to exercise its option at CU102 it would apparently record the accounting entry:

	CU	CU
Dr Liability	100	
Dr Loss	2	
Cr Cash		102

However, the entity would not have exercised the option unless the asset had been worth at least CU102 (i.e., CU2 more than its carrying amount), suggesting that the more appropriate treatment would be to add the CU2 to the cost of the asset.

Likewise, if instead of the entity having a call option, the transferee had a put option at CU98 which it exercised, the entity would apparently record the accounting entry:

	CU	CU
Dr Liability	100	
Cr Profit		2
Cr Cash		98

However, the transferee would not have exercised its option unless the asset had been worth less than CU98 (i.e., CU2 less than its carrying amount). In this case, however, the IASB's thinking may have been that the exercise of the transferee's put option suggests an impairment of the asset which is required to be recognised in the financial statements (see Chapter 47). This would not necessarily be the case (e.g., where a fixed-interest asset has a fair value below cost because of movements in interest rates but is not intrinsically impaired).

If the option were to lapse unexercised, the entity would simply derecognise the transferred asset and the associated liability, i.e.,:

		CU	CU
Dr	Liability	100	
	Cr Asset		100

5.4.3 Transfers of assets measured at fair value with an option

IFRS 9 discusses the application of continuing involvement accounting to transferred assets measured at fair value in terms of transferred assets subject to:

- A transferor's call option (see section 5.4.3.A below)
 - A transferee's put option (see section 5.4.3.B below)
- And
- A 'collar' - i.e., a transferor's call option combined with a transferee's put option (see section 5.4.3.C below)

The way in which the rules are articulated in IFRS 9 is somewhat confusing, but in general the effect is that the transferred asset is recognised at:

- In the case of an asset subject to a transferor call option, its fair value (on the basis that the call option gives the transferor access to any increase in the fair value of the asset).
- And
- In the case of an asset subject to a transferee put option, the lower of fair value and the option exercise price (on the basis that the put option denies the transferor access to any increase in the fair value of the asset above the option price).

This methodology summarised below is applied both on the date on which the option is written and subsequently.

5.4.3.A Transferor's call option

If a transferor's call option prevents derecognition (see sections 3.7.3 and 4 above) of a transferred asset measured at fair value, the asset continues to be measured at its fair value. The associated liability is measured:

- If the option is in or at the money, at the option exercise price less the time value of the option
- Or
- If the option is out of the money, at the fair value of the transferred asset less the time value of the option

The adjustment to the measurement of the associated liability ensures that the net carrying amount of the asset and the associated liability is the fair value of the call option right, as illustrated by Illustration 5-9 below. [IFRS 9.B3.2.13(c)].

Illustration 5-9: Asset measured at fair value subject to transferor's call option

An entity has a financial asset, accounted for at fair value through profit or loss, carried at CU80. It transfers the asset to a third party for CU75, subject to a call option whereby the entity can compel the transferee to sell the asset back to the entity for CU95. At the date of transfer, the call option has a time value of CU5.

The option is considered to be neither deeply in the money nor deeply out of the money. IFRS 9 therefore requires the entity to continue to recognise the asset to the extent of its continuing involvement (Figure 3-1, Box 9 - see also section 4.2.3 above), and to continue recording it at fair value. At the date of transfer, the call option is out of the money. IFRS 9 therefore requires the liability to be measured at the fair value of the transferred asset less the time value of the option, i.e., CU80 - CU5 = CU75. This has the result that the net of the carrying value of the asset (CU80) and the carrying value of the liability (CU75) equals the time value of the option (CU5), resulting in the following accounting entry:

Date of transfer

		CU	CU
Dr	Cash	75	
	Cr Liability		75

A Transferred asset increases in value

Suppose that one year later the fair value of the asset is CU100 and the time value of the option is now CU3. The option is now in the money, so that the liability is measured at the option exercise price less the time value of the option, i.e., $CU95 - CU3 = CU92$. This has the result that the net of the carrying value of the asset (CU100) and the carrying value of the liability (CU92) equals the fair value of the option (CU8, representing CU3 time value and CU5 intrinsic value). The liability could have been more straightforwardly calculated as the fair value of the asset (CU100) less the fair value of the option (CU8) = CU92. This gives rise to the following accounting entries:

During year 1

		CU	CU
Dr	Asset (CU100 - CU80)	20	
	Cr Liability (CU92 - CU75)		17
	Cr Gain (profit or loss)		3

The CU3 gain recorded in profit or loss effectively represents the increase in the fair value of the option from CU5 to CU8 over the period. If the entity were able to exercise the option at this point, and did so, it would record the entry:

		CU	CU
Dr	Liability	92	
Dr	Loss (profit or loss)	3	
	Cr Cash		95

The particular transaction results in no overall gain or loss being reflected in profit or loss (i.e., CU3 gain during the year less CU3 loss on exercise of option). This represents the net of the CU20 gain in the fair value of the asset (CU100 at the end of period less CU80 at the start) and the net cash outflow of CU20 (CU75 in on initial transfer, CU95 out on exercise of option). Alternatively, it could be considered that the entity has paid CU5 for the option (representing the time value at inception), which is offset against the gain made on the intrinsic value of CU8 on exercise.

B Asset decreases in value

Suppose instead that during the first year the fair value of the asset fell to CU65 and the time value of the option at the end of the year was only CU1. The liability would be measured at the fair value of the transferred asset less the time value of the option, i.e., $CU65 - CU1 = CU64$. This would generate the accounting entries:

During year 1

		CU	CU
Dr	Liability (CU64 - CU75)	11	
Dr	Loss (profit or loss)	4	
	Cr Asset (CU65 - CU80)		15

Again, the overall loss shown in profit or loss represents the movement in the fair value of the option over the period from CU5 to CU1. Suppose that one year later there was no change in the fair value of the asset, and the option expired unexercised. The entity would then record the accounting entry:

At end of year 2

		CU	CU
Dr	Liability	64	
Dr	Loss (profit or loss)	1	
	Cr Asset (statement of financial position)		65

This results in an overall loss for the transaction as a whole of CU5 (CU4 in year 1 and CU1 in year 2), which represents the option premium of CU5 paid on the date of transfer (i.e., the difference between the fair value of the asset at the date of original transfer (CU80) and the proceeds received (CU75)), which expired out of the money.

5.4.3.B Transferee's put option

If a transferee's put option prevents derecognition (see sections 3.7.3 and 4 above) of a transferred asset measured at fair value, IFRS 9 requires the asset to be measured at the lower of fair value and the option exercise price. The basis for this treatment is that the entity has no right to increases in the fair value of the transferred asset above the exercise price of the option. The associated liability is measured at the option exercise price plus the time value of the option. This ensures that the net carrying amount of the asset and the associated liability is the fair value of the put option obligation, as illustrated by Illustration 5-10 below. [IFRS 9.B3.2.13(d)].

Illustration 5-10: Asset measured at fair value subject to transferee's put option

An entity has a financial asset, accounted for at fair value. On 1 January 20X2 it transfers the asset, then carried at CU98, to a third party, subject to a put option whereby the transferee can compel the entity to reacquire the asset for CU100. The option is considered to be neither deeply in the money nor deeply out of the money. IFRS 9 therefore requires the entity to continue to recognise the asset to the extent of its continuing involvement (Figure 3-1, Box 9 - see also section 4.2.3 above), and to continue recording it at the lower of (a) fair value and (b) CU100 (the exercise price of the option). Assuming that the transferee pays CU106 for the asset, representing CU98 fair value of the asset plus CU8 time value of the option, the entity would record the accounting entry:

1 January 20X2

		CU	CU
Dr	Cash	106	
	Cr Liability		106

A Transferred asset increases in value

Suppose that at 31 December 20X2, the option has a time value of CU5 and the fair value of the asset is CU120. IFRS 9 requires the carrying value of the asset to be restricted to CU100 (the exercise price of the option). The liability is measured at the exercise price plus the time value of the option, i.e., CU100 + CU5 = CU105. This has the result that the net of the carrying value of the asset (CU100) and the carrying value of the liability (CU105) equals the fair value of the option to the transferor (-CU5). The fair value of an in the money option is positive for the buyer and negative for the writer.

This gives the accounting entry:

31 December 20X2

		CU	CU
Dr	Asset (CU100 - CU98)	2	
Dr	Liability (CU105 - CU106)	1	
	Cr Gain (profit or loss)		3

The gain of CU3 effectively represents the decrease in the time value of the option (a gain from the transferor's perspective) from CU8 to CU5.

If the option were then to lapse unexercised, with no further change in the fair value of the asset, the entity would record the accounting entry:

On lapse of option

		CU	CU
Dr	Liability	105	
	Cr Asset		100
	Cr Gain (profit or loss)		5

The total gain on the transaction of CU8 (CU3 in Year 1 and CU5 on lapse) represents the option premium of CU8 (i.e., the difference between the total consideration of CU106 and the fair value of the asset of CU98) received at the outset.

B Transferred asset decreases in value

Suppose instead that at 31 December 20X2, the option has a time value of CU5 but the fair value of the asset is CU90. IFRS 9 requires the carrying value of the asset to be measured at its fair value of CU90. The liability is measured at the exercise price plus the time value of the option (i.e., to the transferee), i.e., CU100 + CU5 = CU105.

This gives the accounting entry:

31 December 20X2

		CU	CU
Dr	Liability (CU105 - CU106)	1	
Dr	Loss (profit or loss)	7	
	Cr Asset (CU90 - CU98)		8

This has the result that the net of the carrying value of the asset (CU90) and the liability (CU105), i.e., (-CU15) represents the fair value of the option to the transferor (i.e., intrinsic value (-CU10) (CU100 exercise price versus CU90 value of asset) + time value (-CU5)). The CU7 loss represents the increase in the fair value of the option (a loss to the transferor) from CU8 at the outset to CU15 at 31 December 20X2.

If the transferee were able to, and did, exercise its option at that point, the entity would record the accounting entry:

On exercise of option

		CU	CU
Dr	Liability	105	
	Cr Cash		100
	Cr Gain (profit or loss)		5

The overall CU2 loss (i.e., CU5 gain above and CU7 loss during Year 1) represents the net cash of CU6 received from the transferee (CU106 in at inception less CU100 out on exercise) less the CU8 fall in fair value of the transferred asset (CU98 at inception less CU90 at exercise).

5.4.3.C 'Collar' put and call options

Assets may be transferred in a way designed to ensure that the transferee is shielded from excessive losses on the transferred asset but has to pass significant gains on the asset back to the transferor. Such an arrangement is known as a 'collar', on the basis that it allocates a range of potential value movements in the asset to the transferee, with movements outside that range accruing to the transferor. A simple example would be the transfer of an asset subject to a purchased call option (allowing the transferor to reacquire the asset if it increases in value beyond a certain level) and a written put option (allowing the transferee to compel the transferor to reacquire the asset if it falls in value beyond a certain level).

If a collar, in the form of a purchased call and written put option, prevents derecognition (see sections 3.7.3 and 4 above) of a transferred asset measured at fair value, IFRS 9 requires the entity to continue to measure the asset at fair value. The associated liability is measured at:

- If the call option is in or at the money, the sum of the call exercise price and the fair value of the put option less the time value of the call option.
- Or
- If the call option is out of the money, the sum of the fair value of the asset and the fair value of the put option less the time value of the call option.

The adjustment to the associated liability ensures that the net carrying amount of the asset and the associated liability is the fair value of the options held and written by the entity, as illustrated by Illustration 5-11 below. [IFRS 9.B3.2.13(e)].

Illustration 5-11: Asset measured at fair value subject to collar put and call options

An entity has a financial asset, accounted for at fair value, carried at CU100. On 1 January 20X2 it transfers the asset to a third party, subject to:

- A call option whereby the entity can compel the transferee to sell the asset back to the entity for CU120
- And
- A put option whereby the transferee can compel the entity to reacquire the asset for CU80

The options are considered to be neither deeply in the money nor deeply out of the money. IFRS 9 therefore requires the entity to continue to recognise the asset to the extent of its continuing involvement (Figure 3-1, Box 9 - see also section 4.2.3 above), and to continue recording it at fair value.

At the date of transfer, the time value of the put and call are CU1 and CU5 respectively. At the date of transfer, the call option is out of the money, so that the associated liability is calculated as the sum of the fair value of the asset and the fair value of the put option less the time value of the call option, i.e., $(CU100 + CU1) - CU5 = CU96$. The net of this and the fair value of the asset (CU100) is CU4 which is the net fair value of the two options (call CU5 less put CU1). Assuming that the transaction is undertaken at arm's length, the transferee would pay CU96 for the asset and the entity would record the accounting entry:

		CU	CU
Dr	Cash	96	
	Cr Liability		96

A Transferred asset increases in value

Suppose that, at 31 December 20X2, the fair value of the asset is CU140, and the time value of the put and call are CU0.5 and CU2 respectively. The call option is now in the money, so that IFRS 9 requires the entity to recognise a liability equal to the sum of the call exercise price and fair value of the put option less the time value of the call option, i.e., $(CU120 + CU0.5) - CU2 = CU118.5$. The net of this and the carrying value of the asset (CU140) is CU21.5 which is the net fair value of the two options (call CU22 [time value CU2 plus intrinsic value CU20] less put CU0.5 = CU21.5). This gives the accounting entry:

31 December 20X2

		CU	CU
Dr	Asset (CU140 - CU100)	40.0	
	Cr Gain (profit or loss)		17.5
	Cr Liability (CU118.5 - CU96)		22.5

The gain represents the increase in fair value of the call option of CU17 (CU5 at outset and CU22 at 31 December 20X2) plus the CU0.5 decrease (a gain from the transferor's perspective) in the fair value of the put option (CU1 at outset and CU0.5 at 31 December 20X2).

If the entity were able to, and did, exercise its call option, it would record the entry:

Exercise of call option

		CU	CU
Dr	Liability	118.5	
Dr	Loss (profit or loss)	1.5	
	Cr Cash		120.0

The overall gain of CU16 on the transaction (CU1.5 loss above and CU17.5 profit recorded in 20X2) represents the increase in fair value of the asset of CU40 (CU100 at outset, CU140 at 31 December 20X2) less the net CU24 paid to the transferee (CU120 paid on exercise of call less CU96 received on initial transfer).

B Transferred asset decreases in value

Suppose instead that, at 31 December 20X2, the fair value of the asset is CU78, and the time value of the put and call are CU0.5 and CU2 respectively. The call option is now out of the money, so that IFRS 9 requires the entity to recognise a liability equal to the sum of the fair value of the asset and the fair value of the put option (i.e., $CU2.5 - \text{time value } CU0.5 \text{ plus intrinsic value } CU2$ [CU80 exercise price versus CU78 fair value of asset]) less the time value of the call option, i.e., $(CU78 + CU2.5) - CU2 = CU78.5$.

The net of this and the carrying value of the asset (CU78) is (-CU0.5) which is the net fair value of the two options (call CU2 less put CU2.5 = -CU0.5). This gives the accounting entry:

31 December 20X2

		CU	CU
Dr	Liability (CU78.5 - CU96)	17.5	
Dr	Loss (profit or loss)	4.5	
	Cr Asset (CU78 - CU100)		22.0

The loss represents the decrease in the fair value of the call option of CU3 (CU5 at outset and CU2 at 31 December 20X2) plus the CU1.5 increase (a decrease from the transferor's perspective) in the fair value of the put option (CU1 at outset and CU2.5 at 31 December 20X2).

If the transferee were able to, and did, exercise its put option, the entity would record the entry:

Exercise of put option

		CU	CU
Dr	Liability	78.5	
Dr	Loss (profit or loss)	1.5	
	Cr Cash		80.0

The overall loss of CU6 on the transaction (CU1.5 loss above and CU4.5 loss recorded in 20X2) represents the decrease in fair value of the asset of CU22 (CU100 at outset, CU78 at 31 December 20X2) offset by the net CU16 received from the transferee (CU96 received on initial transfer less CU80 paid on exercise of put).

5.4.4 Continuing involvement in part only of a financial asset

IFRS 9 gives the following example of the application of the continuing involvement approach to continuing involvement in part only of a financial asset. [IFRS 9.B3.2.17].

Illustration 5-12: Continuing involvement in part only of a financial asset

An entity has a portfolio of prepayable loans whose coupon and effective interest rate is 10% and whose principal amount and amortised cost is CU10 million. It enters into a transaction in which, in return for a payment of CU9.115 million, the transferee obtains the right to CU9 million of any collections of principal plus 9.5% interest.

The entity retains rights to CU1 million of any collections of principal plus interest at 10%, plus the remaining 0.5% ('excess spread') on the remaining CU9 million of principal. Collections from prepayments are allocated between the entity and the transferee proportionately in the ratio of 1:9, but any defaults are deducted from the entity's interest of CU1 million until that interest is exhausted.

The fair value of the loans at the date of the transaction is CU10.1 million and the estimated fair value of the excess spread of 0.5% is CU40,000.

The entity determines that it has transferred some significant risks and rewards of ownership (for example, significant prepayment risk) but has also retained some significant risks and rewards of ownership because of its subordinated retained interest (Figure 3-1, Box 7, No) and has retained control (Figure 3-1, Box 8, Yes). It therefore applies the continuing involvement approach (Figure 3-1, Box 9).

The entity analyses the transaction as:

- A retention of a fully proportionate retained interest of CU1 million
- Plus
- The subordination of that retained interest to provide credit enhancement to the transferee for credit losses

The entity calculates that CU9.09 million (90% of CU10.1 million) of the consideration received of CU9.115 million represents the consideration for a fully proportionate 90% share. The remainder of the consideration (CU25,000) received represents consideration received by the entity for subordinating its retained interest to provide credit enhancement to the transferee for credit losses. In addition, the excess spread of 0.5% represents consideration received for the credit enhancement. Accordingly, the total consideration received for the credit enhancement is CU65,000 (CU25,000 received from transferee plus CU40,000 fair value of excess spread).

The entity calculates the gain or loss on the sale of the 90% share of cash flows. Assuming that separate fair values of the 90% part transferred and the 10% part retained are not available at the date of the transfer, the entity allocates the carrying amount of the asset in accordance with paragraph 3.2.14 of IFRS 9 as follows:

	Fair value	Percentage	Allocated carrying amount
Portion transferred	9,090	90%	9,000
Portion retained	1,010	10%	1,000
Total	10,100		10,000

The entity computes its gain or loss on the sale of the 90% share of the cash flows by deducting the allocated carrying amount of the portion transferred from the consideration received, i.e., CU90 (CU9,090 - CU9,000). The carrying amount of the portion retained by the entity is CU1,000.

In addition, IFRS 9 requires the entity to recognise the continuing involvement that results from the subordination of its retained interest for credit losses. Accordingly, it recognises an asset of CU1 million (the maximum amount of the cash flows it would forfeit under the subordination), and an associated liability of CU1.065 million (the maximum amount of the cash flows it would forfeit under the subordination, i.e., CU1 million, plus the fair value of the guarantee considered to be equal to the consideration received for the subordination of CU65,000). It also recognises an asset for the fair value of the excess spread which forms part of the consideration for the subordination.

This gives rise to the following accounting entry:

	CU'000	CU'000
Dr Cash	9,115	
Dr Asset for the subordination of the residual interest (continuing involvement in the transferred asset)	1,000	
Dr Excess spread received for subordination	40	
Cr Loan portfolio		9,000
Cr Liability for subordination (continuing involvement liability)		1,065
Cr Gain on disposal		90

It is crucial to an understanding of this example that, as a result of the transaction, the original asset (the portfolio of prepayable loans) is being accounted for as two separate assets. Because the cash flows from the portfolio are split in fully proportionate (*pro rata*) shares (see section 3.4 above), each of these assets must be considered separately.

The first of these assets, the right to cash flows of CU9 million obtained by the transferee, continues to be recognised only to the extent of the entity's continuing involvement, which in this case is via the credit enhancement. The approach is very similar to continuing involvement through guarantee (see Illustration 5-6 in section 5.4.1 above), except that the liability for subordination includes the maximum cash flow that the entity might not receive from its retained share (i.e., CU1 million) rather than, as in Illustration 5-6, a potential cash outflow (the guarantee amount, which is the maximum amount that the entity could be required to repay). This is aggregated with the fair value of the amount received in respect of the credit enhancement, in order to calculate the full liability for subordination. This is similar to the way in which the fair value of the guarantee is added to the guarantee amount in order to calculate the associated liability. [IFRS 9.B3.2.13(a)].

The second asset is the entity's proportionate retained share of CU1 million.

The effect is to gross up the statement of financial position with a subordination asset and liability. As IFRS 9 notes, immediately following the transaction, the carrying amount of the asset is CU2.04 million (i.e., CU1 million part retained plus CU1 million subordination asset plus CU40,000 excess spread) - in respect of an asset whose fair value is only CU1.01 million.

5.5 Miscellaneous provisions

IFRS 9 contains a number of accounting provisions generally applicable to transfers of assets, as discussed below.

5.5.1 Offset

IFRS 9 provides that, if a transferred asset continues to be recognised, the entity must not offset:

- The asset with the associated liability
Or
- Any income arising from the transferred asset with any expense incurred on the associated liability
[IFRS 9.3.2.22]

Whilst IFRS 9 does not say so specifically, this is clearly intended to apply both to assets that continue to be recognised in full and to those that continue to be recognised to the extent of their continuing involvement.

This requirement apparently overrides the offset criteria in IAS 32, [IAS 32.42], as illustrated, for example, by the various situations highlighted in the discussion in section 4 and sections 5.1 to 5.4 above where a transaction required to be net-settled (which would normally be required to be accounted for as such under IAS 32) is accounted for as if it were to be gross-settled.

5.5.2 Collateral

If a transferor provides non-cash collateral (such as debt or equity instruments) to the transferee, the accounting treatment for the collateral by both the transferor and the transferee depends on:

- Whether the transferee has the right to sell or repledge the collateral
And
- Whether the transferor has defaulted

If the transferee has the right by contract or custom to sell or repledge a collateral asset, the transferor shall reclassify that asset in its statement of financial position (e.g., as a loaned asset, pledged equity instruments or repurchase receivable) separately from other assets.

If the transferee sells collateral pledged to it, it recognises the proceeds from the sale and a liability measured at fair value for its obligation to return the collateral.

If the transferor defaults under the terms of the contract and is no longer entitled to redeem the collateral, it derecognises the collateral, and the transferee either:

- Recognises the collateral as its asset initially measured at fair value
Or
- If it has already sold the collateral, derecognises its obligation to return the collateral

In no other circumstances shall the transferor derecognise, or the transferee recognise, the collateral as an asset. [IFRS 9.3.2.23].

5.5.3 Rights or obligations over transferred assets that continue to be recognised

Where a transfer of a financial asset does not qualify for derecognition, the transferor may well have contractual rights or obligations related to the transfer, such as options or forward repurchase contracts that are derivatives of a type that would normally be required to be recognised under IFRS 9.

IFRS 9 prohibits separate recognition of such derivatives, if recognition of the derivative together with either the transferred asset or the liability arising from the transfer would result in recognising the same rights or obligations twice.

For example, IFRS 9 notes that a call option retained by the transferor may prevent a transfer of financial assets from being accounted for as a sale (see section 4 above). In that case, the call option shall not be separately recognised as a derivative asset. [IFRS 9.B3.2.14].

We would expect a similar approach to be taken to contractual rights associated with a non-derivative financial instrument issued to the transferor by the transferee in a transfer that does not qualify for derecognition. This commonly occurs when financial assets are transferred to a securitisation vehicle which issues a subordinated loan to the transferor as a result of which substantially all risks and rewards of the financial assets are retained by the transferor. In such case, only the cash received from the vehicle would be recorded as a liability.

5.6 Reassessing derecognition

IFRS 9 states that if an entity determines that, as a result of the transfer, it has transferred substantially all the risks and rewards of ownership of the transferred asset, it does not recognise the transferred asset again in a future period, unless it reacquires the transferred asset in a new transaction. [IFRS 9.B3.2.6]. We have noted earlier that there is some ambiguity as to whether this rule in IFRS 9.B3.2.6 is to be read generally as prohibiting any re-recognition of a derecognised asset or specifically as referring only to circumstances where derecognition results from transfer of substantially all the risks and rewards (i.e., it applies only to 'Box 6, Yes' transactions, and not to 'Box 8, No' transactions).

How we see it

Our view, as expressed in section 4.2 above, is that derecognition arising as a result of a transfer where substantially all the risks and rewards have been transferred cannot be reassessed following developments in the future. We would expect entities to apply this principle more broadly and include scenarios where derecognition occurs as a result of loss of control.

The risks and rewards of ownership retained by the entity may change as a result of market changes in such a way that, had the revised conditions existed at inception, they would have prevented derecognition of the asset. However, the original decision to derecognise the asset is not revisited, unless (in exceptional circumstances) the original assessment was an accounting error within the scope of IAS 8.

5.6.1 Reassessment of consolidation of subsidiaries and SPEs

As mentioned in Section 3.2, the first step of the derecognition analysis, when preparing consolidated financial statements, is to ensure all subsidiaries, including those that are SPEs, are consolidated. This is because many transactions that could result in derecognition of one subsidiary's financial assets involve transactions with another member of the group, but these transactions will be eliminated on consolidation. The assessment as to whether a particular SPE is controlled by the reporting entity is discussed in Chapter 7.

In the context of a securitisation, if an SPE (or issuer) is consolidated by the originator, then all intragroup transactions are eliminated and only the externally held notes issued by the SPE will be accounted for. In most cases, the originator will not derecognise the securitised assets, but instead recognise the loan notes as financial liabilities, unless the issuer is able to demonstrate that it operates as a qualifying pass-through arrangement. For more guidance on pass-through arrangements refer to section 3.6.2.

If the issuer is not consolidated by the originator, the originator may derecognise the assets transferred to the SPE that is not consolidated, using the remaining steps of the derecognition analysis. The application of IFRS 9 to securitisations is dealt with further in section 3.6.1 and section 3.6.2.

IFRS 10 requires an investor to reassess whether it controls an investee if facts and circumstances indicate that there are changes to any elements of control, including the investor's exposure, or rights, to variable returns from its involvement with the investee (see Chapter 7). [IFRS 10.8]. As such, there is a possibility that due to a subsequent deconsolidation of the transferee, the group may reach a different conclusion regarding the derecognition of the assets transferred.

6 Derecognition - financial liabilities

The provisions of IFRS 9 with respect to the derecognition of financial liabilities are generally more straightforward and less subjective than those for the derecognition of financial assets. However, they are also very different from the asset derecognition rules which focus primarily on the economic substance of the transaction. By contrast, the rules for derecognition of liabilities, like the provisions of IAS 32 for the identification of instruments as financial liabilities (see Chapter 43), focus more on legal obligations.

IFRS 9 contains provisions relating to:

- The extinguishment of debt (see section 6.1 below)
- The substitution or modification of debt by the original lender (see section 6.2 below)
- And
- The calculation of any profit or loss arising on the derecognition of debt (see section 6.3 below)

Extract from IFRS 9

- 3.3.1** An entity shall remove a financial liability (or a part of a financial liability) from its statement of financial position when, and only when, it is extinguished—ie when the obligation specified in the contract is discharged or cancelled or expires.
- 3.3.2** An exchange between an existing borrower and lender of debt instruments with substantially different terms shall be accounted for as an extinguishment of the original financial liability and the recognition of a new financial liability. Similarly, a substantial modification of the terms of an existing financial liability or a part of it (whether or not attributable to the financial difficulty of the debtor) shall be accounted for as an extinguishment of the original financial liability and the recognition of a new financial liability.
- 3.3.3** The difference between the carrying amount of a financial liability (or part of a financial liability) extinguished or transferred to another party and the consideration paid, including any non-cash assets transferred or liabilities assumed, shall be recognised in profit or loss.
- 3.3.4** If an entity repurchases a part of a financial liability, the entity shall allocate the previous carrying amount of the financial liability between the part that continues to be recognised and the part that is derecognised based on the relative fair values of those parts on the date of the repurchase. The difference between (a) the carrying amount allocated to the part derecognised and (b) the consideration paid, including any non-cash assets transferred or liabilities assumed, for the part derecognised shall be recognised in profit or loss.

[IFRS 9.3.3.1, IFRS 9.3.3.2, IFRS 9.3.3.3, IFRS 9.3.3.4].

6.1 Extinguishment of debt

IFRS 9 requires an entity to derecognise (i.e., remove from its statement of financial position) a financial liability (or a part of a financial liability - see section 6.1.1 below) when, and only when, it is 'extinguished', that is, when the obligation specified in the contract is discharged, cancelled, or expires. [IFRS 9.3.3.1]. This will be achieved when the debtor either discharges the liability (or part of it) by paying the creditor, or is legally released from primary responsibility for the liability (or part of it) either by process of law or by the creditor. [IFRS 9.B3.3.1]. Extinguishment of liabilities by legal release is discussed further in section 6.1.2 below. Situations whereby debt is repurchased by the issuer and unit-linked products are dealt with in section 6.1.5 below.

In September 2021, the IFRS IC was asked when a financial asset settled by a cash payment received via an electronic transfer system is derecognised. The discussion was extended to include the derecognition of a financial liability settled by a payment in the same scenario. The IFRS IC identified diversity in practice for the timing of derecognition of financial assets and financial liabilities, not just those settled via an electronic transfer system, but also using other methods. As a result of this, the IFRS IC decided to hand this matter over to the IASB who included this in the *Amendments to the Classification and Measurement of Financial Instruments* published in May 2024.

2024 Amendments Applicable for annual periods beginning on or after 1 January 2026 (with earlier application permitted)

The Amendments clarify that a financial liability is only derecognised on the settlement date [IFRS 9.B3.1.2A], which is the date on which the liability is extinguished because the obligation specified in the contract is discharged or cancelled or expires or the liability otherwise qualifies for derecognition. [IFRS 9.B3.1.2A].

To address some operational concerns raised by stakeholders, the IASB also developed new requirements to permit an entity to derecognise, before the settlement date, a financial liability that will be settled in cash using an electronic payment system [IFRS 9.B3.3.8]. This narrow-scope exception from the settlement date accounting principle of IFRS 9 B3.1.2A is shown below.

Extract from IFRS 9

- B3.3.8** Despite the requirement in paragraph B3.1.2A to derecognise a financial liability on the settlement date, when settling a financial liability (or part of a financial liability) in cash using an electronic payment system, an entity is permitted to deem the financial liability (or part of it) to be discharged before the settlement date if, and only if, the entity has initiated a payment instruction that resulted in:
- (a) the entity having no practical ability to withdraw, stop or cancel the payment instruction;
 - (b) the entity having no practical ability to access the cash to be used for settlement as a result of the payment instruction; and
 - (c) the settlement risk associated with the electronic payment system being insignificant.
- B3.3.9** For the purpose of applying paragraph B3.3.8(c), settlement risk associated with an electronic payment system is insignificant if its characteristics are such that completion of the payment instruction follows a standard administrative process and the time between the criteria in paragraphs B3.3.8(a) and (b) being met and the cash being delivered to the counterparty is short. However, settlement risk would not be insignificant if completion of the payment instruction were subject to the entity's ability to deliver cash on the settlement date.
- B3.3.10** An entity that elects to apply paragraph B3.3.8 to the settlement of a financial liability (or part of a financial liability) using an electronic payment system shall apply that paragraph to all settlements made through the same electronic payment system.

If used, this exception from the settlement date accounting principle needs to be consistently applied on a system-by-system basis [IFRS 9.B3.3.10]. Using this exception, an entity will need to assess what 'no practical ability to withdraw, stop or cancel the payment instruction' and 'insignificant settlement risk' means in its context. These assessments should be consistently applied.

How we see it

For financial liabilities, entities need to establish a thorough understanding of the various cash settlement mechanisms and when their amount payable that is being settled via that mechanism is transformed into a cash balance for the counterparty. This could be a complex matter, especially for entities operating with multiple payment systems and with cross-border operations.

A similar analysis will be required for entities seeking to apply the exception for financial liabilities, to assess whether and when the relevant criteria in IFRS 9.B3.3.8 are met, including with respect to the 'practical ability' requirements, which will require some judgement.

Where the conclusion is unclear (e.g., due to the features of the payment systems and/or the interaction with multiple payment systems and with laws and regulations of different jurisdictions), legal opinions could be required to establish when a liability has been extinguished.

If a financial liability is derecognised before the settlement date through the use of the exemption, then the corresponding credit entry is the cash account used for the transaction [IFRS 9.BC3.61].

Prior to the Amendments, there was no explicit statement in the Standard or Basis for Conclusions that a financial liability could only be recognised when the cash has been received by the counterparty. Therefore, entities may have derecognised a financial liability at an earlier point.

How we see it

Given that the IASB had to issue Amendments to the standard to clarify the requirements in this area, in our view, an entity is not required to change its accounting policy on the timing of derecognition of a financial liability to conform with the Amendments until when those are adopted. At that point, it can make use of the transitional guidance in IFRS 9.7.2.48.

6.1.1 What constitutes 'part' of a liability?

The requirements of IFRS 9 for the derecognition of liabilities apply to all or 'part' of a financial liability. It is not entirely clear what is meant by 'part' of a liability in this context. The rules, and the examples, in IFRS 9 seem to be drafted in the context of transactions that settle all remaining cash flows (i.e., interest and principal) of a proportion of a liability, such as the repayment of CU25 million of a CU100 million loan, together with any related interest payments.

However, these provisions are presumably also intended to apply in situations where an entity prepays the interest only (or a proportion of future interest payments) or the principal only (or a proportion of future principal payments) on a loan.

6.1.2 Legal release by creditor

A liability can be derecognised by a debtor if the creditor legally releases the debtor from the liability. It is clear that IFRS 9 regards legal release as crucial, with the effect that very similar (if not identical) situations may lead to different results purely because of the legal form.

For example, IFRS 9 provides that:

- Where a debtor is legally released from a liability, derecognition is not precluded by the fact that the debtor has given a guarantee in respect of the liability. [IFRS 9.B3.3.1(b)].
- But
- If a debtor pays a third party to assume an obligation and notifies its creditor that the third party has assumed the debt obligation, the debtor derecognises the debt obligation if, and only if, the creditor legally releases the debtor from its obligations. [IFRS 9.B3.3.4].

The effect of these requirements is shown by Illustration 6-1.

Illustration 6-1: Transfer of debt obligations with and without legal release

Scenario 1

Entity A issues bonds that have a carrying amount and fair value of CU1,000,000. A pays CU1,000,000 to Entity B for B to assume responsibility for paying interest and principal on the bonds to the bondholders. The bondholders are informed that B has assumed responsibility for the debt. However, A is not legally released from the obligation to pay interest and principal by the bondholders. Accordingly, if B does not make payments when due, the bondholders may seek payment from A.

Scenario 2

Entity A issues bonds that have a carrying amount and fair value of CU1,000,000. A pays CU1,000,000 to Entity B for B to assume responsibility for paying interest and principal on the bonds to the bondholders. The bondholders are informed that B has assumed responsibility for the debt and legally release A from any further obligation under the debt. However, A enters into a guarantee arrangement whereby, if B does not make payments when due, the bondholders may seek payment from A.

It is reasonably clear that in either scenario above the bondholders are in the same economic and legal position - they will receive payments from B and, if B defaults, they will have recourse to A.

However, IFRS 9 gives rise to the anomalous result that:

- Scenario 1 is accounted for by the continuing recognition of the debt because no legal release has been obtained.
- But
- Scenario 2 is accounted for by derecognition of the debt, and recognition of a new guarantee, notwithstanding that the effect of the guarantee is to put A back in the same position as if it had not been released from its obligations under the original bond.

IFRS 9 also clarifies that, if a debtor:

- Transfers its obligations under a debt to a third party and obtains legal release from its obligations by the creditor
 - But
 - Undertakes to make payments to the third party so as to enable it to meet its obligations to the creditor
- It derecognises the original debt, but recognises a new debt obligation to the third party. [IFRS 9.B3.3.4].

Legal release may also be achieved through the novation of a contract to an intermediary counterparty. For example, a derivative between a reporting entity and a bank may be novated to a CCP. In these circumstances, the IASB explains that the novation to the CCP releases the bank from the responsibility to make payments to the reporting entity. Consequently, the original derivative meets the derecognition criteria for a financial liability and a new derivative with the CCP is recognised. [IFRS 9.BC6.335]. However, for hedge accounting purposes only, it is sometimes possible in these circumstances to treat the new derivative as a continuation of the original (see Chapter 49).

6.1.3 'In-substance defeasance' arrangements

Entities sometimes enter into so-called 'in-substance defeasance' arrangements in respect of financial liabilities. These typically involve a lump sum payment to a third party (other than the creditor) such as a trust, which then invests the funds in (typically) very low-risk assets to which the entity has no, or very limited, rights of access. These assets are then applied to discharge all the remaining interest and principal payments on the financial liabilities that are purported to have been defeased.

It is sometimes argued that the risk-free nature of the assets, and the entity's lack of access to them, means that the entity is in substance in no different position than if it had actually repaid the original financial liability. However, IFRS 9 regards such arrangements as not giving rise to derecognition of the original liability in the absence of legal release by the creditor. [IFRS 9.B3.3.3].

6.1.4 Extinguishment in exchange for transfer of assets not meeting the derecognition criteria

IFRS 9 notes that in some cases legal release may be achieved by transferring assets to the creditor which do not meet the criteria for derecognition (see section 3 above). In such a case, the debtor will derecognise the liability from which it has been released, but recognise a new liability relating to the transferred assets that may be equal to the derecognised liability. [IFRS 9.B3.3.5]. It is not entirely clear what is envisaged here, but it may be some such scenario as the following.

Illustration 6-2: Extinguishment of debt in exchange for transfer of assets not meeting derecognition criteria

An entity has a bank loan of CU1 million. The bank agrees to accept in full payment of the loan the transfer to it by the entity of a portfolio of corporate bonds with a market value of CU1 million. The entity and the bank then enter into a put and call option over the bonds, the effect of which will be that the entity will repurchase the bonds in three years' time at a price that gives the bank a lender's return on CU1 million. As discussed further in section 4.2.8 above, this would have the effect that the entity is unable to derecognise the bonds.

Under the provisions of IFRS 9, the entity would be able to derecognise the original bank loan, as it has been legally released from it. The provisions under discussion here have the overall result that a loan effectively continues to be recognised. Strictly, however, the analysis is that the original loan has been derecognised and a new one recognised. In effect the accounting is representing that the entity has repaid the original loan and replaced it with a new one secured on a bond portfolio.

We expect in this instance, the application of the requirement in IFRS 9.B3.3.5 to be based on IFRS 9.3.2.15, which requires the liability to reflect the consideration received. The consideration received in this instance likely reflects the fair value of the old loan that the borrower was legally released from.

6.1.5 Debt repurchased by the issuer

If the issuer of a debt instrument repurchases the instrument, the debt is extinguished even if the issuer is a market maker in that instrument, or otherwise intends to resell or reissue it in the near term. [IFRS 9.B3.3.2]. IFRS 9 focuses only on whether the entity has a legal obligation to reissue the debt, not on whether there is a commercial imperative for it to do so.

To cater for entities issuing unit-linked products or contracts with discretionary participation features, a limited exception to the requirement in paragraph B3.3.2 has been introduced on adoption of IFRS 17 *Insurance Contracts*, which became effective for periods beginning on or after 1 January 2023. [IFRS 9.7.1.6]. The conditions for using this exemption are set out in below extract.

Extract from IFRS 9

3.3.5 Some entities operate, either internally or externally, an investment fund that provides investors with benefits determined by units in the fund and recognise financial liabilities for the amounts to be paid to those investors. Similarly, some entities issue groups of insurance contracts with direct participation features and those entities hold the underlying items. Some such funds or underlying items include the entity's financial liability (for example, a corporate bond issued). Despite the other requirements in this Standard for the derecognition of financial liabilities, an entity may elect not to derecognise its financial liability that is included in such a fund or is an underlying item when, and only when, the entity repurchases its financial liability for such purposes. Instead, the entity may elect to continue to account for that instrument as a financial liability and to account for the repurchased instrument as if the instrument were a financial asset, and measure it at fair value through profit or loss in accordance with this Standard. That election is irrevocable and made on an instrument-by-instrument basis. For the purposes of this election, insurance contracts include investment contracts with discretionary participation features. (See IFRS 17 for terms used in this paragraph that are defined in that Standard.)

6.2 Exchange or modification of debt by original lender

It is common for an entity, particularly but not necessarily when in financial difficulties, to approach its major creditors for a restructuring of its debt commitments - for example, an agreement to postpone the repayment of principal in exchange for higher interest payments in the meantime, or to roll up interest into a single 'bullet' payment of interest and principal at the end of the term. Such changes to the terms of debt can be effected in a number of ways, in particular:

- A notional repayment of the original loan followed by an immediate re-lending of all or part of the proceeds of the notional repayment as a new loan ('exchange')

Or

- Legal amendment of the original loan agreement ('modification')

The accounting issue raised by such transactions is essentially whether there is, in fact, anything to account for. For example, if an entity owes CU100 million at floating rate interest and negotiates with its bankers to change the interest to a fixed coupon of 7%, does the accounting treatment have to reflect the fact that:

- (a) The entity still owes CU100 million to the same lender, and so is in the same position as before?

Or

- (b) The modification of the interest profile has altered the net present value of the total obligations under the loan?

When a loan is repaid at maturity and a new loan is taken out with the same lender, this would not be a modification or exchange as the original loan was not modified or exchanged, it was settled in accordance with the original contractual terms. However, sometimes an existing loan will be replaced by a new one with the same lender before its maturity date. In these circumstances judgement will be required to assess whether to regard the original loan as being modified or exchanged or whether it should be regarded as being repaid and replaced by a new loan on market terms. This judgement involves consideration of how close to the maturity date of the original loan the transaction took place, compared to the term of the original loan. For example, if the transaction took place three months before the maturity of a 10-year loan, it is more likely to be considered a repayment and replacement than if the transaction took place six months before the maturity of a one-year loan.

IFRS 9 requires an exchange between an existing borrower and lender of debt instruments with 'substantially different' terms to be accounted for as an extinguishment of the original financial liability and the recognition of a new financial liability. Similarly, a substantial modification of the terms of an existing financial liability, or a part of it, (whether or not due to the financial difficulty of the debtor) shall be accounted for as an extinguishment of the original financial liability and the recognition of a new financial liability. [IFRS 9.3.3.2]. The determination of whether an exchange or modification is substantially different is discussed further in section 6.2.1 below.

In August 2020, the IASB issued amendments to IFRS 9 to provide guidance on how to account for modifications of a financial liability due to the reform of interbank offered rates and this is discussed further in section 6.2.2 below.

Large borrowing arrangements may be transacted with multiple lenders in loan syndications and the issues arising from such arrangements are discussed further in section 6.2.3 below.

Sometimes a borrower may effect an exchange of debt through an intermediary and this is discussed further in section 6.2.4 below.

The accounting consequences for an exchange or a modification that results in extinguishment and one that does not lead to extinguishment are discussed in further detail in sections 6.2.5 to 6.2.7 below.

6.2.1 When is an exchange or modification of debt ‘substantially different’?

IFRS 9 regards the terms of exchanged or modified debt as ‘substantially different’ if the net present value of the cash flows under the new terms (including any fees paid net of any fees received) discounted at the original effective interest rate is at least 10% different from the discounted present value of the remaining cash flows of the original debt instrument. [IFRS 9.B3.3.6]. This comparison is commonly referred to as ‘the 10% test’.

Whilst IFRS 9 does not say so explicitly, it seems clear that the discounted present value of the remaining cash flows of the original debt instrument used in the 10% test must also be determined using the original effective interest rate, so that there is a ‘like for like’ comparison. This amount should also represent the amortised cost of the liability prior to modification.

In May 2020 the IASB issued *Annual Improvements to IFRS Standards 2018-2020*, which included amendments to IFRS 9 to clarify that only fees paid or received between the borrower and lender are included in the 10% test, therefore fees payable such as to the entity’s legal advisors are excluded. The IASB believes that the clarification aligns with the objective of the test, which is to quantitatively assess the significance of any difference between the old and new contractual terms on the basis of the changes in the contractual cash flows between the borrower and lender. The amendments had to be adopted prospectively and had an effective date of periods commencing 1 January 2022 [IFRS 9.7.1.9, IFRS 9.7.2.35, IFRS 9.B3.3.6].

Under certain circumstances extinguishment accounting for an exchange or modification of a liability may still be required, even where the net present value of the cash flows under the new terms is less than 10% different from the discounted present value of the remaining cash flows of the original debt instrument. Indeed, there may be situations where the modification of the debt is so fundamental that immediate derecognition is required whether or not the 10% test is satisfied. The following are examples of situations where derecognition of the original instrument could be required:

- An entity has issued a ‘plain vanilla’ debt instrument and restructures the debt to include an embedded equity instrument.
- An entity has issued a 5% euro-denominated debt instrument and restructures the instrument to an 18% Turkish lira-denominated debt instrument.

The present value of the cash flows of such restructured debts, discounted at the original effective interest rate, may not be significantly different from the discounted present value of the remaining cash flows of the original financial liability. However, the determination of the revised cashflows would require more judgemental assumptions compared to the original cash flows, which in itself could be an indicator that the modification is substantial. Further, even if the 10% test is not satisfied, the introduction of the equity-linked feature or a change in currency (unless the original and new currencies are pegged) could significantly alter the future economic risk exposure of the instrument.

How we see it

In the circumstances above the modification of terms are, in our view, regarded as representing a substantial change which would lead to derecognition of the original liability.

There are other modifications to the contractual terms of financial liabilities which may be considered substantial and therefore result in extinguishment accounting, for example a change in the basis of interest calculation (such as moving from fixed to floating rate) or a significant extension in the term of the debt. The assessment of such modifications will require judgement and they are to be considered along with other modifications made at the same time before concluding whether the modifications should be considered substantial.

6.2.2 Interbank Offered Rate (IBOR) Reform

Following recommendations from the Financial Stability Board there have been various initiatives to replace current benchmark interest rates, such as interbank offered rates like LIBOR, with nearly risk-free rates. In view of these initiatives and the resulting uncertainty around the long-term viability of IBORs, the IASB responded with two separate amendments. The Phase 1 Amendments (effective for years beginning on or after 1 January 2020, but with early application permitted) address the accounting consequences that may arise prior to the replacement of IBORs and the Phase 2 Amendments (effective for years beginning on or after 1 January 2021, but again with early application permitted) address the accounting consequences that arise from changes to contractual cash flows required by the replacement of IBORs.

For a comprehensive discussion the IASB's amendments to IFRS in response to IBOR reform, see *Supplement: IBOR Reform*.

6.2.3 Loan syndications

Large borrowing arrangements for a single borrower are often funded by multiple lenders in a process referred to as 'loan syndication'. In such circumstances the borrower must determine whether this arrangement represents a single loan with a single lender (often referred to as the 'lead lender') who enters into a sub-participation arrangement with the other lenders, or whether the arrangement represents multiple loans with multiple lenders. This determination will affect how changes to the arrangement are considered by the borrower to determine whether they represent a modification of the borrower's financial liability or an extinguishment of the original financial liability and the recognition of a new financial liability.

Where the borrower determines that it has a single loan agreement with a single lead lender, changes to this agreement must be considered by the borrower on an aggregate basis to determine whether the changes represent a modification or an extinguishment. Meanwhile, changes in the composition of the syndicate may not be relevant to the borrower, as long as the lead lender stays the same.

Where the borrower determines that it has multiple loans with multiple lenders, the borrower would consider changes to the borrowing arrangements with each lender separately. If one lender is replaced by a different lender, then the borrower must consider whether the replacement represents an extinguishment of the original loan and its replacement by another.

The assessment will require an analysis of the legal terms of the contract. Factors that need to be considered, individually or in combination, in assessing whether there is a single loan or multiple loans include the following:

- The borrower negotiates loan terms only with the lead lender or with individual lenders within the syndicate.
- The loan terms are identical or differ, depending on the lender.
- Loan repayments are automatically allocated among lenders on a *pro rata* basis, or the borrower may be able to selectively repay amounts to specific lenders within the syndicate.
- The borrower can only renegotiate with the lead lender or may selectively renegotiate loans with individual lenders or subsets of lenders within the syndicate.

And

- Members of the syndicate may change without the permission of the borrower or such a change may require an amendment to the loan agreement.

6.2.4 Exchange of debt through an intermediary

Where a borrower repurchases a debt from an existing lender and immediately issues new debt to the same lender this is normally considered an exchange and the derecognition assessment will depend on whether the terms of the new and original debt are substantially different (see section 6.2.1 above). However, if a borrower repurchases debt from one or more existing lenders and issues new debt to new (i.e., different) lenders, then the existing debt is derecognised.

Rather than approach the existing lenders directly, a borrower may effect such an exchange through an intermediary (e.g., a bank). In such situations the intermediary might purchase existing debt held by existing lenders, and exchange it for new debt with the borrower, which is then transferred to new lenders shortly afterwards. In these situations, the borrower must determine whether the intermediary is acting as a principal (i.e., as lender) or is acting as an agent of the borrower.

If the intermediary is acting as a principal, then the transaction between the issuer and the intermediary is considered a debt exchange between an existing borrower and existing lender and derecognition is assessed based on whether the terms are substantially different. If the terms are not substantially different the debt is not derecognised.

If the intermediary is acting as an agent, the derecognition is assessed assuming the intermediary does not exist. In other words the borrower will be seen as repurchasing debt from existing lenders (resulting in its derecognition) and issuing new debt to new lenders.

The determination of whether the intermediary is acting as a principal or an agent will depend on the terms of the arrangements and the extent to which the intermediary is exposed to any risks. For example, where the intermediary risks its own funds to acquire the existing debt, is responsible for placing the new debt with new investors and is required to hold any debt that it is unable to sell on, it is more likely to be acting as a principal. Alternatively, if the intermediary does not risk its own funds to any significant degree, for example by agreeing to buy only the debt that it is able to sell on, it is more likely to be acting as an agent.

6.2.5 Costs and fees

An entity will almost always be required to pay fees to the lender and incur costs (such as legal expenses) on an exchange or modification of a financial liability.

If an exchange of debt instruments or modification of terms is accounted for as an extinguishment of the original debt and the recognition of new debt, IFRS 9 requires any costs or fees incurred to be recognised as part of the gain or loss on the extinguishment (see section 6.3 below). [IFRS 9.B3.3.6A].

However, notwithstanding a literal reading of IFRS 9, there may be very limited circumstances when fees or costs associated with the issue of new debt do not need to be included in the gain or loss on extinguishment. Where it is obvious that the fees have not been incurred as part of the modification or exchange and instead are third party costs, which are clearly incremental to the issue of new debt for example payments of taxes or listing fees on the issue of new debt, then an entity may choose to adopt a policy whereby such costs are deducted from the carrying value of the new debt and amortised over its term, as long as the new debt is not classified as held at fair value through profit or loss. Examples of such costs will be limited as they must be clearly separate from costs related to the modification or exchange.

Where the exchange or modification is not accounted for as an extinguishment, any costs or fees incurred adjust the carrying amount of the liability and are amortised over the remaining term of the modified liability. [IFRS 9.B3.3.6A]. This is shown in the following illustration:

Illustration 6-3: Fees and costs incurred on modification of debt not treated as extinguishment

On 1 January 20X0 an entity borrowed CU100 million on, at that time, arm's length market terms, so that interest of 6% was to be paid annually in arrears and the loan repaid in full on 31 December 20X4. Transaction costs of CU4 million were incurred. Assuming that the loan had run to term, the entity would have recorded the following amounts using the effective interest method. The loan is originally recorded at the issue proceeds of CU100 million less transaction costs of CU4 million, and the effective interest rate of 6.975% is determined. For a more detailed discussion of the effective interest method, see Chapter 46.

Year	Liability opening balance	Interest at 6.975%	Cash paid	Liability closing balance
	CU m	CU m	CU m	CU m
1.1.20X0	96.00			96.00
20X0	96.00	6.70	(6.00)	96.70
20X1	96.70	6.74	(6.00)	97.44
20X2	97.44	6.80	(6.00)	98.24
20X3	98.24	6.85	(6.00)	99.09
20X4	99.09	6.91	(106.00)	-

During the latter part of 20X1 the entity considers expanding its business in a way that would crystallise the lender's right to demand immediate repayment of the loan because such an action is not permitted under the detailed terms of the loan. Therefore, the entity approaches the lender with a view to amending those terms to permit the planned expansion, but without changing the cash flows on the loan. On 1 January 20X2, the lender agrees to amend the terms in return for which it charges the entity a fee of CU450,000. The entity also incurs directly attributable legal costs of CU50,000, bringing the total fees and costs incurred to CU500,000.

It can be shown that the net present value of the cash flows under the new terms, including the CU0.45 million of fees paid (but excluding the CU0.05 million of legal costs in line with the amendments to IFRS 9 within the *Annual Improvements to IFRS Standards 2018-2020* noted in section 6.2.1 above), discounted at the original effective interest rate is CU97.89 million. This compares to the carrying amount of CU97.44 million and because the remaining cash flows have not changed, the difference between the two simply represents the fees paid. This difference is just 0.46% of the original carrying amount, significantly less than 10%. The entity does not consider the changes to the detailed terms of the loan to be substantial and therefore concludes the modification does not result in the extinguishment of the liability.

Accordingly, the carrying amount of the liability is adjusted by the CU500,000 fees and costs incurred so that the revised carrying amount is CU96.94 million (CU97.44 million less CU0.50 million). In order to amortise this adjustment over the remaining term of the loan, the entity resets the effective interest rate of the loan, in this case to 7.170%, so that it is amortised in accordance with the effective interest method as follows:

Year	Liability opening balance	Interest at 7.169%	Cash paid	Liability closing balance
	CU m	CU m	CU m	CU m
1.1.20X2	96.94			96.94
20X2	96.94	6.95	(6.00)	97.89
20X3	97.89	7.02	(6.00)	98.91
20X4	98.91	7.09	(106.00)	-

It will be necessary to consider whether the substance of the CU0.45m in fees payable is different from its form, e.g., it may be more appropriate to account for a payment that is described as a fee as if it were a modification to the contractual cash flows, for example when the payment represents compensation for the lender's loss of future interest or compensation for increased risk (see section 6.2.6 below).

6.2.6 Modification gains and losses

In Illustration 6-3 in section 6.2.5 above, the remaining cash flows on the loan remained the same after the modification, but in practice they will often change. For example, in the situation set out in Illustration 6-3, if the substance of the CU450,000 fee had actually been a compensation for increased risk, the lender might have equally agreed to charge additional interest of, say, CU170,000 per year for the remaining three-year term of the loan instead of the CU450,000 fee at the time of the modification. Detailed calculations show an almost identical outcome when applying the 10% test to these revised facts, with the net present value of the cash flows under revised terms being CU97.89 million excluding the CU50,000 of legal costs, a difference of CU0.45 million or 0.46%. Again, it would be concluded that the modification does not result in derecognition of the liability.

IFRS 9 requires modifications of financial liabilities that do not result in derecognition to be accounted for similarly to modifications of financial assets (see Chapter 46). The amortised cost of the financial liability is recalculated by computing the present value of estimated future contractual cash flows that are discounted at the financial instrument's original effective interest rate. Any consequent adjustment will be recognised immediately in profit or loss. [IFRS 9.B5.4.6, IFRS 9.BC4.252, IFRS 9.BC4.253].

In the situation discussed above, this would result in the entity recognising a modification loss of CU450,000, being the net present value of the additional interest payable of CU170,000 per annum, discounted at the original effective interest rate of 6.975%.

This is different to the facts in Illustration 6-3 where the fees are assumed not to represent a modification to the contractual cash flows. This example highlights that the accounting treatment for costs and fees paid to the lender is different from that for changes to future cash flows paid to the lender. The former are amortised over the remaining term of the modified liability, the effects of the latter being recognised immediately in profit or loss.

How we see it

Therefore, in our view, it will be necessary to consider in some situations whether the substance of a payment is different from its form, e.g., it may be more appropriate to account for a payment that is described as a fee as if it were a modification to the contractual cash flows, for example when the payment represents compensation for the lender's loss of future interest or compensation for increased risk. This assessment may require some judgement to be applied.

6.2.7 Illustrative examples

Illustration 6-4 and Illustration 6-5 below illustrate some more complex modifications of debt.

Illustration 6-4: Modification of debt not treated as extinguishment

On 1 January 20X7 an entity borrowed CU100 million on, at that time, arm's length market terms, so that interest of 7% was to be paid annually in arrears and the loan repaid in full on 31 December 20X6. Transaction costs of CU5 million were incurred. Assuming that the loan had run to term, the entity would have recorded the following amounts using the effective interest method. The loan is originally recorded at the issue proceeds of CU100 million less transaction costs of CU5 million, and the effective interest rate is 7.736%.

Year	Liability b/f	Interest at 7.736%	Cash paid	Liability c/f
	CU m	CU m	CU m	CU m
1.1.20X7	95.00			95.00
20X7	95.00	7.35	(7.00)	95.35
20X8	95.35	7.38	(7.00)	95.73
20X9	95.73	7.40	(7.00)	96.13
20Y0	96.13	7.44	(7.00)	96.57
20Y1	96.57	7.47	(7.00)	97.04
20Y2	97.04	7.51	(7.00)	97.55
20Y3	97.55	7.55	(7.00)	98.10
20Y4	98.10	7.59	(7.00)	98.69
20Y5	98.69	7.63	(7.00)	99.32
20Y6	99.32	7.68	(107.00)	-

During 20Y1 the entity is in financial difficulties and approaches the lender for a modification of the terms of the loan. These are agreed on 1 January 20Y2, as follows. No cash interest will be payable in 20Y2 or 20Y3, although a fee of CU2 million must be paid to the lender immediately. From 20Y4 onwards interest of 9% on the CU100 million outstanding will be payable annually in arrears and the term of the loan will be extended for two years until 31 December 20Y8. Legal fees and other costs incurred are not material.

The entity is required to compute the present value of the new arrangement using the original effective interest rate of 7.736%. This gives a net present value for the modified debt of CU92.53 million, calculated as follows:

Year	Cash flow	CU m	Discount factor	CU m
1.1.20Y2	Fee	2.00	1	2.00
20Y4	Interest	9.00	1/1.07736 ³	7.20
20Y5	Interest	9.00	1/1.07736 ⁴	6.68
20Y6	Interest	9.00	1/1.07736 ⁵	6.20
20Y7	Interest	9.00	1/1.07736 ⁶	5.75
20Y8	Interest and principal	109.00	1/1.07736 ⁷	64.70
			Total	92.53

This represents 95.4% of the current carrying value of the debt as at the end of 20Y1 of CU97.04 million, so that the net present value of the modified loan (discounted at the effective interest rate of the original loan) is 4.6% different from that of the original loan. This is less than 10%, so that the modification is not automatically required to be treated as an extinguishment under IFRS 9.

As noted in section 6.2.6 above, an entity recognises an immediate gain or loss when the cash flows on a loan are modified and the liability is not derecognised. In this situation this would result in the recognition of a gain of CU6.51 million (CU97.04 million current carrying value less CU90.53 million recalculated net present value, excluding the fees, which as set out in section 6.2.5 above adjust the carrying amount of the liability and are amortised over its remaining term). Allocating the fee based upon the effective interest method would result in an increase in the effective interest rate to 8.1213%.

The adjusted carrying amount of the liability of CU88.53 million (CU90.53 million net present value of cash flows on the borrowing less CU2 million fee) would be accreted using the effective interest method as follows:

Year	Liability b/f	Interest at 8.1213%	Cash paid	Liability c/f
	CU m	CU m	CU m	CU m
20Y2	88.53	7.19	-	95.72
20Y3	95.72	7.77	-	103.49
20Y4	103.49	8.41	(9.00)	102.90
20Y5	102.90	8.36	(9.00)	102.26
20Y6	102.26	8.30	(9.00)	101.56
20Y7	101.56	8.25	(9.00)	100.81
20Y8	100.81	8.19	(109.00)	-

Illustration 6-5: Modification of debt treated as extinguishment

Assume the same facts as in Illustration 6-4 above, except that on 1 January 20Y2 the entity comes to an arrangement with the lender to modify the terms of the loan as follows.

No cash interest will be paid in 20Y2 or 20Y3, although a fee of CU2 million must be paid to the lender immediately. From 20Y4 onwards interest of 12.5% will be paid annually in arrears, and the term of the loan will be extended for three years until 31 December 20Y9. Legal fees and other costs incurred are not material.

As in Illustration 6-4 above, the entity is required to compute the net present value of the new arrangement using the original effective interest rate of 7.736%. This gives a net present value for the modified debt of CU107.3 million calculated as follows:

Year	Cash flow	CU m	Discount factor	CU m
1.1.20Y2	Fee	2.00	1	2.00
20Y4	Interest	12.50	1/1.07736 ³	10.00
20Y5	Interest	12.50	1/1.07736 ⁴	9.28
20Y6	Interest	12.50	1/1.07736 ⁵	8.61
20Y7	Interest	12.50	1/1.07736 ⁶	7.99
20Y8	Interest	12.50	1/1.07736 ⁷	7.42
20Y9	Interest and principal	112.50	1/1.07736 ⁸	61.98
			Total	107.28

This represents 110.6% of the current carrying value of the debt as at the end of 20Y1 of CU97.04 million, so that the net present value of the modified loan (discounted at the effective interest rate of the original loan) is 10.6% different from that of the original loan. This is greater than 10%, so the modification is required to be treated as an extinguishment.

This will involve derecognising the existing liability and recognising a new liability. The modified loan must - in accordance with the initial measurement provisions of IFRS 9 (see Chapter 45) - be recognised at fair value and its amortised cost must be based on its own effective interest rate, not that applicable to the original loan.

The fee of CU2 million, which is required to be treated as integral to the cash flows of the modified loan for the purposes of comparing it with the original loan, must be expensed immediately if the test identifies an extinguishment and not be included in the effective interest calculation of the new loan.

The difficulty is obviously in determining the fair value of the modified loan. If the loan was in the form of a quoted bond, a market value might be available. Another possible approach might be to discount the cash flows of the modified loan at the interest rate at which the entity could have issued a new loan on similar terms to the modified loan. However, where (as may well be the case) the modification is being undertaken because the entity is in serious financial difficulty, it might be that no lender would be prepared to advance new finance, so that there are no comparable transactions to derive the borrowing rate from. Nevertheless, IFRS 9 contains no exemption from making an estimate of the fair value of the modified loan, and it would not be appropriate to simply assume that the nominal value of the new loan is the same as its fair value.

If it was assessed that the fair value of the modified loan was CU98 million, the accounting treatment for the modification would be (see also section 6.3 below):

		CU m	CU m
Dr	Original loan	97.04	
Dr	Loss on extinguishment of debt (income statement)	2.96	
Cr	Modified loan		98.00
Cr	Cash (fee)		2.00

In this particular case, this has the result that the actual gain or loss recognised (CU2.96 million) is smaller than the difference calculated between the net present value of the original and modified loan that led to the requirement to recognise the gain or loss in the first place, which is CU10.24 million (CU107.28 million - CU97.04 million). This differential will obviously be reflected in higher interest costs as the transaction matures. If the borrower was in financial difficulties, it is possible for the fair value of the modified loan to be significantly below its principal amount, which could give rise to a large profit on modification followed by very high interest charges over the remaining term.

6.2.8 Settlement of financial liability with issue of new equity instrument

A related area is the accounting treatment to be adopted where an entity issues non-convertible debt, but subsequently enters into an agreement with the debt-holder to discharge the liability under the debt in full or in part for an issue of equity instruments. This most often occurs when the entity is in financial difficulties. This topic is now dealt with in IFRIC 19 *Extinguishing Financial Liabilities with Equity Instruments* which is discussed in Chapter 43.

6.3 Gains and losses on extinguishment of debt

When a financial liability (or part of a liability) is extinguished or transferred to another party, IFRS 9 requires the difference between the carrying amount of the transferred financial liability (or part of a liability) and the consideration paid, including any non-cash assets transferred or liabilities assumed, to be recognised in profit or loss. [IFRS 9.3.3.3].

If an entity repurchases only a part of a financial liability, it calculates the carrying value of the part disposed of (and hence the gain or loss on disposal) by allocating the previous carrying amount of the financial liability between the part that continues to be recognised and the part that is derecognised based on the relative fair values of those parts on the date of the repurchase. [IFRS 9.3.3.4]. In other words, the carrying amount of the liability is not simply reduced by consideration received.

This is illustrated in Illustration 6-6 below.

Illustration 6-6: Partial derecognition of debt

On 1 January 20X0 an entity issues 500 million CU1 10-year bonds which are traded in the capital markets. Issue costs of CU15 million were incurred and the carrying value of the bonds at 31 December 20X3 is CU490 million. On 31 December 20X3 the entity makes a market purchase of 120 million bonds at their then current market price of CU0.97. The entity records the following accounting entry:

		CU m	CU m
Dr	Bonds ($120 \div 500 \times \text{CU}490$ million)	117.6	
Cr	Cash ($120 \text{ million} \times \text{CU}0.97$)		116.4
Cr	Gain on repurchase of debt		1.2

2024 amendments applicable for annual periods beginning on or after 1 January 2026 (with earlier application permitted)

In July 2024, the IASB published a narrow-scope amendment regarding the derecognition of lease liabilities recognised by a lessee. The amendment, clarifies that, when a lessee has determined that a lease liability has been extinguished in accordance with IFRS 9, the lessee is required to apply paragraph 3.3.3 of IFRS 9 and recognise any resulting gain or loss in profit or loss [IFRS 9.2.1(b)(ii)].

However, the amendment does not address how a lessee distinguishes between a lease modification as defined in IFRS 16 *Leases* and an extinguishment of a lease liability in accordance with IFRS 9. For further guidance on the accounting for lease liabilities, please refer to Chapter 24 *Leases*.

The guidance on extinguishment of a liability in IFRS 9.3.3.3 previously did not apply to lease liabilities [IFRS 9(2014).2.1(b)(ii)], therefore entities are able to continue their existing accounting practice until the narrow-scope amendments become effective.

6.4 Derivatives that can be financial assets or financial liabilities

A derivative which involves two-way payments between parties, i.e., the payments are or could be from and to each of the parties, is derecognised only when it meets both the derecognition criteria for a financial asset and the derecognition criteria for a financial liability. [IFRS 9.BC6.333]. In practice, any transfer of such derivatives is likely to require the consent of the counterparty to the entity's legal release from its obligations under the contract, and the possible payment of a fee to compensate the counterparty for the difference between the creditworthiness of the entity and that of the transferee. Such procedures are much closer to those envisaged in the derecognition rules for financial liabilities than those implicit in the derecognition rules for financial assets.

6.5 Supply-chain finance

In December 2020 the IFRS IC finalised an agenda decision on reverse factoring arrangements, in which a financial institution agrees to pay amounts an entity owes to the entity's suppliers and the entity agrees to pay the financial institution at a date later than suppliers are paid. The decision focused on reverse factoring arrangements because the IFRS IC's outreach and research indicated that these are the most common supply-chain financing arrangements. While the decision only mentioned reverse factoring arrangements, it may be appropriate to apply the guidance to other types of supply-chain financing. The IFRS IC concluded that the principles and requirements in IFRS accounting standards provides an adequate basis for an entity to determine the presentation of liabilities that are part of reverse factoring arrangements.

Although the final agenda decision largely addresses presentation, disclosure and cash flow classification matters, it does state that an entity assesses whether and when to derecognise a liability that is (or becomes) part of a reverse factoring arrangement by applying the derecognition requirements in IFRS 9. Derecognition could occur if the purchaser is legally released from its original obligation to the supplier (see section 6.1.2 above) or the terms of the original liability are amended in a way that is considered a substantial modification (see section 6.2.1 above).

In May 2023, the IASB finalised its project on *Supplier Finance Arrangements*, which amended IAS 7 and IFRS 7. These additional disclosure requirements, are discussed in more detail in Chapter 36 and Chapter 50.

7 CUSIP 'netting'

The Committee on Uniform Securities Identification Procedures (CUSIP) number of a security is a unique identification number assigned to all stocks and registered bonds in the United States and Canada. CUSIP 'netting' is the practice whereby the balance of a security held by an entity is reduced by the balance of that same security which the entity has sold, but not yet purchased, a so-called 'short sale'. This practice is applied to ensure that the entity properly reflects its security positions and does not reflect a financial liability to repurchase a security when in fact there is no such obligation. This is based on the definition of a financial liability held for trading which includes "obligations to deliver financial assets borrowed by a short seller (ie an entity that sells financial assets it has borrowed **and does not yet own**)" (emphasis added).

[IFRS 9.BA.7].

This practice is based on the assumption that securities with the same CUSIP number are fungible, and therefore, it would not be appropriate to present a long and a short position for the same security. This practice is equally applicable to securities with the same ISIN number, a unique identification number used in other markets.

How we see it

While the practice is referred to as netting, in our view, this is really a recognition question - is it appropriate to recognise long and short positions in the same security at the reporting date? In principle, this is different from the offsetting of separate financial assets and financial liabilities when the offsetting rules within IAS 32.42 to 50 are met as discussed in Chapter 50.

In our view, this practice is generally appropriate, i.e., the long and short positions may be derecognised, particularly where the securities are managed within the same pool of financial assets and financial liabilities, for example where internal security lending arrangements are in place to cover short positions, and both the long and short positions are classified under IFRS 9 as at fair value through profit or loss. Therefore, derecognition is appropriate when securities are managed together within the same trading book.

Where securities are not managed together, for example where the long position is held in the banking book and there is no intention of using this to settle a short position held in the trading book, it would be more challenging to achieve derecognition. In this situation the long position may be classified as at amortised cost or at fair value through other comprehensive income (see Chapter 44) and derecognition based on a matching with trading short sale positions would seem to bring into question the business model conclusion. Short sale liabilities are part of the trading liabilities and the reference in the definition to the sale by an entity of "financial assets it has borrowed and does not yet own" would suggest that the focus is on the financial assets also held for trading.

8 Client money

A number of financial institutions and other entities hold money on behalf of clients. The terms on which such money is held can vary widely. In the case of normal deposits with a bank, the bank is free to use the client's money for its own purposes, with the client being protected by the capital requirements imposed by the regulatory authorities. By contrast there are cases (e.g., in the case of certain monies held by legal advisers on behalf of their clients in some jurisdictions) where funds held on behalf of clients must be kept in a bank account completely separate from that of the depositary entity itself, with all interest earned on the account being for the benefit of clients. There are also intermediate situations where, for example:

- Funds are required to be segregated in separate bank accounts but the depositary entity is allowed to retain some or all of the interest on the client accounts.

Or

- Client funds are allowed to be commingled with those of the depositary entity, but some or all income on the funds must be passed on to clients.

This raises the question of how client monies shall be accounted for in the financial statements prepared in accordance with IFRS accounting standards. There is no specific guidance available and, as a result, it needs to be determined whether the client monies meet the definition of an asset from the Conceptual Framework. In particular, whether the funds are a present economic resource controlled by the entity and have the potential to create future economic benefits [CF 4.3, CF 4.4].

If the entity concludes that the client money should be recognised as an asset, in the absence of specific guidance, the rules for the treatment of funds received under a pass-through arrangement (see section 3.6.2 above) shall be applied.

The types of arrangement to deal with client money are so varied that it is impossible to generalise as to the appropriate treatment. Key considerations include:

- Which party is at risk from the failure of assets, such as bank accounts, in which the client money is held
- The status of the funds in the event of the insolvency of either the reporting entity or its client
- Whether the reporting entity can use the cash for its own purposes as opposed to administering the cash on behalf of the client in its capacity as an agent

And

- Which party has the benefit of income from the assets

The analysis for the two extreme cases seems relatively straightforward. In the case of a bank deposit (or any arrangement where the entity may freely use client cash for its own benefit), the general recognition criteria of IFRS 9 indicate that an asset and a liability shall be recognised. Conversely, where the entity is required to hold funds on behalf of clients in a bank account completely separate from the entity's own funds, with all interest earned on the account being kept for the benefit of clients, it is hard to see how such funds meet the general definition of an asset under the *Conceptual Framework for Financial Reporting*. Whilst the entity administers such funds in its capacity as an agent on behalf of the client, it can derive no economic benefits from them. The intermediate cases may be harder to deal with.

Sometimes the appropriate analysis will be that the depositary entity enjoys sufficient use of the client money that it must be recognised as an asset with a corresponding liability due to the client. This will be the case, for example, if the client money is commingled with the reporting entity's cash for a short period of time. During this period the reporting entity is exposed to the credit risk associated with the cash and is entitled to all income accruing. Hence, the reporting entity would recognise the cash as an asset and a corresponding liability. If the cash is later moved to a segregated client trust account, an analysis must be performed to determine whether or not the cash and the corresponding liability have to be derecognised from the reporting entity's statement of financial position.

9 Current and future developments

9.1 Modification of financial assets and liabilities

During the PIR of IFRS 9 - Classification and Measurement, the IASB decided not to immediately address feedback received in relation to modification of financial assets and liabilities. Instead, it decided to add a standard-setting project to its research pipeline to clarify the requirements in IFRS 9 at a later stage, namely the 'Amortised Cost Measurement Project'.²¹

The feedback indicated that many respondents consider that the current guidance should be supplemented by further clarifications and additional application guidance. They also expressed a concern about a lack of a clear principle on how to determine when modifications of financial assets result in derecognition, leading to diversity in practice, including significant application, audit and enforcement challenges. Further, it was noted that the requirements in IFRS 9 5.4.3 are less specific than the comparable requirements for financial liabilities.

Similarly, when the IASB received feedback on the interaction between the modification guidance and various components of the impairment model for financial assets during the Post-Implementation Review of IFRS 9 - Impairment, it decided not to address these issues as part of the PIR but consider these as part of the Amortised Cost Measurement Project.²²

On 16 June 2025, the IASB decided to move the Amortised Cost Measurement project to the standard-setting work plan.²³ An exposure draft is expected in the second half of 2026.

Appendix B - Defined terms

Extract from IFRS standards - Definitions

derecognition	The removal of a previously recognised financial asset or financial liability from an entity's statement of financial position. <i>[IFRS 9 Appendix A].</i>
derivative	<p>A financial instrument or other contract within the scope of this Standard with all three of the following characteristics.</p> <ul style="list-style-type: none"> (a) its value changes in response to the change in a specified interest rate, financial instrument price, commodity price, foreign exchange rate, index of prices or rates, credit rating or credit index, or other variable, provided in the case of a non-financial variable that the variable is not specific to a party to the contract (sometimes called the 'underlying'). (b) it requires no initial net investment or an initial net investment that is smaller than would be required for other types of contracts that would be expected to have a similar response to changes in market factors. (c) it is settled at a future date. <i>[IFRS 9 Appendix A].</i>
fair value	The price that would be received to sell an asset or paid to transfer a liability in an orderly transaction between market participants at the measurement date. <i>[IFRS 13 Appendix A].</i>
financial asset	<p>A financial asset is any asset that is:</p> <ul style="list-style-type: none"> (a) cash; (b) an equity instrument of another entity; (c) a contractual right: <ul style="list-style-type: none"> (i) to receive cash or another financial asset from another entity; or (ii) to exchange financial assets or financial liabilities with another entity under conditions that are potentially favourable to the entity; or (d) a contract that will or may be settled in the entity's own equity instruments and is: <ul style="list-style-type: none"> (i) a non-derivative for which the entity is or may be obliged to receive a variable number of the entity's own equity instruments; or (ii) a derivative that will or may be settled other than by the exchange of a fixed amount of cash or another financial asset for a fixed number of the entity's own equity instruments. <p>For this purpose the entity's own equity instruments do not include puttable financial instruments classified as equity instruments in accordance with paragraphs 16A and 16B, instruments that impose on the entity an obligation to deliver to another party a pro rata share of the net assets of the entity only on liquidation and are classified as equity instruments in accordance with paragraphs 16C and 16D, or instruments that are contracts for the future receipt or delivery of the entity's own equity instruments. <i>[IAS 32.11].</i></p>
financial guarantee contract	A contract that requires the issuer to make specified payments to reimburse the holder for a loss it incurs because a specified debtor fails to make payment when due in accordance with the original or modified terms of a debt instrument. <i>[IFRS 9 Appendix A].</i>
financial instrument	A financial instrument is any contract that gives rise to a financial asset of one entity and a financial liability or equity instrument of another entity. <i>[IAS 32.11].</i>

financial liability

A *financial liability* is any liability that is:

- (a) a contractual obligation:
 - (i) to deliver cash or another financial asset to another entity; or
 - (ii) to exchange financial assets or financial liabilities with another entity under conditions that are potentially unfavourable to the entity; or
- (b) a contract that will or may be settled in the entity's own equity instruments and is:
 - (i) a non-derivative for which the entity is or may be obliged to deliver a variable number of the entity's own equity instruments; or
 - (ii) a derivative that will or may be settled other than by the exchange of a fixed amount of cash or another financial asset for a fixed number of the entity's own equity instruments. For this purpose, rights, options or warrants to acquire a fixed number of the entity's own equity instruments for a fixed amount of any currency are equity instruments if the entity offers the rights, options or warrants pro rata to all of its existing owners of the same class of its own non-derivative equity instruments. Also, for these purposes the entity's own equity instruments do not include puttable financial instruments that are classified as equity instruments in accordance with paragraphs 16A and 16B, instruments that impose on the entity an obligation to deliver to another party a pro rata share of the net assets of the entity only on liquidation and are classified as equity instruments in accordance with paragraphs 16C and 16D, or instruments that are contracts for the future receipt or delivery of the entity's own equity instruments.

As an exception, an instrument that meets the definition of a financial liability is classified as an equity instrument if it has all the features and meets the conditions in paragraphs 16A and 16B or paragraphs 16C and 16D. [IAS 32.11].

modification gain or loss

The amount arising from adjusting the **gross carrying amount of a financial asset** to reflect the renegotiated or modified contractual cash flows. The entity recalculates the gross carrying amount of a financial asset as the present value of the estimated future cash payments or receipts through the expected life of the renegotiated or modified financial asset that are discounted at the financial asset's original **effective interest rate** (or the original **credit-adjusted effective interest rate** for **purchased or originated credit-impaired financial assets**) or, when applicable, the revised **effective interest rate** calculated in accordance with paragraph 6.5.10. When estimating the expected cash flows of a financial asset, an entity shall consider all contractual terms of the financial asset (for example, prepayment, call and similar options) but shall not consider the **expected credit losses**, unless the financial asset is a **purchased or originated credit-impaired financial asset**, in which case an entity shall also consider the initial expected credit losses that were considered when calculating the original **credit-adjusted effective interest rate**. [IFRS 9 Appendix A].

transaction costs

Incremental costs that are directly attributable to the acquisition, issue or disposal of a financial asset or financial liability (see paragraph B5.4.8). An incremental cost is one that would not have been incurred if the entity had not acquired, issued or disposed of the financial instrument. [IFRS 9 Appendix A].

Chapter 49

Financial instruments: Hedge accounting

Contents

Overview	4083
1 Introduction	4084
1.1 Background	4084
1.2 What is hedge accounting?	4084
1.3 Development of hedge accounting standards	4085
1.4 Objective of hedge accounting	4086
1.5 Hedge accounting overview	4087
2 Hedged items	4089
2.1 General requirements	4089
2.2 Risk components	4090
2.2.1 General requirements	4090
2.2.2 Contractually specified risk components	4091
2.2.3 Non-contractually specified risk components	4092
2.2.3.A Non-contractual risk components in financial instruments	4092
2.2.3.B Non-contractual risk components in non-financial instruments	4093
2.2.4 Partial term hedging	4095
2.2.5 Foreign currency as a risk component	4096
2.2.6 Inflation as a risk component	4098
2.2.7 Interest rate risk component in an insurance contract	4100
2.3 Components of a nominal amount	4101
2.3.1 General requirement	4101
2.3.2 Layer component for fair value hedges with prepayment risk	4103
2.4 The 'sub-benchmark rate issue'	4106
2.4.1 Late hedges of benchmark rate portions of fixed rate instruments	4108
2.4.2 Negative interest rates	4109
2.5 Groups of items	4111
2.5.1 General requirements	4111
2.5.2 Hedging a component of a group	4111
2.5.3 Cash flow hedge of a net position	4112
2.5.4 Nil net positions	4115

2.6	Other eligibility issues for hedged items	4115
2.6.1	Highly probable	4115
2.6.2	Hedged items held at fair value through profit or loss	4117
2.6.2.A	Hedged items managed on a fair value basis	4118
2.6.2.B	Hedged items held for trading	4119
2.6.2.C	Hedged items that have failed the contractual cash flows test	4119
2.6.3	Hedges of exposures affecting other comprehensive income	4119
2.6.4	Hedges of a firm commitment to acquire a business	4119
2.6.5	Forecast acquisition or issuance of foreign currency monetary items	4120
2.6.6	Own equity instruments	4120
2.6.7	Core deposits	4120
2.6.8	Leases and associated right-of-use assets	4121
2.6.9	Hedge accounting for associates	4123
2.7	Aggregated exposures	4123
2.7.1	Introduction	4123
2.7.2	Background	4123
2.7.3	Accounting for aggregated exposures	4125
2.7.3.A	Cash flow hedge of an aggregated exposure of foreign currency fixed rate loan and cross-currency interest rate swap	4126
2.7.3.B	Fair value hedge of an aggregated exposure of foreign currency floating rate loan and cross-currency swap interest rate swap	4128
2.7.3.C	Cash flow hedge of an aggregated exposure of coffee purchases and benchmark price coffee forward contract	4129
2.7.3.D	Cash flow hedge of an aggregated exposure of forecast foreign currency debt and forecast cross-currency swap interest rate swap	4131
2.7.3.E	Cash flow hedge of an aggregated exposure of a net investment in a foreign operation and cross-currency swap interest rate swap	4131
3	Hedging instruments	4132

Overview

This chapter discusses the hedge accounting requirements of IFRS 9 *Financial instruments*.

Most entities undertake some form of risk management, often using derivatives for that purpose. The hedge accounting requirements of IFRS 9 provide additional accounting guidance where financial instruments are transacted for the purpose of risk management. Application of the hedge accounting requirements is voluntary but is often desirable, as the normal IFRS accounting standards might not reflect the risk management in the statement of financial position and/or the statement of profit or loss and other comprehensive income.

This chapter deals with the various criteria that must be met in order to apply hedge accounting, as well as the associated accounting when hedge accounting is applied.

Although entities are still permitted to apply the hedge accounting requirements of IAS 39 *Financial Instruments: Recognition and Measurement*, this chapter only covers the hedge accounting requirements of IFRS 9 in any detail. A summary of the main differences between the IFRS 9 and IAS 39 hedge accounting requirements is however provided.

There are three permitted types of hedge relationships: a fair value hedge, a cash flow hedge and the hedge of a net investment in a foreign operation. In order to apply hedge accounting the hedge relationship must be formally documented up front and must include only eligible hedged item(s) and hedging instrument(s).

The qualification criteria for the application of hedge accounting must be met at inception of the hedge relationship and on an ongoing basis. They include:

- There is an economic relationship between the hedged item(s) and the hedging instrument(s)
- The effect of credit risk does not dominate the value changes that result from that economic relationship
- And
- An appropriate hedge ratio is used

Further, any hedge designation must be directionally consistent with actual risk management.

The application of hedge accounting is incremental to the usual treatment for the hedged item and/or hedging instrument in accordance with IFRS accounting standards. The accounting treatment of financial instruments as required by IFRS 9 is dealt with in earlier chapters. In particular, Chapter 42 deals with derivatives and embedded derivatives and Chapter 46 deals with the subsequent measurement of financial instruments.

The accounting entries for the application of hedge accounting are driven by the change in fair value of the hedging instrument and the change in present value of the hedged item. There is an expectation that such changes in value will largely offset, however to the extent this is not the case, it is likely to result in hedge ineffectiveness being recorded in profit or loss.

What you need to know

- Hedge accounting changes either the accounting for the hedged item or the hedging instrument in order to better represent an entity's risk management activities in the financial statements. It is a requirement that any hedge designations are directionally consistent with the entity's actual risk management.
- This is not to say that in all cases it will be possible to fully reflect risk management, given the strict criteria for application of hedge accounting, such as what qualifies as a hedging instrument or a hedged item to achieve hedge accounting. Meeting the criteria for both the initial and ongoing application of hedge accounting can be complex, in particular where risks have only partially been mitigated.
- The application of hedge accounting is driven by the hedge documentation and can only be applied prospectively. The use of hindsight is not permitted.
- Although the application of hedge accounting may reduce levels of profit or loss volatility from instruments transacted for risk management purposes, such as derivatives, it does not always follow that profit or loss volatility will be eliminated completely. It depends on the existence of any sources of ineffectiveness within the hedge relationship.
- Although the initial application of the hedge accounting requirements is a choice, once that choice is made for a particular transaction it must continue to be applied until the specific criteria for discontinuation are met. Discontinuation of hedge accounting is prospective only.

1 Introduction

1.1 Background

Chapter 40 provides a general background to the development of accounting for financial instruments and notes the fundamental changes that have been experienced in international financial markets. The markets for derivatives, especially, have seen remarkable and continued growth over the past four decades. This reflects the increasing use of such instruments by businesses, commonly to 'hedge' their financial risks. Accordingly, the accounting treatment for derivatives and hedging activities has taken on a high degree of importance.

'Hedging' itself is a much wider topic than hedge accounting and is not the primary subject of this chapter. It is an imprecise term although standard setters frequently describe hedging in terms of designating a hedging instrument that has a value that is expected, wholly or partly, to offset changes in the value or cash flows of a 'hedged position'. In this context, hedged positions normally include those arising from recognised assets and liabilities, contractual commitments and expected, but uncontracted, future transactions. Whilst this could be an appropriate description for many hedges, it does not necessarily capture the essence of all risk management activities involving financial instruments. Nevertheless, it forms the basis for the hedge accounting requirements under IFRS accounting standards.

Differences between the IFRS accounting standards and US GAAP guidance on this topic are not addressed in this chapter as the standards are not converged. Therefore, differences between IFRS accounting standards and US GAAP will exist that are not discussed in this chapter.

1.2 What is hedge accounting?

Every entity is exposed to business risks from its daily operations. Many of those risks have an impact on the cash flows or the value of assets and liabilities, and therefore, ultimately affect profit or loss. In order to manage these risk exposures, companies often enter into derivative contracts (or, less commonly, other financial instruments) to hedge them. Hedging can therefore be seen as a risk management activity in order to change an entity's risk profile.

Applying the default IFRS accounting standards requirements to those risk management activities can result in accounting mismatches when the gains or losses on a hedging instrument are not recognised in the same period(s) and/or in the same place in the financial statements as gains or losses on the hedged exposure. Many believe that the resulting accounting mismatches are not a good representation of those risk management activities. Hedge accounting is often seen as 'correcting' deficiencies in the accounting requirements that would otherwise apply to each leg of the hedge relationship. These deficiencies are an inevitable consequence of using a mixed-measurement model of accounting. Typically, hedge accounting involves recognising gains and losses on a hedging instrument in the same period(s) and in the same place in the financial statements as gains or losses on the hedged position. It could be used in a number of situations, for example to adjust (or correct) for:

Measurement differences

These might arise where the hedge is of a recognised asset or liability that is measured on a different basis to the hedging instrument. An example might be inventory that is recorded in the financial statements at cost, but whose value is hedged by a forward contract that enables inventory of the same nature to be sold at a predetermined price. In this case, both the hedging instrument and the hedged position exist and are recognised in the financial statements, but they are likely to be measured on different bases.

Avoiding the measurement difference could, in this situation, theoretically be achieved in a number of ways. One alternative would be not to recognise unrealised gains or losses on the forward contract, and for realised gains or losses to be deferred (e.g., separately as assets or liabilities or by including them within the carrying amount of the inventory) until the inventory is sold. On the other hand, if unrealised gains or losses on the forward contract were recognised in profit or loss, the measurement basis of the inventory could be changed to reflect changes in its fair value in profit or loss. (See sections 5.1 and 5.2 below for discussion of the permitted designations under IFRS 9).

Performance reporting differences

Even if the measurement bases of the hedging instrument and hedged item are the same, performance reporting differences might arise if gains and losses are reported in a different place in the financial statements. An example might be where an investment in shares is classified as fair value through other comprehensive income (FVOCI) (see Chapter 44) and whose value is hedged by a put option. The investment and the put option are both measured at fair value. However, gains or losses on the investment are recognised in other comprehensive income whilst those on the put option are recognised in profit or loss, therefore resulting in a mismatch in the income statement (or statement of comprehensive income). Similarly, gains or losses on retranslating the net assets of a foreign operation are recorded in other comprehensive income whilst retranslation gains or losses on a foreign currency borrowing used to hedge that net investment are, absent any form of hedge accounting, recorded in profit or loss.

In the case of the FVOCI investment and the put option, hedge accounting might involve reporting gains and losses on the investment in profit or loss, or gains and losses on the put option in other comprehensive income. For the foreign operation, hedge accounting normally involves reporting the retranslation gains and losses on both the borrowing and the foreign operation in other comprehensive income. (See sections 5.3, 7.3 and 7.8 below for discussion of the permitted designations under IFRS 9).

Recognition differences

These might arise where the hedge is of contractual rights or obligations that are not recognised in the financial statements. An example is a foreign currency denominated operating lease held by the lessor, where the unrecognised future contractual lease rentals to be received in another currency are hedged by a series of forward currency contracts (i.e., each receipt is effectively 'fixed' in functional currency terms).

In this case, one solution might be to treat the lease as a 'synthetic' functional currency denominated lease. A similar outcome would be obtained if unrealised gains and losses on each forward contract remained unrecognised or deferred until the accrual of the lease receivables it was hedging. (See section 5.2 below for discussion of the permitted designation under IFRS 9).

Existence differences

These might arise where the hedge is of cash flows arising from an uncontracted future transaction, i.e., a transaction that does not yet exist. An example is a foreign currency denominated sale expected next year that is hedged by a forward currency contract.

Again, a solution to this issue might involve treating the future sale as a 'synthetic' functional currency sale, deferring the gain or loss on the forward contract until the sale is recognised in profit or loss or it might involve not recognising the forward contract until it is settled. (See section 5.2 below for discussion of the permitted designation under IFRS 9).

1.3 Development of hedge accounting standards

The first comprehensive hedge accounting requirements issued by the IASB were contained in IAS 39. Hedge accounting under IAS 39 was often criticised as being complex and rules-based, and thus, ultimately not reflecting an entity's risk management activities. This was unhelpful for preparers and users of the financial statements alike. The IASB took this concern as the starting point of its project for a new hedge accounting model. Consequently, the objective of IFRS 9 is to reflect the effect of an entity's risk management activities in the financial statements. [IFRS 9.6.1.1].

In addition, the financial crisis resulted in a significant amount of political pressure being brought to bear on standard setters in general and the IASB specifically. Responding to this pressure, in April 2009 the IASB announced a detailed six-month timetable for publishing a proposal to replace IAS 39. In order to expedite the replacement of IAS 39, the IASB divided the project into three phases: classification and measurement; amortised cost and impairment of financial assets; and hedge accounting.

In December 2010, the IASB issued the Exposure Draft ('ED' or the exposure draft) *Hedge Accounting*, being the proposals for the third part of IFRS 9. After redeliberating the proposals in 2011, in September 2012 the Board published a draft of *Chapter 6 - Hedge Accounting* - of IFRS 9, together with consequential changes to other parts of IFRS 9 and other IFRS accounting standards (the draft standard). The idea of the draft standard was to enable constituents to familiarise themselves with the new requirements.

Although the IASB did not ask for comments, a number of constituents asked the IASB to clarify certain elements of the draft standard. As a result, the IASB redeliberated some elements of the IFRS 9 hedge accounting requirements in its January 2013 and April 2013 meetings.

This resulted in the third version of IFRS 9, issued in November 2013, which included the new hedge accounting requirements. Finally, in July 2014 the IASB issued the all-encompassing final version of IFRS 9 that includes the new impairment requirements (see Chapter 47) and some amendments to the classification and measurement requirements (see Chapters 44 to Chapter 46). This also involved some minor consequential amendments to the hedge accounting requirements in IFRS 9, mainly because of the introduction of a new category for debt instruments measured at fair value through other comprehensive income with subsequent reclassification adjustments.

IFRS 9 does not provide any particular solutions for so-called 'macro hedge' accounting, the term used to describe the more complex risk management practices used by entities such as banks to manage risk in dynamic portfolios. In May 2012 the Board decided to decouple accounting for macro hedging from IFRS 9, and a separate project was set up to develop an accounting solution for dynamic risk management - the project name adopted by the IASB for an accounting solution for macro hedging. Work is still ongoing for the Dynamic Risk Management project. A discussion paper - *Accounting for Dynamic Risk Management: a Portfolio Revaluation Approach to Macro Hedging* - was published in April 2014. No consensus was reached as a result of the discussion paper. The IASB has continued to work on developing a new accounting model for dynamic risk management and we expect the IASB to issue an Exposure Draft on the DRM model in December 2025 (at time of writing). See section 10.1 below for more details.

IFRS 9 is effective for periods beginning on or after 1 January 2018 and replaces substantially all of IAS 39, including the hedge accounting requirements. However, given the fact IFRS 9 does not include an accounting solution for dynamic risk management, entities are permitted an accounting policy choice to continue applying the hedge accounting requirements of IAS 39 instead of those in IFRS 9. [IFRS 9.7.2.21]. See section 10.2 below.

Furthermore, for a fair value hedge of the interest rate exposure of a portfolio of financial assets or financial liabilities (and only for such a hedge), an entity may apply the related hedge accounting requirements in IAS 39 instead of those in IFRS 9. This choice relates only to a fair value portfolio hedge as described in IAS 39.81A and 89A and IAS 39.AG114 to AG132 (see section 10.2 below). [IFRS 9.6.1.3]. A decision to continue to apply this IAS 39 guidance is not part of the accounting policy choice to defer IAS 39 mentioned above.

This chapter focuses on the hedge accounting requirements of IFRS 9. The main differences between hedge accounting under IFRS 9 and the hedge accounting requirements in IAS 39 are discussed in section 13 below.

In developing IFRS 9, the IASB decided not to carry forward any of the hedge accounting related Implementation Guidance that accompanied IAS 39. However, the IASB emphasised that not carrying forward the Implementation Guidance did not mean that it had rejected the guidance. Implementation Guidance only accompanies, but is not part of, the standard. [IFRS 9.BC6.93, IFRS 9.BC6.94, IFRS 9.BC6.95]. An entity might have relied on particular Implementation Guidance in IAS 39 as an interpretation of the IAS 39 hedge accounting guidance. Accordingly, in many instances, the entity could also interpret the same outcome based on the IFRS 9 hedge accounting guidance - in the absence of contradicting guidance within IFRS 9. Hence much of the Implementation Guidance in IAS 39 remains relevant for the application of IFRS 9.

Accordingly, whilst this chapter predominantly focuses on the guidance included with IFRS 9, on occasion IAS 39 Implementation Guidance is included where this is considered to be relevant and helpful.

1.4 Objective of hedge accounting

The objective of the IFRS 9 hedge accounting requirements is to "represent, in the financial statements, the effect of an entity's risk management activities". The aim of the objective is "to convey the context of hedging instruments for which hedge accounting is applied in order to allow insight into their purpose and effect". [IFRS 9.6.1.1]. This is achieved by reducing the accounting mismatch by changing either the measurement or (in the case of certain firm commitments) recognition of the hedged exposure, or the accounting for the hedging instrument, but with some important improvements when compared to IAS 39.

This is a rather broad objective that focuses on an entity's risk management activities and reflects what the Board wanted to achieve with the new accounting requirements. However, this broad objective does not override any of the hedge accounting requirements, which is why the Board noted that hedge accounting is only permitted if all the new qualifying criteria are met (see section 6 below). [IFRS 9.BC6.82].

1.5 Hedge accounting overview

Given the stated objective of IFRS 9 is for hedge accounting to represent an entity's risk management activities where possible, the first step in achieving hedge accounting under IFRS 9 is to identify the relevant risk management strategy and the objective for a particular hedge relationship. These form the foundations for hedge accounting under IFRS 9 (see section 6.2 below).

The standard defines three types of hedge relationships: [IFRS 9.6.5.2]

Extract from IFRS 9

6.5.2 There are three types of hedging relationships:

- (a) **fair value hedge:** a hedge of the exposure to changes in fair value of a recognised asset or liability or an unrecognised firm commitment, or a component of any such item, that is attributable to a particular risk and could affect profit or loss.
- (b) **cash flow hedge:** a hedge of the exposure to variability in cash flows that is attributable to a particular risk associated with all, or a component of, a recognised asset or liability (such as all or some future interest payments on variable-rate debt) or a highly probable forecast transaction, and could affect profit or loss.
- (c) **hedge of a net investment in a foreign operation** as defined in IAS 21.

[IFRS 9.6.5.2].

Each of these are discussed in turn below (fair value hedges in section 5.1, cash flow hedges in section 5.2, and hedges of a net investment in a foreign operation in section 5.3).

An entity may choose to designate a hedging relationship between a hedging instrument and a hedged item in order to achieve hedge accounting. [IFRS 9.6.1.2]. Prior to hedge accounting being applied, all of the following steps must have been completed:

- Identification of eligible hedged item(s) and hedging instrument(s) (see sections 2 and 3 below)
- Identification of an eligible hedged risk (see section 2.2 below)
- Ensuring the hedge relationship meets the definition of one of the permitted types (a fair value, cash flow or net investment hedge) (see section 5 below)
- Satisfying the qualifying criteria for hedge accounting (see section 6 below)

And

- Formal designation of the hedge relationship (see section 6.3 below)

Once these requirements are met, hedge accounting can be applied prospectively, but the ongoing qualifying criteria and assessments must continue to be met, otherwise hedge accounting will cease. (See section 8 below).

The table below summarises the application of hedge accounting for the three types of hedge relationships:

Figure 1-1: Accounting for hedge relationships

Hedge type	Fair value	Cash flow	Net investment
Hedged item	Carrying amount adjusted for changes in fair value with respect to the hedged risk. Adjusted through profit or loss. (1) (2)	N/A	N/A
Hedging instrument	N/A (2)	No change to carrying amount, but effective portion of change in fair value is recorded in OCI.	No change to carrying amount, but effective portion of change in fair value is recorded in OCI.
Resultant profit or loss	Ineffective portion (2)	Ineffective portion	Ineffective portion

(1) For debt instruments measured at FVOCI, the carrying amount of the hedged item is not adjusted through fair value hedge accounting. However, the changes in fair value with respect to the hedged risk are recorded in P/L instead of OCI.

(2) For equity instruments for which the option to present fair value changes in FVOCI has been taken, the carrying amount of the hedged item is not adjusted through fair value hedge accounting. Changes in fair value remain presented in OCI but the gain or loss on the hedging instruments is recognised in OCI. The ineffective portion of the hedge is also presented in OCI.

As it can be seen from the above, for a fair value hedge, an adjustment is made to the carrying value of the hedged item to reflect the change in value due to the hedged risk, with an offset to profit or loss for the change in value of the hedging instrument. Where the offset is not complete, this will result in ineffectiveness to be recorded in profit or loss (see section 7.4 below).

However, for both a cash flow and net investment hedge, the carrying amount of the hedged item, which for a cash flow hedge might not even yet be recognised, is unchanged. The effect of hedge accounting is to defer the effective portion of the change in value of the hedging instrument in other comprehensive income. Any ineffective portion will remain in profit or loss as ineffectiveness.

See section 7 below for more details on accounting for eligible hedges.

2 Hedged items

2.1 General requirements

The basic requirement for a hedged item is for it to be one of the following:

- A recognised asset or liability
- An unrecognised firm commitment
- A highly probable forecast transaction

Or

- A net investment in a foreign operation

The hedged item must be reliably measurable and can be a single item, or a group of items (see section 2.5 below). A hedged item can also be a component of such an item(s) (see sections 2.2 and 2.3 below).

[IFRS 9.6.3.1, IFRS 9.6.3.2, IFRS 9.6.3.3].

Recognised assets and liabilities can include financial items and non-financial items such as inventory. Most internally-generated intangibles (e.g., for a bank, a core deposit intangible - see section 2.6.7 below) are not recognised assets and therefore cannot be hedged items. However, firm commitments that are not routinely recognised as assets or liabilities absent the effects of hedge accounting for such items, can be eligible hedged items. This would include loan commitments (see Chapter 41). [IFRS 9.6.3.1].

The term 'highly probable' is not defined in IFRS 9 but is often interpreted to mean a much greater likelihood of happening than 'more likely than not'. The Implementation Guidance within IAS 39 contained some guidance as to how the term highly probable is applied within the context of hedge accounting. This guidance can be considered relevant for IFRS 9 hedge accounting (see section 2.6.1 below).

A net investment in a foreign operation is defined in paragraph 8 of IAS 21 *The Effects of Changes in Foreign Exchange Rates* - to be the amount of the reporting entity's interest in the net assets of that operation (see Chapter 16) (see section 5.3.2 below).

An aggregated exposure that is a combination of an exposure that could qualify as a hedged item and a derivative may also be designated as a hedged item (see section 2.7 below). [IFRS 9.6.3.4].

Only assets, liabilities, firm commitments and forecast transactions with an external party qualify for hedge accounting. [IFRS 9.6.3.5]. As an exception, a hedge of the foreign currency risk of an intragroup monetary item qualifies for hedge accounting if that foreign currency risk affects consolidated profit or loss (see section 4.3.1 below). In addition, the foreign currency risk of a highly probable forecast intragroup transaction would also qualify as a hedged item if that transaction affects consolidated profit or loss.

[IFRS 9.6.3.6]. (See section 4.3.2 below).

In the case of a financial liability containing an embedded derivative (see Chapter 42), if the embedded derivative is accounted for separately from the host instrument, the hedged item would be the host instrument or components thereof, without regard for the embedded derivative (see sections 2.2 and 2.3 below); basing it on the hybrid instrument (i.e., the instrument including the embedded derivative) or the cash flows from the hybrid is not permitted. This is because derivatives are only permitted as a hedged item as part of an eligible aggregated exposure (see section 2.7 below).

An entity can designate an item in its entirety or a component of an item as the hedged item in a hedging relationship. An entire item comprises all changes in the cash flows or fair value of an item. A component comprises less than the entire fair value change or cash flow variability of an item. In that case an entity may designate only the following types of components (including combinations) as hedged items:

- Changes in the cash flows or fair value of an item attributable to a specific risk or risks (i.e., a risk component), including one sided risks (see section 2.2 below)
- One or more selected contractual cash flows

And

- Components of a nominal amount, i.e., a specified part of the amount of an item (see section 2.3 below) [IFRS 9.6.3.7]

As noted, it is possible to designate a combination of eligible types of components as the hedged item. For example, in a fair value hedge of interest rate risk of a financial asset receiving a fixed rate coupon, it would be possible to designate 50% of the financial asset only for changes in the fair value with respect to a benchmark interest rate. This reflects a hedged item identified by a combination of both a nominal and a risk component, other combinations are also possible.

The reference to one sided risks refers to an ability to designate only changes in the cash flows or fair value of a hedged item above or below a specified price or other variable, or only changes within a specified hedged range. The intrinsic value of a purchased option hedging instrument (assuming that it has the same principal terms as the designated risk), but not its time value, reflects a one-sided risk in a hedged item. For example, an entity can designate the variability of future cash flow outcomes resulting from a price increase of a forecast commodity purchase, without including the risk of a price decrease within the hedge relationship. Such a situation could arise if the entity wanted to retain the opportunity to benefit from a lower commodity price, but protect itself against an increase by buying a call option. In such a situation, only cash flow losses that result from an increase in the price above the specified level are designated. The hedged risk does not include the time value of the purchased option (see section 3.6.4 below).

[IFRS 9.6.3.7(a)].

Only the portion of cash flows or fair value of a financial instrument that is designated as the hedged item are subject to the hedge accounting requirements. The accounting for other portions that are not designated as the hedged item remains unchanged. [IFRS 9.B6.3.11].

The guidance also adds that to be eligible for hedge accounting, a risk component must be a separately identifiable component of the financial or non-financial item, and the changes in the cash flows or fair value of the item attributable to changes in that risk component must be reliably measurable. [IFRS 9.B6.3.8]. This is considered further in section 2.2 below.

There is no requirement to designate a hedged item only on initial recognition. Designation of hedged items sometime after their initial recognition (e.g., after a previous hedge relationship is discontinued) is permitted if consistent with an entity's risk management activities, although some additional complexity could arise when identifying risk components (see section 2.4.1 below). [IFRS 9.B6.5.28].

2.2 Risk components

2.2.1 General requirements

Instead of hedging the total changes in fair values or cash flows, risk managers often enter into derivatives to hedge only specific risk components. Managing a specific risk component reflects that hedging all risks is often not economical and hence not desirable, or even not possible (because of a lack of suitable hedging instruments).

If designated, the usual hedge accounting requirements apply to a risk component in the same way as they apply to other hedged items that are not risk components. For example, the qualifying criteria apply, including that the hedging relationship must meet the hedge effectiveness requirements, and any hedge ineffectiveness must be measured and recognised, albeit only with respect to the hedged risk, and not the full item (see sections 6 and 7.4 below). [IFRS 9.B6.3.11, IFRS 9.B6.4.1].

IFRS 9 permits an entity to designate a risk component of a financial or non-financial item as the hedged item in a hedging relationship. Designation of a risk component means that only changes in the cash flows or fair value of the hedged item with respect to the designated risk are subject to the hedge accounting requirements. So instead of considering value changes in the hedged item with respect to all risks that are value drivers, only value changes in the hedged item with respect to the designated risk component are considered for hedge accounting purposes. This is valuable as it is common for entities to economically hedge a specific risk within a hedged item rather than its full price risk. The ability to designate risk components in a hedge relationship is an important step in enabling entities to achieve the IASB's objective for hedge accounting, which is to "represent, in the financial statements, the effect of an entity's risk management activities". [IFRS 9.6.1.1].

It should be noted, however, that only eligible risk components can be designated in hedge relationships. IFRS 9 provides guidance on this topic which is discussed in the sections below.

The key requirements for designating a risk component are that:

- A risk component is less than the entire item (see section 2.4 below)
 - It must be a separately identifiable component of the item
- And
- The changes in the cash flows or fair value of the item attributable to the changes in that risk component must be reliably measurable [IFRS 9.B6.3.7, IFRS 9.B6.3.8]

A risk component can be contractually specified in the contract (see section 2.2.2 below) but non-contractually specified risk components could also be eligible (see section 2.2.3 below). [IFRS 9.B6.3.10].

The IFRS 9 guidance requires that when identifying what risk components qualify for designation as a hedged item, in particular whether they are separately identifiable and reliably measurable, an entity assesses such risk components within the context of the particular market structure to which the risk(s) relate and in which the hedging activity takes place. [IFRS 9.B6.3.9]. However, this assessment is particularly relevant for non-contractual risk components, for which it is important to undertake a careful analysis of the specific facts and circumstances of the relevant markets. [IFRS 9.BC6.176].

As noted above, a risk component could be contractually specified, or it could be implicit in the fair value or the cash flows of the item to which the component belongs. [IFRS 9.B6.3.10]. However, the mere fact that a physical component is part of the make-up of the whole item does not mean that the component necessarily qualifies as a risk component for hedge accounting purposes. A physical component is neither required nor by itself sufficient to meet the criteria for risk components that are eligible as a hedged item. However, depending on the relevant market structure, a physical component can help meet those criteria. The example of an eligible risk component that is often quoted is that of the crude oil component of refined products such as jet fuel. However, just because rubber is a physical component of car tyres that does not mean that an entity can automatically designate rubber as a risk component in a hedge of forecast tyre purchases or sales, since the price of tyres could be related only indirectly to the price of rubber. Further analysis of the pricing structure of the whole car tyre would be required.

The determination of eligible non-contractually specified risk components is a judgemental area, so it is likely that some diversity in practice exists (see section 2.2.3 below).

It was reaffirmed by the IASB in developing IFRS 9 that it is not considered possible to determine that credit risk is an eligible risk component of a financial item. It was explained that the spread between the risk-free rate and the market rate of interest incorporates credit risk, liquidity, funding and other unidentified risk components and margin elements. Although it is possible to determine that the spread includes credit risk, the credit risk cannot be isolated in a way that would allow the change in fair value that is attributable solely to credit risk to be separately identifiable. A portion cannot just be a residual, i.e., an entity is not permitted to designate as a portion the residual fair value or cash flows of a hedged item or transaction if that residual does not have a separately measurable effect on the hedged item or transaction.

[IFRS 9.BC6.470, IFRS 9.BC6.517]. However, IFRS 9 does introduce an alternative accounting solution for entities undertaking economic credit risk hedging activity (see section 11.1 below).

2.2.2 Contractually specified risk components

Potential hedged items such as financial instruments, or purchase or sales agreements could contain clauses that link the contractual cash flows via a specified formula to a benchmark rate or price. The examples below all include a contractually specified risk component:

- The interest rate on a financial instrument contractually linked to a benchmark interest rate plus a fixed incremental spread
 - The coupon on a financial instrument contractually linked to an inflation or other financial index plus a determinable incremental spread
 - The price of natural gas contractually linked in part to a gas oil benchmark price and in part to a fuel oil benchmark price
 - The price of electricity contractually linked in part to a coal benchmark price and in part to transmission charges that include an inflation indexation
 - The price of wires contractually linked in part to a copper benchmark price and in part to a variable tolling charge reflecting energy costs
- And
- The price of coffee contractually linked in part to a benchmark price of Arabica coffee and in part to transportation charges that include a diesel price indexation

In each of the above examples, for items other than financial assets (for which embedded derivatives are never separated), it is assumed that the contractual pricing component would not require separation as an embedded derivative (see Chapter 42). The Illustration below provides a fuller example of the circumstances under which a contractually specified risk component might usefully be designated in a hedge relationship.

Illustration 2-1: Hedge of a contractually specified risk component - coal supply contract linked to the coal benchmark price and the Baltic Dry Index

An entity purchases coal from its coal supplier under a contract that sets out a variable price for coal linked to the coal benchmark price, represented by futures contracts for coal loaded at the Newcastle Coal Terminal in Australia, plus a logistics charge that is indexed to the Baltic Dry Index, reflecting that the delivery is at an overseas location. The contract sets out minimum purchase quantities for each month covered by its term. The entity wishes to hedge itself against price changes related to the benchmark coal price but does not want to hedge the price variability resulting from the logistics costs represented by the indexation of the coal contract to the Baltic Dry Index. Therefore, the entity enters into Newcastle coal futures contracts whereby it purchases coal for the relevant delivery months. For each relevant delivery month the entity designates the futures contracts as a hedging instrument in a cash flow hedge of the benchmark coal price risk component of the future coal purchases under its supply contract.

In this case the risk component is contractually specified by the pricing formula in the supply contract. This means it is separately identifiable, because the entity knows exactly which part of the change in the future purchase price of coal under its particular supply contract results from changes in the benchmark price for coal and what part of the price change results from changes in the Baltic Dry Index. The risk component can also be reliably measured using the price in the futures market for the relevant delivery months as inputs for calculating the present value of the cumulative change in the hedged cash flows. An entity could also decide to hedge only its exposure to variability in the coal price that is related to transportation costs. For example, the entity could enter into forward freight agreements and designate them as hedging instruments, with the hedged item being only the variability in the coal price under its supply contract that results from the indexation to the Baltic Dry Index.

When contractually specified, a risk component would usually be considered separately identifiable. [IFRS 9.BC6.174]. Further, the risk component element of an index/price formula would usually be referenced to observable data, such as a published index/price index. Therefore, the risk component would most likely also be considered reliably measurable.

Nevertheless, difficulties can still arise where a contractual negative spread exists in the hedged item, as a risk component must be less than the entire item. [IFRS 9.B6.3.7]. A negative spread arises when the formula for the contractual coupon/price includes a spread that is subtracted from the hedged risk component, so that the full contractual coupon/price is lower than the identified risk component. This has become termed the 'sub-benchmark rate issue' (discussed in section 2.4 below).

2.2.3 Non-contractually specified risk components

Not all contracts define the various pricing elements and, therefore, specify risk components. In fact, we expect most risk components of financial and non-financial items not to be contractually specified. While it is certainly easier to determine that a risk component is separately identifiable and reliably measurable if it is specified in the contract, IFRS 9 is clear that there is no need for a component to be contractually specified in order to be eligible for hedge accounting. The assessment of whether a risk component qualifies for hedge accounting (i.e., whether it is separately identifiable and reliably measurable) has to be made 'within the context of the particular market structure to which the risk or risks relate and in which the hedging activity takes place'. [IFRS 9.B6.3.9]. We understand 'market structure' here to mean the basis upon which market prices are established or the market conventions that are in evidence. Prices are typically established through a number of 'building blocks'. So, for instance, a benchmark interest rate such as SONIA might currently form the first building block in the valuation of a debt instrument (see section 2.2.3.A below), while a benchmark price, such as the LME price for copper, might form the first building block for the pricing of a non-financial item (see section 2.2.3.B below). The 'sub-benchmark' rate issue, (see section 2.4 below) will arise from negative spread building blocks, if as a result the identified non-contractually specified risk component is larger than the full contract itself.

2.2.3.A Non-contractual risk components in financial instruments

It has been common practice to identify a non-contractually specified risk-free interest rate or other benchmark interest rate component of the total interest rate exposure of a fixed rate or zero coupon hedged financial instrument. This approach is supported by an example provided within the application guidance of IFRS 9, presented as Illustration 2-2 below. IAS 39 also provides support for this approach as follows: "for a fixed rate financial instrument hedged for changes in fair value attributable to changes in a risk-free or benchmark rate, the risk-free or benchmark rate is normally regarded as both a separately identifiable component of the financial instrument and reliably measurable". [IAS 39.AG99F(a)].

Illustration 2-2: Identification of a benchmark interest rate component in fixed rate debt

Entity A has issued five-year debt with a fixed coupon of 5%. The debt is issued in an environment with a market in which a large variety of similar debt instruments are compared by their spreads to a benchmark rate (for example SONIA) and variable rate instruments in that environment are typically indexed to that benchmark rate. Interest rate swaps are frequently used to manage interest rate risk on the basis of the benchmark rate, irrespective of the spread on the debt instruments to that benchmark rate. The price of fixed rate debt instruments vary directly in response to changes in that benchmark rate as they happen. Accordingly, Entity A concludes that the benchmark rate is a separately identifiable and reliably measurable risk component of the fixed rate debt. [\[IFRS 9.B6.3.10\(d\)\]](#).

When the debt was issued, the prevailing five-year benchmark rate was 2%. In pricing the debt, Entity A included an additional spread of 3% above the benchmark rate to reflect credit risk and other factors. Entity A then transacted an interest rate swap at the prevailing five-year benchmark rate (i.e., pay floating benchmark rate, receive 2%). Entity A is able to designate the benchmark interest rate component of the issued debt (i.e., a five-year debt paying a 2% coupon) as the hedged item in a fair value hedge for changes in the benchmark interest rate with the interest rate swap as the hedging instrument.

Whilst in the past LIBOR has often been identified as an eligible risk component of a fixed rate or zero coupon hedged financial instrument, as part of global Interest Rate Benchmark Reform markets have moved away from LIBOR as the predominant benchmark interest rate, replacing it with various Risk Free Rates (RFRs). Accordingly, where LIBOR still exists as a designated risk in a hedge relationship, an assessment will be required as to whether LIBOR continues to meet the separately identifiable criteria within the relevant market structure. The IASB have addressed this and other accounting issues arising from Interest Rate Benchmark Reform, issuing two amendments to IFRS 9, and other impacted standards (see the *Supplement: IBOR Reform* for further discussion).

The example below provides another example of a non-contractually specified risk component of a financial instrument. It also illustrates how the market structure might be used to support the eligibility of the benchmark rate as a risk component for the particular hedged item.

Illustration 2-3: Identification of a benchmark interest rate component in government bonds

Entity XYZ holds Country A government bonds and has chosen to hedge the associated interest rate risk with Country B government bonds futures. Country A and B are part of a group of countries that have integrated economic and political policies, hence it is generally understood that Country A and Country B are strongly linked economically. Furthermore, Country B government bonds are considered to represent a risk free return in the region. Pricing for Country A government bonds is generally performed in relation to Country B government bonds, with an additional spread added to reflect Country A's sovereign credit risk.

Based on the market structure presented above, one might conclude that for Country A government bonds, Country B bond yields represent an eligible risk component as it is a separately identifiable risk component that can be reliably measured.

Although only debt instruments are mentioned in the two Illustrations above, the guidance is also applicable to other financial instruments such as lease receivables or insurance contracts (see section 2.2.7 for discussion on identifying an eligible risk component within insurance contracts).

This section discusses only the possibility of identifying a non-contractual benchmark interest rate as an eligible risk component in a financial instrument. There is no discussion on the possibility of identifying an eligible credit risk component as such a risk component is precluded by IFRS 9 (see section 2.2.1 above).

2.2.3.B Non-contractual risk components in non-financial instruments

An entity might be able to identify a non-contractual component in a non-financial item if within the particular market structure for that item, price negotiations ordinarily reflect a benchmark price plus other charges, similar to the contractual examples listed in section 2.2.2 above, even if this formula is not explicitly stated in the contract. The existence of contractually specified risk components in similar transactions can be a relevant factor in the assessment of the market structure and so help identify risk components when they are not contractually specified.

It could also be possible to identify non-contractually specified risk components in highly probable forecast items that are the subject of a cash flow hedge. Once such forecast items become contractual commitments it is possible that the risk components will be specified in the contract. In this case, if the entity has a past practice of entering into similar contracts, it could be relatively straightforward to demonstrate that a risk component can be identified in the forecast transactions within the context of the market structure.

The following Illustration based on an example from the application guidance of IFRS 9 shows the 'separately identifiable and reliably measurable' assessment.

Illustration 2-4: Hedge of a non-contractually specified risk component - coffee purchases with a benchmark price risk component

An entity purchases a particular quality of coffee of a particular origin from its supplier for the current harvest under a contract that sets out a variable price linked to the benchmark price for coffee. The price is represented by the coffee futures price plus a fixed spread, reflecting the different quality of the coffee purchased compared to the benchmark plus a variable logistics services charge reflecting that the delivery is at a specific manufacturing site of the entity. The fixed spread is set for the current harvest period only. For any deliveries that fall into the next harvest period this type of supply contract is not yet available.

The entity might wish to lock in the benchmark coffee price for future harvests, even though it does not yet have a supply contract. For such hedges of future coffee harvests, the entity analyses the market structure for its coffee supplies, taking into account how the eventual deliveries of coffee that it receives are priced. The entity has an expectation that it will enter into similar supply contracts for each future harvest period once the crop relevant for its particular purchases is known and the spread can be set. In that sense, the knowledge about the pricing under existing supply contracts also informs the entity's analysis of the market structure more widely, including forecast purchases which are not yet contractually specified. This allows the entity to conclude that its exposure to variability of cash flows resulting from changes in the benchmark coffee price is a risk component that is separately identifiable and reliably measurable for forecast coffee purchases that fall into the next harvest period (i.e., prior to the existence of a supply contract), as well as those for the current harvest period which are under a supply contract. [IFRS 9.B6.3.10(b)].

In this case the entity can enter into coffee futures contracts to hedge its exposure to the variability in cash flows from the benchmark coffee price and designate that risk component as the hedged item for harvests for which the pricing is not yet subject to a supply contract. This means that changes in the contractual price due to the variable logistics services charge and future changes in the spread reflecting the quality of the coffee, would be excluded from the hedging relationship.

The assessment of whether a risk component qualifies for hedge accounting is mainly driven by an analysis of whether there are different pricing factors that have a distinguishable effect on the item as a whole (in terms of its fair value or its cash flows). This evaluation would always have to be based on relevant facts and circumstances. While it is probably not necessary that each component of the price of the non-financial item is observable in the market (for instance, transport costs could be specific to a particular transaction), it will be necessary to demonstrate that components that are designated as hedged items do have a distinguishable effect and are not 'drowned out' by the variability of other, unobservable components. For example, it is relatively common for the calculation of fair value of an equity instrument for which there are no observable inputs to include discounting of future cash flows at a market rate of interest. However, it is difficult to conclude that changes in that market rate of interest would have a distinguishable effect on the fair value of the equity instrument. Hence it is very unlikely that interest rate risk would meet the criteria to be an eligible risk component for equity instruments.

The standard uses the refinement of crude oil to jet fuel as an example to demonstrate how the assessment of the market structure could be made to conclude that crude oil in a particular situation is an eligible risk component of jet fuel. [IFRS 9.B6.3.10(c)]. Crude oil is a physical input of the most common production process for jet fuel and there is a well-established price relationship between the two. The components of jet fuel will include the price of crude oil and the various 'crack spreads' relating to the refining process, plus possibly transport costs. While there might be no market to measure reliably the crack spreads beyond a certain time horizon, if it can be shown that the market does regard the crude oil price as a building block, and it has a distinguishable effect on the price of jet fuel, then the crude oil component could be designated as the hedged item for longer time periods. Similarly, it could be possible to designate the crack spread, if it can be traded or is otherwise sufficiently observable that it could be regarded as reliably measurable.

Therefore, in order to conclude that benchmark price components are eligible risk components of an item, there is an expectation that any residual building block component would either be relatively stable or else any fluctuations can be explained rationally within the particular market structure (e.g., quality differences or transportation costs). Accordingly, just because the full price of an item approximates to, or is highly correlated with, a particular benchmark price, that will be insufficient on its own to demonstrate that the benchmark price can be identified as a component within the context of the particular market structure.

Extending the example of crude oil, it is also a major input in the production process for plastic. However, the manufacturing process is complex and involves a number of steps. The process starts with crude oil being distilled into its separate 'fractions', of which only one (naphtha) is used for making plastic. Naphtha then undergoes a number of further processes before the various types of plastic are finally produced.

Consequently, any impact of a change in the price of crude oil on the price of plastic is likely to be significantly diluted by the costs of manufacturing and the passage of time.

Generally, the further 'downstream' in the production process an item is, the more difficult it is to find a distinguishable effect of any single pricing factor. The mere fact that a commodity is a major physical input in a production process does not automatically translate into a separately identifiable effect on the price of the item as a whole. For example, the price for pasta at food retailers in the medium to long term also responds to changes in the price for wheat, but there is no distinguishable direct effect from changes in wheat prices on the retail price for pasta, which remains unchanged for longer periods even though wheat prices are likely to change more frequently. If retail prices are only periodically adjusted in a way that directionally reflects the effect of wheat price changes, that is not sufficient to constitute a separately identifiable risk component.

Determining whether non-contractually specified risk components are eligible as hedged items requires judgement. The economic analysis ordinarily undertaken by an entity prior to undertaking risk management activity will most likely form the basis in making this judgement. However, care needs to be taken to ensure the existing economic analysis sufficiently meets the requirements of the standard, that a risk component is separately identifiable and reliably measurable within the relevant market structure. [IFRS 9.B6.3.8, IFRS 9.B6.3.9]. Given the judgements involved, diversity in practice could exist as to what are commonly accepted non-contractual risk components and the approach taken to determine their existence, depending on the particular facts and circumstances.

2.2.4 Partial term hedging

A common risk management technique is to hedge a risk for only a partial term for which it is outstanding, as illustrated in Illustration 2-5 below. The example, which is based on the Implementation Guidance of IAS 39, illustrates that a time portion of interest rate risk can be a separately identifiable and reliably measurable risk component of a financial instrument, and remains relevant under IFRS 9. Accordingly, it is possible to designate a financial instrument as a hedged item for the portion of risk that represents only part of the term that a hedged item remains outstanding. However, it is not possible to designate a partial term of a hedging instrument. [IFRS 9.6.2.4].

Illustration 2-5: Partial term hedging

Company A acquires a 10% fixed-rate government bond with a remaining term to maturity of ten years and classifies it as at amortised cost. To hedge against the fair value exposure on the bond associated with the first five years' interest payments, it acquires a five year pay-fixed receive-floating swap.

The swap may be designated as hedging the fair value exposure of the interest rate payments on the government bond until year five and the change in value of the principal payment due at maturity to the extent affected by changes in the yield curve relating to the five years of the swap. [IAS 39.F.2.17].

As the hedged risk is restricted to a partial term, then for effectiveness purposes only changes in the part of the yield curve related to that partial term are relevant in calculating the gain or loss on the hedged item. [IFRS 9.B6.3.11]. For effectiveness purposes the part of the yield curve relating to longer maturities is assumed to remain the same. Hence in this fact pattern, six months after initial designation, ineffectiveness would be measured by comparing the difference between the change in value of the hedged cash flows with respect to changes in the yield curve relating to the next four and a half years and the change in the full fair value of the interest rate swap.

Whilst the above Implementation Guidance uses the example of a financial instrument, the same conclusion could be reached for hedging a partial term of a non-financial instrument. For example, an entity might wish to hedge the foreign currency risk for the next three months from a highly probable forecast purchase cash flow in six months' time. The six month forward foreign currency rate is driven by the relationship between spot rates and forward rates for any given yield curve. Furthermore, the market is built on the premise that a six-month forward rate is a combination of the three-month forward rate (i.e., the market rate for months one to three), and the three-month forward forward rate (i.e., the market rate for months four to six). This market structure would appear to support being able to hedge a partial risk component of a highly probable forecast purchase cash flow.

Consistent with other documented risk components, if a partial term hedge is designated, the qualifying criteria apply, including that the hedging relationship must meet the hedge effectiveness requirements, and any hedge ineffectiveness must be measured and recognised, albeit only with respect to the hedged risk (i.e., the designated partial term), and not the full item (see section 2.1 above and sections 6 and 7.4 below). [IFRS 9.B6.3.11, IFRS 9.B6.4.1].

An alternative risk management strategy would be a rollover strategy, i.e., when the maturity of the hedging instrument is intentionally shorter than the maturity of the hedged item, and there is an expectation that on expiry of the original hedging instrument it will be replaced by a new hedging instrument (see section 7.7 below). Applying a rollover strategy is not the same as identifying a risk component and so it is not the same as a partial term hedge.

2.2.5 Foreign currency as a risk component

One risk component that is frequently designated as an eligible risk component is foreign currency risk. [IFRS 9.BC6.176]. It is relatively easy to determine that foreign currency risk is a separately identifiable component of a financial instrument denominated in a foreign currency, and that the changes in the cash flows or fair value of the instrument attributable to changes in foreign currency risk are reliably measurable at least for most frequently traded currency pairs.

Similarly, for highly probable forecast foreign currency cash flows in a cash flow hedge, it could be relatively easy to conclude that variation in foreign currency rates does have a distinguishable effect on the hedged cash flows, unless the foreign currency is just a 'settlement currency' (see below). (See section 5.2 below for more discussion on cash flow hedges). Illustration 2-6 below provides an example of a cash flow hedge of highly probable forecast foreign currency cash flows.

It is less straight forward, however, to reach a similar conclusion for non-financial items purchased or sold in a foreign currency that are designated in a fair value hedge (see section 5.1 below for more discussion on fair value hedges). In June 2019,¹ the IFRS IC discussed whether foreign currency risk can be a separately identifiable and reliably measurable risk component of a non-financial asset held for consumption that an entity can designate as the hedged item in a fair value hedge accounting relationship. The IFRS IC confirmed their agenda decision on this topic at the September 2019 meeting.

As part of the discussion, the IFRS IC considered whether an entity could have exposure to foreign currency risk on a non-financial asset that is a separately identifiable and reliably measurable risk component. The IFRS IC concluded that this can be the case, depending on an assessment of the particular facts and circumstances within the context of the particular market structure. The IFRS IC further concluded that this would be the case if at a global level, changes in fair value of the non-financial asset are determined only in one particular currency and that currency is not the entity's functional currency. If the fair value of a non-financial asset is determined in a foreign currency, applying IAS 21 the measure of fair value that could affect profit or loss is the fair value translated into an entity's functional currency (translated fair value). The translated fair value of such a non-financial asset would change as a result of changes in the applicable exchange rate in a given period, even if the fair value (determined in the foreign currency) were to remain constant. For example, as purchases and sales of wide-bodied aircraft are routinely globally determined in US dollars, it might be possible for an entity with a functional currency other than US dollars to identify an eligible foreign currency risk component in a wide-bodied aircraft that it owns (see section 2.6.8 below).

As noted above, the IFRS IC discussion as to whether foreign currency risk is a separately identifiable and reliably measurable risk component of a non-financial asset held for consumption was part of a wider debate on the eligibility of designating such a risk component in a valid hedge relationship. In order to achieve hedge accounting for such a risk component, consideration must also be given to all the qualifying criteria for hedge accounting (see section 6 below) and in particular those discussed by the IFRS IC in June 2019. These include the requirement that the changes in fair value could affect profit or loss and that the relationship is consistent with the entity's actual risk management (see sections 2.6.8, 5.1 and 6.2.1 below). Illustration 2-7 below provides an example of a fair value hedge of inventory for which the price is determined globally in a foreign currency.

Prior to designation of foreign currency risk in a non-financial instrument in a fair value hedge, careful analysis and judgement will likely be required to determine that foreign currency risk is a separately identifiable component of a non-financial instrument for which the changes in the cash flows or fair value of the non-financial asset attributable to changes in that foreign currency risk are reliably measurable.

¹ [IFRIC Update](#), June 2019, available on the IFRS Foundation's website.

The IFRS IC also noted that the fact that market transactions are commonly settled in a particular currency does not necessarily mean that this is the currency in which the non-financial asset is priced and thus the currency in which its fair value is determined. The currency could be purely a 'settlement currency'. A 'settlement currency' might arise where the price is determined in one foreign currency but settled in another (i.e., the settlement currency) at the prevailing foreign currency rate on settlement. In that instance it is difficult to argue that changes in the foreign currency risk between an entity's functional currency and the settlement currency have a reliably measurable impact on the cash flows or fair value of the hedged item. In fact, it is the foreign currency risk between an entity's functional currency and the currency that drives the pricing of the hedged item that is more likely to be an eligible risk component.

Although the IFRS IC discussion was limited to foreign currency risk in a non-financial instrument in a fair value hedge, the guidance on a settlement currency is also relevant for highly probable forecast foreign currency cash flows.

Accordingly, consideration is required to determine that any 'foreign currency risk' is an eligible risk component in a non-financial instrument or highly probable forecast foreign currency cash flow, and is not merely due to the use of a settlement currency.

Furthermore, although it is not explicit in the standard, it seems reasonable that an entity could identify a risk component of an exposure for risk(s) excluding foreign currency risk. The designation of a foreign currency risk component, and a risk component excluding foreign currency risk for a cash flow hedge and a fair value hedge are both shown in the following Illustrations.

Illustration 2-6: Cash flow hedge of foreign currency denominated commodity risk

Company P has the Rand as its functional currency. It has forecast, with a high probability, the need to purchase a 1,000 barrels quantity of crude oil for US Dollars in twelve months' time. The price of crude oil is routinely denominated in US Dollars globally and so is the currency in which the price of crude oil is determined, hence it is clear that US Dollars are not purely a settlement currency. In that case it appears that both the US Dollar price of crude oil and the Rand to US Dollar exchange rate are each eligible risk components of the forecast purchase of crude oil by Company P.

Scenario 1: designation of a risk component excluding foreign currency risk

To hedge part of its exposure to the price risk inherent in this purchase, P enters into an exchange traded twelve-month cash-settled crude oil forward contract. The price at which the forward is determined is denominated in US dollars (there is no active market in Rand denominated crude oil futures) and P therefore fixes the US dollar price of the 1,000 barrels of oil to be purchased. As part of its risk management assessment P chooses not to hedge the risk associated with Rand to US dollar exchange rates. This might be because of illiquidity in the foreign currency markets for Rand or, perhaps, because P has forecast US dollar inflows that provide a natural hedge of the foreign currency risk.

P could designate the US Dollar crude oil forward contract as the hedging instrument in a cash flow hedge of changes in the US Dollar crude oil price in the highly probable forecast purchase of crude oil (see also Illustration 7.4 in section 7.2.1 below).

Scenario 2: designation of foreign currency as a risk component

To hedge part of the risk associated with Rand to US dollar exchange rates, P could transact a forward foreign currency contract to buy US dollar and sell Rand in twelve months' time. As part of its risk management assessment P chooses not to hedge the US Dollar crude oil price risk associated with the forecast purchase of crude oil. The foreign currency forward contract can be designated as the hedging instrument in a hedge of the foreign currency risk exposure to the US dollar denominated price risk associated with its forecast purchase of crude oil.

The forward foreign currency contract would hedge an amount of US dollars, e.g., USD10,000, so Company P would also need to ensure that it was highly probable that a cash flow of at least USD10,000 will arise from forecast purchases of oil. As P has chosen not to hedge changes in the US Dollar crude oil price, there is a risk that the amount of US Dollars paid on the purchase of the crude oil will be below USD10,000 if the US Dollar price of crude oil has fallen. The likelihood of this scenario will need to be factored into the highly probable assessment and could ultimately restrict the amount of US Dollar cash flows eligible to be designated within the hedge relationship (see section 2.6.1 below).

It is possible that subsequently P may choose to hedge the foreign currency risk in Scenario 1, or the crude oil price risk in Scenario 2 in addition to the existing risk management. The application of hedge accounting for this subsequent risk management activity is likely to require designation of an aggregated exposure which can be complex (see section 2.7.2 below).

Illustration 2-7: Fair value hedge of foreign currency denominated commodity risk

Company X has the euro as its functional currency. It has 1,000 tonnes of Commodity 1 inventory carried at cost as per IAS 2 *Inventories* (see Chapter 23). Commodity 1 is routinely denominated in US Dollars globally. Commodity 1 and certain associated derivatives are readily traded in active markets at a US Dollar price.

Scenario 1: designation of a risk component excluding foreign currency risk

As part of its risk management activities Company X wishes to protect the value of its commodity inventory against falls in the US Dollar price of Commodity 1 over a three-month period.

To hedge the fair value risk of the inventory Company X transacts an exchange traded three-month cash-settled commodity forward contract to sell 1,000 tonnes of Commodity 1. The price at which the forward is determined is denominated in US Dollars. X is now protected against changes in the US Dollar fair value of the Commodity 1 inventory for the next three months.

X wishes to designate the commodity forward contract as the hedging instrument in a fair value hedge of the 1,000 tonnes of Commodity 1 inventory.

Although the inventory is carried at cost, fair value changes in the inventory could affect profit or loss when it is sold or written down (see section 5.1 below). [IAS 39.F.3.6].

The fair value of Commodity 1 is based solely on the quoted US dollar price for Commodity 1 globally, and euro/US Dollar foreign currency risk is widely traded. Hence both the US Dollar price and the associated euro/US Dollar foreign currency risk are separately identifiable and reliably measurable risk components of X's Commodity 1 inventory.

X has transacted the commodity forward contract in line with its risk management activities.

In that case X can designate the Commodity 1 forward contract as the hedging instrument in a fair value hedge of changes in the US Dollar fair value of the 1,000 tonnes of Commodity 1 inventory.

Scenario 2: designation of foreign currency as a risk component

To hedge part of the risk associated with euro/US Dollar foreign currency rates arising from the 1,000 tonnes of Commodity 1 inventory, X transacts a forward foreign currency contract to sell US Dollar and buy euros in three months' time. As part of its risk management assessment X chooses not to hedge the US Dollar Commodity 1 price risk associated with the inventory.

Applying the same logic as in Scenario 1 above, euro/US Dollar foreign currency risk is an eligible risk component of the 1,000 tonnes of Commodity 1 inventory and the inventory could be designated as the hedged item within a fair value hedge with the forward foreign currency contract as the hedging instrument.

As the fair value of the Commodity 1 inventory varies due to both the US Dollar commodity price and the associated euro/US Dollar foreign currency risk the forward foreign currency contract would need to be designated as hedging a nominal bottom layer component defined by an amount of US dollars, e.g., USD2,000 (see section 2.3.1 below). There is an additional consideration when hedging the bottom layer in a fair value hedge that tracking of the hedged item to which the fair value hedge adjustment relates is required (see section 2.3.1 below). [IFRS 9.B6.3.19]. Since the amount of US dollars is driven by the price of the commodity, a decrease in the price of the commodity could lead to ineffectiveness if the bottom layer is breached.

2.2.6 Inflation as a risk component

A contractually specified inflation risk component of the cash flows of a recognised inflation-linked bond liability (assuming that there is no requirement to account for an embedded derivative separately - see Chapter 42) is separately identifiable and reliably measurable, as long as other cash flows of the instrument are not affected by the inflation risk component. [IFRS 9.B6.3.15].

However, IFRS 9 includes a rebuttable presumption that for financial instruments, unless contractually specified, inflation is not separately identifiable and reliably measurable. This means that there are limited cases under which it is possible to identify inflation as a non-contractually specified risk component of a financial instrument and designate that inflation component in a hedging relationship. Similar to other non-contractually specified risk components (see section 2.2.3 above), the analysis would have to be based on the particular circumstances in the respective market, which is, in this case, the debt market. [IFRS 9.B6.3.9, IFRS 9.B6.3.13].

The notion of inflation being a separately identifiable component of a financial instrument is based on economic theory, specifically the Fisher equation, that the real interest rate equals the nominal interest rate minus the expected inflation rate. The equation is more accurately expressed as follows:

$$(1 + i) = (1 + r) \times (1 + \pi)$$

Where:

i = The nominal interest rate (i.e., the actual interest rate paid)

r = The real interest rate (i.e., the rate of interest after allowing for inflation)

π = The inflation rate

In a sufficiently liquid debt market, it will be possible to demonstrate the existence of the Fisher equation in practice and rebut the presumption that, unless contractually specified, inflation is not separately identifiable and reliably measurable in a financial instrument. The example below, derived from the application guidance of IFRS 9, explains a situation in which the presumption that inflation does not qualify as a risk component of a financial instrument can be rebutted.

Illustration 2-8: Inflation risk as an eligible risk component of a debt instrument

An entity wishes to hedge the inflation risk component of a debt instrument. The debt instrument is issued in a currency and country in which inflation-linked bonds are actively traded in a significant volume. The volume, liquidity and term structure of these inflation-linked bonds allow the computation of a real interest yield curve. This means that for the respective currency, inflation is a relevant factor that is separately considered by the debt markets. This situation supports that inflation is a factor that is separately considered in the debt market in a way that it is a separately identifiable and reliably measurable risk component. [IFRS 9.B6.3.14].

In December 2020, the IFRS IC first considered whether a hedge of the variability in cash flows arising from changes in real rates, rather than nominal interest rates could be accounted for as a cash flow hedge. More specifically, the fact pattern considered was a hedge of a floating rate (LIBOR) debt with an inflation swap (which swaps the variable interest cash flows of the floating rate debt for variable cash flows based on an inflation index). The IFRS IC considered whether the entity can designate the swap in a cash flow hedge relationship as a hedge of the variable interest payments for changes in the real interest rate component. The IFRS IC confirmed its agenda decision in April 2021.²

Two key questions arose, both of which are discussed in more detail below:

- Whether that risk component is separately identifiable and reliably measurable as required by IFRS 9.6.3.7(a)
- And
- As a result, whether the entity has exposure to variability in cash flows that is attributable to the real interest rate risk component of the floating rate instrument as required by IFRS 9.6.5.2(b)

The IFRS IC noted that when assessing whether real interest rates are separately identifiable and reliably measurable for floating rate instruments, the relevant market structure is the one in which the floating rate instruments are issued and in which hedging activity will take place. For the market structure to support the eligibility of that risk component in the proposed cash flow hedge relationship, the real interest rate must represent an identifiable pricing element in setting the floating benchmark interest rate, thereby creating separately identifiable and reliably measurable cash flow variability in the floating rate instrument.

The IFRS IC concluded that, because nominal rates generally do not change as a direct result of changes in real interest rates, the existence of a term structure of zero-coupon real interest rates (see Illustration 2-8 above) is not, in itself, sufficient to overcome the rebuttable presumption that inflation (and by association real rates) are separately identifiable and reliably measurable in floating rate debt instruments.

[IFRS 9.B6.3.13].

The IFRS IC further noted that cash flows are, by their nature, denominated in nominal terms and that the interest rate for floating rate financial instruments is defined in nominal terms for a given currency. Therefore, the assessment of whether there is any variability in cash flows from floating rate debt due to changes in real rates must also be undertaken on a nominal basis. A nominal interest rate (such as LIBOR) could be influenced by expected inflation and the real interest rate in the long term. However, nominal interest rates do not change as a direct result of changes in inflation or the real interest rate (that is, they are not identifiable pricing elements in setting nominal rates).

² [IFRIC Update](#), April 2021, available on the IFRS Foundation's website.

The IFRS IC therefore concluded that there is no exposure to variability in cash flows that is attributable to changes in the real interest rate in the proposed cash flow hedge relationship and, thus cash flow hedge accounting would be precluded. [IFRS 9.6.5.2(b)].

Consequently, the proposed real interest rate risk component in a hedge of floating rate debt is not an eligible hedged item in cash flow hedge relationship.

Based on this analysis, it is also clear that, although the rebuttable presumption in IFRS 9.B6.3.13 applies to both fair value hedges and cash flow hedges, the example in Illustration 2-8 above illustrates a rebuttal of the presumption in a fair value hedge only.

However, even when considering a rebuttal of the presumption for a fair value hedge there are not many currencies with a liquid market for inflation-linked debt instruments, therefore further limiting the availability of designating non-contractually specified inflation risk components of financial instruments. In addition, even where the presumption is successfully rebutted, the other qualifying criteria must be met in order to apply hedge accounting (see section 6 below). In particular, demonstrating the existence of an economic relationship such that the hedged item and the hedging instrument have values that are generally expected to move in opposite directions could prove challenging, given all the fair value drivers for an inflation derivative. [IFRS 9.B6.4.4].

How we see it

Following the April 2021 final agenda decision of the IFRS IC (see above), and in consideration of the existing rebuttable presumption that inflation is not separately identifiable in a financial instrument unless contractual, coupled with the difficulties of meeting the hedge effectiveness requirements in a fair value hedge of inflation risk (in particular the existence of an economic relationship), it is difficult to identify a fact pattern for which hedge accounting for non-contractual inflation risk in a financial instrument might be achieved.

While IFRS 9 defines in what circumstances inflation can be a risk component for a financial instrument, inflation can be treated as a risk component for non-financial items under IFRS 9 in the same manner as any other risk component (as described in sections 2.2.2 and 2.2.3 above), i.e., the rebuttable presumption described in this section applies only to financial instruments.

2.2.7 Interest rate risk component in an insurance contract

Entities that write longer term insurance contracts (typically life products paying annuities) often use derivatives to manage the interest rate risk they associate with those insurance liabilities. On application of IFRS 17 *Insurance Contracts* (see Chapter 51) insurance entities may be inclined to apply hedge accounting to their interest rate risk management derivatives in order to avoid an accounting mismatch and better represent risk management in their financial statements.

IFRS 9 is silent on the application of hedge accounting to insurance contracts, hence the standard IFRS 9 hedge accounting criteria must be applied, in particular, the guidance on eligible hedged components. In order for a risk component to be eligible, the risk component must be separately identifiable and reliably measurable. This assessment must be made within the context of a particular market structure (see section 2.2.3.A above). [IFRS 9.B6.3.8, IFRS 9.B6.3.9].

IFRS 9 provides guidance on how to determine whether a benchmark interest rate is separately identifiable and reliably measurable component of fixed rate debt within the market structure (see section 2.2.3.A above). [IFRS 9.B6.3.10(d)]. This guidance is also relevant in consideration of insurance contracts, however the bespoke and complex features often seen in insurance contracts make the guidance more difficult to interpret in the context of insurance contracts.

Given the wide variety of insurance contracts, and their complex nature arising from various interrelated risk drivers, the assessment of whether a benchmark interest rate risk is eligible as a hedged component of an insurance contract in a fair value hedge will need to be undertaken for the particular facts and circumstances. Consideration as to what is the 'particular market structure' will also be important. Often there is a lack of a clear primary and, possibly, even a secondary market for insurance contracts (i.e., evidence suggests that in many markets, very few sales of insurance contracts occur post origination). Therefore, in some circumstances, it has been suggested that it could be appropriate to interpret 'market structure' as meaning the basis upon which market origination prices are established or the market conventions for fair value determination if such common market practices exist, perhaps driven by regulation. If an eligible benchmark interest rate component exists, there is an expectation it can be demonstrated, within the market structure, that changes in benchmark interest rates do have a determinable impact on the pricing and/or fair values of the particular insurance contracts. This is an area where practice could evolve in the future.

When it has been determined that a benchmark interest rate component does exist within a group of insurance contracts, consideration must be given as to how lapse risk is incorporated into a hedge relationship (lapse risk is the risk that the actual behaviour of policy holders with respect to termination or breaking of insurance contracts is different to the assumptions used in pricing and managing those contracts). Like the identification of an eligible risk component, there will need to be an assessment of the relationship between lapse risk and benchmark interest rate risk within insurance contracts, taking into account the particular facts and circumstances to determine whether lapse risk is driven by changes in benchmark interest rate risk or not. If it is determined that lapse risk is driven by changes in benchmark interest rate risk, it must form part of the fair value adjustment. All the features of the hedged item whose fair value is affected by changes in the hedged risk must be included in the hedge relationship, otherwise the measurement of hedge effectiveness would not include the full fair value change with respect to the hedged risk. [IFRS 9.BC6.204].

Whether or not changes in lapse risk must be incorporated in the remeasurement of the hedged component within a fair value hedge relationship could have a significant impact on the levels of ineffectiveness (see section 7.1.1 below). Lapse risk within a portfolio of insurance contracts is comparable to pre-payment risk in a portfolio of fixed rate prepayable mortgages for interest rate risk management purposes. Despite the fact insurance contracts are outside the scope of IFRS 9, they are typically financial instruments so it makes some sense to apply a parallel treatment to lapse risk in a portfolio of insurance contracts to the treatment of prepayment risk in prepayable fixed rate mortgages within the portfolio fair value hedging guidance in IAS 39 (see section 10 below). In that case if it can be demonstrated that lapse risk is not driven by changes in benchmark interest rate, then changes in lapse risk would not form part of the gain or loss on the hedged risk. [IAS 39.AG121].

If it is determined that lapse risk is not driven by changes in benchmark interest rate risk and so will not form part of the fair value hedge adjustment, changes in lapse risk could still result in a designated hedged item no longer existing. Therefore, there will be a need to track any hedge designations to ensure fair value hedge adjustments are accounted for appropriately, and in particular are released to profit or loss if the hedged item no longer exists (see sections 7.1.2 and 8.3.1 below).

2.3 Components of a nominal amount

2.3.1 General requirement

A component of a nominal amount is a specified part of the amount of an item. [IFRS 9.6.3.7(c)]. This could be a proportion of an entire item (such as, 60% of a fixed rate loan of EUR100 million) or a layer component (for example, the 'bottom layer' of EUR60 million of a EUR100 million fixed rate loan that can be prepaid at fair value. 'Bottom layer' here refers to the portion of the loan that will be prepaid last). The type of component changes the accounting outcome. An entity must designate the component for accounting purposes consistently with its risk management objective (see section 6.2 below). [IFRS 9.B6.3.16, IFRS 9.B6.3.17].

A component must be less than the entire item, [IFRS 9.B6.3.7], and must be defined in such a way that it is possible to determine whether the usual effectiveness criteria are met and ongoing ineffectiveness can be measured. (See sections 6.4 and 7.4 respectively below).

In particular the need for documented specificity of the hedged item was reiterated by the IFRS IC in March 2019 in a discussion within the context of the Application of the Highly Probable Requirement when a Specific Derivative is Designated as a Hedging Instrument (IFRS 9 and IAS 39).³ The IFRS IC discussed the application of the highly probable requirement with respect to a specific derivative (a loan following swap) designated as a hedging instrument. In a loan following swap the notional amount of the derivative designated as a hedging instrument varies depending on the outcome of the hedged item (e.g., forecast energy sales). The IFRS IC observed that forecast sales cannot be specified solely as a percentage of sales during a period because that would lack the required specificity in terms of magnitude and timing (see section 2.6.1 and section 6.3.3 below). It follows that for all hedge designations a known amount or component of hedged item must be identified. This would preclude any designations for which the designated amount or component of the hedged item is contingent, for example on the performance of market rate or indices. It follows that if the notional amount of the hedging derivative varies (e.g., a foreign currency forward contract with notional of CU100m plus an embedded knock in option to increase the notional to CU150m if a particular foreign currency rate is reached) that variability cannot be replicated in the designation of the hedged item.

³ [IFRIC Update](#), March 2019, available on the IFRS Foundation's website

Even if the foreign currency forward contract with the embedded knock in option in the example was designated as hedging a known amount of hedged item it is unlikely to be an eligible hedge relationship. Consideration of the existence of an economic relationship and potentially whether the hedging instrument is a net written option could preclude hedge accounting (see sections 3.2.2, 3.6.2 and 6.4.1 below).

An increasingly common example of contracts for which the notional amount may not be known in advance is long term contracts for renewable energy, often referred to as power purchase agreements. These could be either physical power purchase agreements (PPAs) or virtual power purchase agreements (VPPAs). In addition to the issues identified above in cases where the notional amount of the power purchase agreements is not known, achieving hedge accounting for these contracts can be very complex (see section 3.2.6 below). In 2023 specific questions relating to power purchase agreements were submitted to the IFRS IC and escalated to the IASB. The IASB added a maintenance project to the work plan to explore whether narrow-scope amendments could be made to IFRS 9 to better reflect how financial statements are affected by purchase power agreements. On 18 December 2024, the IASB published Amendments to IFRS 9 and IFRS 7 - Contracts Referencing Nature-dependent Electricity.⁴ The narrow scope amendments relate solely to contracts referencing nature-dependent electricity, which may not include all PPA or VPPA contracts. The amendments address how the 'own-use' requirements apply to in-scope contracts, amend the designation requirements for a hedged item in a cash flow hedging relationship for in-scope contracts, and add new disclosure requirements (see section 3.2.6.A below).⁵

Nominal layer components are frequently used in risk management activities in practice. For hedge accounting purposes it is possible to designate a layer in a defined, but open, population (see examples (a) and (c) below), or from a defined nominal amount (see examples (b) and (d) below). An open population is one where the items within the population are not restricted to items that already exist. IFRS 9 includes the following examples of layers that could be eligible for hedge designation: [IFRS 9.B6.3.18]

Extract from IFRS 9

B6.3.18 A layer component may be specified from a defined, but open, population, or from a defined nominal amount. Examples include:

- (a) part of a monetary transaction volume, for example, the next FC10 cash flows from sales denominated in a foreign currency after the first FC20 in March 201X;⁵
- (b) a part of a physical volume, for example, the bottom layer, measuring 5 million cubic metres, of the natural gas stored in location XYZ;
- (c) a part of a physical or other transaction volume, for example, the first 100 barrels of the oil purchases in June 201X or the first 100 MWh of electricity sales in June 201X; or
- (d) a layer from the nominal amount of the hedged item, for example, the last CU80 million of a CU100 million firm commitment, the bottom layer of CU20 million of a CU100 million fixed-rate bond or the top layer of CU30 million from a total amount of CU100 million of fixed rate debt that can be prepaid at fair value (the defined nominal amount is CU100 million).

⁵ In this Standard monetary amounts are denominated in 'currency units' (CU) and 'foreign currency units' (FC).

[IFRS 9.B6.3.18].

The ability to designate a 'bottom layer' nominal component for a group of forecast cash flows, such as the sale of the first 15,000 units of widgets, used in example (c) above, accommodates the fact that there could be a level of uncertainty as to the quantity of the hedged item. The bottom layer designation means that any uncertainty in forecast cash flows 'above' the bottom layer does not negatively impact the assessment as to whether the bottom layer itself is eligible as a hedged item (i.e., meets the highly probable requirement) (see section 2.6.1 below). However, it would not be possible to designate a 'top layer' nominal component for a group of forecast cash flows, as it is not possible to determine when that top layer occurs, as more forecast cash flows could always follow (see section 6.3.3 below). [IAS 39.F.3.10].

⁴ [IFRS - IASB updates IFRS Accounting Standards for nature-dependent electricity contracts](#)

⁵ [IFRS - Power Purchase Agreements](#) available on the IFRS Foundation's website.

There are additional requirements if a layer is designated within a fair value hedge. An entity must specify it as a portion of a nominal amount, e.g., the top CHF 20 million layer of a CHF 100 million fixed rate liability. Accounting for a fair value hedge requires remeasurement of the hedged item for fair value changes attributable to the hedged risk (see section 7.1.1 below). In addition, that fair value hedge adjustment must be recognised in profit or loss no later than when the hedged item is derecognised (see section 7.1.2 below). Accordingly, it is necessary to track the designated hedged item so it can be determined when the hedged item has been derecognised. Applying this requirement to the example of a top CHF 20 million layer of a CHF 100 million fixed rate liability, the total defined nominal amount of CHF 100 million fixed rate liability must be tracked in order to identify when the specified CHF 20 million top layer is derecognised. [IFRS 9.B6.3.19]. If it is not possible to define a nominal amount in a way that facilitates tracking of the hedged item to which the fair value hedge adjustment relates, then hedge accounting would be precluded. Further analysis is also required on the ability to designate layers within a fair value hedge where there is prepayment risk (see section 2.3.2 below).

2.3.2 Layer component for fair value hedges with prepayment risk

Although IFRS 9 allows the designation of layer components from a defined nominal amount as long as it is consistent with an entity's risk management objective (see section 2.3.1 above), there are some additional considerations for fair value hedges where prepayment risk exists. [IFRS 9.B6.3.18, IFRS 9.B6.3.19].

A layer component that includes a prepayment option does not qualify as a hedged item in a fair value hedge if the fair value of the prepayment option is affected by changes in the hedged risk, unless the changes in fair value of the prepayment option as a result of changes in the hedged risk are included when measuring the change in fair value of the hedged item (see Illustration 2-10 below). [IFRS 9.B6.3.20]. However, if the hedged item includes a prepayment option such that it is prepayable at fair value, the fair value of the option is not affected by changes in the hedged risk, and hence it would be possible to designate a layer component in a fair value hedge with little or no ineffectiveness due to changes in the fair value of the option when measuring the hedged item (see Illustration 2-9 below).

Illustration 2-9: Hedging a top layer of a loan prepayable at fair value

An entity borrows money by issuing a CU10m five-year fixed rate loan. The entity has a prepayment option to pay back CU5m at fair value. The entity wants to be able to make use of the prepayment option without the amount repayable on early redemption being affected by interest rate changes. Consequently, the entity would like to hedge the fair value interest rate risk of the prepayable part of the loan. The fair value of the prepayment option is not affected by changes in the hedged risk as the layer is prepayable at fair value, hence it is possible to designate the top layer in a fair value hedge of interest rate risk. To achieve this, the entity enters into a five-year receive fixed/pay variable interest rate swap (IRS) with a notional amount of CU5m. The entity designates the IRS in a fair value hedge of the interest rate risk of the CU5m top layer of the loan attributable to the benchmark interest rate. As a result, the top layer is adjusted for changes in the fair value that are attributable to changes in the hedged risk. The bottom layer, which cannot be prepaid and is not hedged, remains at amortised cost.

The gain or loss on the IRS will offset the change in fair value on the top layer attributable to the hedged risk. On prepayment, the fair value hedge adjustment of the top layer is part of the gain or loss from derecognition of a part of the loan as the result of the early repayment.

The situation illustrated by Illustration 2-9 above, of a hedge of a top layer of a loan, would not often be found in practice as most prepayment options in loan agreements allow, in our experience, for prepayment at the nominal amount (instead of at fair value). Moreover, if a financial asset included an option that allowed prepayment at fair value, that would affect the assessment of the characteristics of the contractual cash flows. That assessment is a part of the classification of financial assets and such a prepayment option might not be consistent with payments that are solely principal and interest (see Chapter 44). However, the ability to designate a top layer in a fair value hedge could be helpful when hedging a group of fixed rate readily transferable financial instruments, see section 2.5.2 below.

As already mentioned above, IFRS 9 does not preclude fair value hedge accounting for layers including a prepayment option that are affected by changes in the hedged risk. However, in order to achieve hedge accounting for such a designation, changes in fair value of the prepayment option as a result of changes in the hedged risk have to be included in the assessment of whether the effectiveness requirements are met and when measuring the change in fair value of the hedged item. Illustration 2-10 illustrates what this means in practice:

Illustration 2-10: Fair value hedge accounting designation using layers with and without prepayment risk

A bank originates a CU10m five-year fixed rate loan with a prepayment option to pay back CU5m at any time at par.

For risk management purposes, the loan is considered together with variable rate borrowings of CU10m. As a result, the bank is exposed to an interest margin risk resulting from the fix-to-floating interest rate mismatch. The bank expects the borrower to prepay CU2m and, therefore, wishes to hedge CU8m only. The bank enters into a five-year pay fixed/receive variable interest rate swap (IRS) with a notional amount of CU8m and designates CU5m of the IRS in a fair value hedge of the benchmark interest rate risk of the CU5m layer of the non-prepayable loan amount. In addition, the bank enters into a five year pay variable/receive fixed interest rate swaption with a notional amount of CU3m that is jointly designated with CU3m of the IRS to hedge the benchmark interest rate risk of the last remaining CU3m of the CU5m prepayable amount of the loan (a bottom layer of the prepayable portion of the loan).

As a result, the CU5m non-prepayable loan amount is adjusted for changes in the fair value attributable to changes in the hedged risk (the fixed rate benchmark interest rate risk of a fixed term instrument). This is also true for the CU3m bottom layer of the prepayable amount, but in addition it must also be adjusted for the effect of changes in the fair value of the prepayment option that exists within the designated CU3m layer, attributable to changes in interest rate risk. The unhedged CU2m top layer remains at amortised cost.

Therefore, the first CU2m of prepayments would have a gain or loss on derecognition determined as the difference between the amortised cost of the prepaid amount and par. For any further prepayments exceeding CU2m, the gain or loss on derecognition would be determined as the difference between the amortised cost including the fair value hedge adjustment and par.

In this case the inclusion of fair value changes in the designated prepayable layer is unlikely to result in ineffectiveness as offset is provided by the CU3m swaption. However, in cases where the prepayment risk is not economically hedged by the hedging instrument, changes in fair value of the prepayment option will lead to ineffectiveness which has the potential to distort the economic relationship. This is discussed in more detail below in Illustration 2-12.

When deciding on which instruments to transact in order to manage the interest rate risk in a prepayable portfolio, an entity will usually consider the likelihood of prepayment in a bottom layer. In particular it will consider whether the risk of prepayment is sufficient to justify the added expense of transacting a hedging instrument that can also be cancelled (e.g., an interest rate swap cancellable at zero cost or an offsetting swaption as described in Illustration 2-10 above). As part of these considerations, it is relatively common that from an economic perspective, an entity might view a bottom layer as having no prepayment risk attached at all and transact a non-cancellable hedging instrument accordingly.

Despite this economic view, the hedge accounting guidance requires consideration of the fair value changes of that bottom layer based on the contractual terms of the hedged item, which would include the prepayment option (see section 7.4.12 below). Hence, for many economic hedges of bottom layers of prepayable hedged items, the changes in the fair values of the hedging instrument and the hedged item will not normally be the same, due to the unit of account required from an accounting perspective. This has the potential to distort the economic relationship between the pre-payable hedged item and the hedging instrument to the extent that hedge accounting might be precluded (see section 6.4.1 below). While it is unlikely that such a risk management objective would be undertaken unless there was an expectation that an economic relationship exists, the existence of the economic relationship would need to be demonstrated, perhaps via the use of a quantitative assessment. Additionally, as the expectation that an economic relationship exists could change over time, especially if the prepayment option looks likely to become in the money, or exercised for any other reason, this expectation would need to be periodically reassessed based on the updated facts and circumstances. Further, any actual ineffectiveness would be measured and recorded in profit or loss (see section 7.4 below).

'Bottom layer' hedging strategies that avoid this source of ineffectiveness can only be applied if the hedged layer is not affected by the prepayment risk. This is best demonstrated by an example (see Illustration 2-11 below).

Illustration 2-11: Hedging a bottom layer (no prepayment risk) of a loan portfolio

A bank holds a portfolio of fixed rate loans with a total nominal amount of CU100m. The borrowers can, at any time during the tenor, prepay 20% of their (original) loan amount at par.

For risk management purposes, the loans are considered together with variable rate borrowings of CU100m. As a result, the bank is exposed to an interest margin risk resulting from the fix-to-floating interest rate mismatch. The bank expects CU20m of loans to be prepaid.

As part of the risk management strategy, the bank decides to hedge a part of the interest margin by entering into a pay fixed/receive variable interest rate swap (IRS). The objective is to hedge 95% of the amount of loans that is not prepayable using an IRS with a notional amount of CU76m (95% of CU80m). The hedged layer does not include a prepayment option. The IRS is designated in a fair value hedge of the interest rate risk of the CU76m bottom layer of the CU100m loan portfolio.

As a result, the bottom layer is adjusted for changes in the fair value attributable to changes in the hedged risk (i.e., benchmark interest rate risk). The extent to which the borrowers exercise their prepayment option (i.e., up to 20% of the original loan) does not affect the hedging relationship. Also, if the bank were to derecognise any of the loans for any other reason, the first CU4m of non-prepayable amount of derecognised loans would not be part of the hedged item (i.e., the CU76m bottom layer). However, if the nominal amount of the loan fell below CU76m, this would start to affect the hedging relationship.

Therefore, while IFRS 9 provides an effective solution for portfolios that feature a bottom layer that is not prepayable, as shown in Illustration 2-11 above, it does not provide an answer for portfolios that are fully prepayable at amount other than at fair value (for example, a residential fixed rate mortgage portfolio). The IASB decided to address hedging of such portfolios in its separate macro hedging project (see section 10 below). Until that project is finalised, entities are allowed to apply the portfolio fair value hedging guidance in IAS 39. [IFRS 9.6.1.3].

Given the current lack of an effective hedge accounting solution within IFRS 9 for portfolios that feature a bottom layer that is prepayable, it is not uncommon for entities to consider alternative 'proxy' hedge accounting designations (see section 6.2.1 below). For example, an entity wishing to hedge an economic bottom layer within a group of items prepayable at par within a fair value hedge could identify specific items within the group (and designate those items only) or designate a percentage of the total as the hedged item. However, it is unlikely that an entity would choose to designate a hedge either way, as both these approaches are still likely to result in ineffectiveness. If specific items within the group were designated in a fair value hedge, and those specific items prepaid, then the designated hedged item would no longer exist, even if there was sufficient 'non-designated' items within the group to cover the amount designated. The issues arising from designation of a proportion are best explained with an example (see Illustration 2-12 below).

Illustration 2-12: Hedging a proportion of a prepayable loan portfolio

A bank holds a portfolio of fixed rate loans with a total nominal amount of CU100m. The borrowers can, at any time, prepay all of their (original) loan amount at par, plus an exit fee. The bank only expects 20% of the original loan amount to be prepaid before maturity.

For risk management purposes, the loans are considered together with variable rate borrowings of CU100m. As a result, the bank is exposed to an interest margin risk resulting from the fix-to-floating interest rate mismatch. The bank expects CU20m of loans to be prepaid.

As part of the risk management strategy, the bank decides to hedge the interest margin by entering into a pay fixed/receive variable interest rate swap (IRS). The objective is to hedge the amount of loans that they do not expect to prepay using an IRS with a notional amount of CU80m. The IRS is designated as a fair value hedge of 80% of the CU100m loan portfolio.

After two years, loans of CU10m are prepaid, which is less than 20% and therefore does not affect the economic hedge in place. However, because of the proportionate designation, this is considered a reduction in the hedged amount for hedge accounting purposes. As a result, the entity now has an IRS of CU80m designated as a hedge of loans of CU72m $([CU100m - CU10m] \times 80\%)$, which will inevitably lead to some ineffectiveness.

Another source of ineffectiveness will be fair value changes attributable to the embedded prepayment option within the loan portfolio, excluding changes in fair value of the embedded prepayment option that clearly arise from factors others than the change in hedged interest rate (see section 7.4.12 below).

A more common approach is for an entity hedging a bottom layer for risk management purposes is to use what is referred to as a proxy hedge, in which the hedged item might be floating rate liabilities and designate the derivatives as hedging them within a cash flow hedge (see section 6.2.1 below). This avoids the inclusion of fair value changes of the embedded prepayment option in the fixed rate loans as a source of potential ineffectiveness, but it does require the identification of sufficient suitable floating rate liabilities.

2.4 The 'sub-benchmark rate issue'

Some financial institutions are able to raise funding at interest rates that are below a benchmark interest rate (e.g., benchmark interest rate minus 15 basis points (bp)). In such a scenario, the entity might wish to remove the variability in future cash flows caused by movements in the benchmark interest rate. IFRS 9 does not allow the designation of a 'full' benchmark risk component (i.e., benchmark rate flat) in this situation, as a component cannot be more than the total cash flows of the entire item. Although historically this is often referred to as the 'sub-LIBOR issue' it is not specific to LIBOR. It will remain an issue for any funding raised below a benchmark rate even now the global Interest Rate Benchmark Reform forced markets to move away from LIBOR as the predominant benchmark interest rate (see the *Supplement: IBOR Reform*). However, as the risk-free rates that will replace LIBOR include a much smaller credit spread, the issue will become much less common in future. [IFRS 9.B6.3.21, IFRS 9.B6.3.22].

Part of the reason for this restriction is that a contractual interest rate is often 'floored' at zero, so that interest will never become negative. The existence of floors can result in accounting and economic outcomes that are inconsistent with hedge accounting. For example, Entity B issues debt at a benchmark rate minus 15bp, but the interest payable is floored at zero. Entity B also enters into a benchmark rate hedging swap with the aim of removing the variability in future cash flows with respect to the benchmark rate, locking in an interest margin. Unless the hedging swap similarly has a floor, then if the benchmark rate decreases below 15bp this would cause cash flow variability for the hedging swap but not for the hedged item. Permitting the designation of a benchmark rate risk component in the hedged item and ignoring the effect of the floor on the variability of the interest cash flows would inappropriately defer hedge ineffectiveness (see section 7.4 below). Consequently, any designated component has to be less than or equal to the cash flows of the entire item. [IFRS 9.B6.3.21, IFRS 9.BC6.225, IFRS 9.BC6.226, IFRS 9.BC6.227, IFRS 9.BC6.228].

In this scenario, the entity could instead designate, as the hedged item, the variability in cash flows of the entire liability (or a proportion of it), but only for changes attributable to the benchmark rate.

[IFRS 9.B6.3.24]. Such a designation excludes any ineffectiveness from changes in the credit risk specific to the borrower, as these are excluded from the hedge relationship, however it will not be perfectly effective. Ineffectiveness could arise as follows in the hedge designation described above:

- For financial instruments that have an interest rate floor of zero in situations in which the forward curve for a part of the remaining hedged term is below 15 basis points. This is because the hedged item will have less variability in cash flows as a result of interest rate changes than a swap without such a floor. In fact, an expectation that the benchmark rate will consistently be below 15 basis points could cause the hedge relationship to fail the effectiveness criteria as there is no economic relationship between the hedged item and hedging instrument. This would preclude hedge accounting entirely (see section 6.4.1 below).
However, if the benchmark rate is above 15 basis points and is not expected to go below it, this source of ineffectiveness would not be expected to arise. The hedged item will have the same cash flow variability as a liability without a floor.
- Ineffectiveness is also likely to occur for example from changes in the time value of the embedded floor in the hedged item, as no offset will arise from the fair value changes of a swap without a floor (see section 7.4.12 below).
- Even if the variability of cash flows in the hedged item and hedging instrument might be the same, the absolute cash flows are not, due to the inclusion of the negative spread in the hedged item. Accordingly, the discounted cash flows will not perfectly offset (see section 7.4 below).
- The discount curve used to discount the hedged cash flows needs to be based on a benchmark rate (see section 7.4.5 below). However, there is a choice between discounting the hedged cash flows at the benchmark rate or at the benchmark rate minus the negative credit spread (15 basis points in the example above), as the guidance is not prescriptive. The negative credit spread would not be updated for changes in the borrower's credit risk as that risk is excluded from the hedge relationship. This is consistent with the general hedge accounting approach of calculating a change in the present value of the hedged item with respect to the hedged risk and not a full fair value. The second option for discounting could improve effectiveness but some ongoing ineffectiveness is likely to remain (see section 7.4 below).

The prohibition on identifying a benchmark rate risk component in a variable instrument priced at a sub-benchmark rate (i.e., a benchmark rate minus a spread) as outlined above, has also some relevance for fixed rate instruments. Let us consider a fixed rate item that is originally priced based on a benchmark rate minus a spread, for example, a fixed-rate financial liability for which the contractual interest rate is initially fixed at 100 basis points below the benchmark rate. It would not be possible to identify the hedged item as having fixed interest cash flows equal to the benchmark, however an entity can designate as the hedged item the entire liability (i.e., principal plus interest equal to the benchmark rate minus 100 basis points) for changes in value attributable to changes in the benchmark rate. [IFRS 9.B6.3.23].

The negative interest rate environment in some countries has further implications on the designation of risk components in connection with the sub-benchmark issue (see section 2.4.2 below).

While the example in the standard uses LIBOR as the benchmark rate component, it is clear that the requirement relates not just to financial items in general, but is a general prohibition on the cash flows of hedged risk components being larger than the cash flows of the entire hedged item. This means that the sub-LIBOR issue is also applicable to non-financial items where the contract price is linked to a benchmark price minus a differential. This is best demonstrated using an example derived from the application guidance of IFRS 9 (see Illustration 2-13 below).

Illustration 2-13: Sub-benchmark rate issue - selling crude oil at below benchmark price

An entity has a long-term sales contract to sell crude oil of a specific quality to a specified location. The contract includes a clause that sets the price per barrel at West Texas Intermediate (WTI) minus USD10 with a minimum price of USD30. The entity wishes to hedge the WTI benchmark price risk by entering into a WTI future. As outlined above, the entity cannot designate a 'full' WTI component, i.e., a WTI component that ignores the price differential and the minimum price.

However, the entity could designate the WTI future as a hedge of the entire cash flow variability under the sales contract that is attributable to the change in the benchmark price. When doing so, the hedged item would have the same cash flow variability as a sale of crude oil at the WTI price (or above), as long as the forward price for the remaining hedged term does not fall below USD40. [IFRS 9.B6.3.25].

Where the hedged item has the same cash flow variability as the hedging instrument there could be an expectation that the hedge relationship will meet the effectiveness criteria. However, any ineffectiveness needs to be measured and recorded in profit or loss (see section 7.4 below).

In some cases, the contract price might not be defined as a benchmark price minus a fixed differential but as a benchmark price plus a pricing differential (the 'basis spread') that is sometimes positive and sometimes negative. The market structure could reveal that items are priced that way and there might even be derivatives available for the basis spread (i.e., basis swaps, for example the benchmark gas oil crack spread derivative which is a derivative for the price differential between crude oil and gas oil which reflects the refining margin [IFRS 9.B6.3.10(c)(i)]). Similar to Illustration 2-13 above, an entity could not designate the benchmark price component as the hedged item given that the cash flows of the benchmark price component could be more than the total cash flows of the entire item. Unfortunately, the standard does not provide any guidance as to how an entity might assess whether the basis spread could be negative or not. For example, it is not clear whether an entity is only required to look at the forward benchmark prices or whether it is required to consider all reasonably possible scenarios. The use of 'reasonably possible scenarios' in other places in IFRS 9 might indicate the latter.

A related question is whether the entity could designate the entire cash flow variability that is attributable to changes in only the benchmark price risk (as the entity alternatively does as shown in Illustration 2-13 above) if that risk is a non-contractually specified risk component. This assessment is likely to be similar to whether a non-contractually specified risk component is separately identifiable and reliably measurable (as outlined in section 2.2.3 above), which would be required in order to determine the variability of the entire cash flows with respect to changes in the benchmark price.

However, the presence of a spread that is sometimes negative could make this assessment more difficult. An entity needs to prove that the benchmark price cash flows plus or minus the spread make up the total cash flows. This might be the case, for example, if it can be proven that there are quality differences, such that the benchmark price is sometimes of better quality and sometimes worse than the hedged exposure. On the other hand, if the basis spread switches between positive and negative because of individual supply and demand drivers of either the benchmark price or the price of the hedged exposure, this could indicate that the benchmark price is not implicit in the fair value or cash flows of the hedged exposure. To illustrate this with an example, we could take WTI and Brent crude oil prices. While both prices might be highly correlated, WTI could not be identified as a benchmark price component in Brent because both prices have their own supply and demand drivers. Furthermore, it would not be possible to determine whether either WTI is a risk component of Brent or *vice versa*, which demonstrates that there is no risk component that can be designated in a hedge relationship. In that case, hedge accounting would only be permitted if the full cash flows were designated for all changes in the contract price, and assuming the other eligibility requirements are met.

2.4.1 Late hedges of benchmark rate portions of fixed rate instruments

There is no requirement in IFRS 9 for hedge accounting to be designated on initial recognition of either the hedged item or the hedging instrument. [IFRS 9.B6.5.28]. In particular, it is not uncommon for risk management and/or hedge accounting to be applied sometime after initial recognition of the hedged item. This is often referred to as a 'late hedge'. There is no additional guidance in IFRS 9 on how to apply hedge accounting to 'late hedges' over and above the usual criteria. However, the identification of eligible risk components in fixed rate hedged items in late hedges can be problematic.

An example of the difficulties of such a designation is discussed in the application guidance to IFRS 9 with respect to a fixed rate financial instrument that is hedged sometime after its origination using an on market derivative, and interest rates have changed in the meantime, such that the fixed rate on the instrument is now below the benchmark rate i.e., the fixed rate in the hedging derivative. Despite the requirement for risk components to be less than or equal to the total cash flows of the entire item, in this case it could be possible for the entity to designate a risk component equal to the benchmark rate that is higher than the contractual rate paid on the item. This is provided that the benchmark rate is still less than the effective interest rate (yield) calculated as if the instrument had been purchased on the day it was first designated as the hedged item. [IFRS 9.B6.3.21, IFRS 9.B6.3.23]. This is illustrated below.

Illustration 2-14: Hedge of a portion of an existing fixed rate financial asset following a rise in interest rates

Company B originates a fixed rate financial asset of CU100 that has an effective interest rate of 6% at a time when the benchmark rate is 4%. B begins to hedge that asset sometime later using an on market derivative when the benchmark rate has increased to 8% and the fair value of the asset has decreased to CU90 (reflecting an effective yield of 9.5%). The asset matures in four years' time. The future annual cash flows on the financial asset are given below.

	1	2	3	4
Future cash flows on existing fixed rate financial asset	CU6	CU6	CU6	CU106

Because the current benchmark rate of 8% is less than this current effective yield of 9.5%, the entity can designate a benchmark rate component of 8% as a risk component of the 9.5% effective yield. If the entity does designate a benchmark rate component of 8%, the hedged cash flows will consist partly of the contractual interest cash flows and partly of the difference between the net present value discounted at the hedged risk of 8% (CU93) and the amount repayable on maturity (CU100). [IFRS 9.B6.3.23]. This is further demonstrated in the table below.

Effective Yield	Asset calculation basis	Asset value
Original EIR at 6%	Amortised cost	CU100
Current effective yield at 9.5%	Current fair value	CU90
Hedged risk at 8%	Net present value of the hedged item discounted at 8%	CU93

The guidance illustrated in Illustration 2-14 above will assist entities in designating hedges in a way that significantly reduces ineffectiveness. However, some ineffectiveness is still likely to arise if the hedging instrument has a fixed rate that reflects the 8% benchmark rate. This is because the timing of the 8% cash flows from the hedging instrument (i.e., an interest rate swap with a fixed leg at 8%) is unlikely to match fully the timing of the hedged cash flows, which are represented by the actual future contractual coupons (e.g., 6%) and an amount of principal payable on maturity.

It is also not uncommon for an existing derivative to be designated as a hedging instrument of new or existing fixed rate hedged items. It is likely that the existing hedging instrument will have a non-zero fair value on designation and will have a fixed rate that is different to the prevailing benchmark rate for the remaining term of the hedged item. The ability to designate a risk component and/or a nominal amount of the fixed rate hedged item can be helpful in achieving fair value hedge accounting. [IFRS 9.6.3.7]. This is illustrated below.

Illustration 2-15: Hedge of a portion of a fixed rate financial liability with an existing derivative with a non-zero fair value

Company C issues new debt of CU200m fixed rate debt at par, the pricing of which was determined based on the prevailing benchmark rate of 1.5%, plus a credit spread of 200bp resulting in a fixed coupon of 3.5%. Company C identifies an existing CU200m receive fixed 2%, pay floating interest rate swap with the same residual maturity as the issued debt. The existing swap enables Company C to reduce the variability in the fair value of the issued debt with respect to the benchmark rate, consistent with their risk management.

The benchmark rate is a separately identifiable and reliably measurable risk component of the fixed rate debt, considering the market structure within which it was issued (see section 2.2.3.A above). Hence it is possible for Company C to designate the fair value hedge with respect only to changes in the benchmark rate.

It is also possible for Company C to identify a nominal component of the fixed rate debt, i.e., a specified part of the fixed rate debt (see section 2.3.1 above). [IFRS 9.6.3.7(c)]. In that case Company C could choose to designate the hedged item to be the full CU200m principal of the fixed rate debt, but only an amount equivalent to a 2% coupon of each actual fixed rate 3.5% interest coupon, for changes in fair value with respect to the benchmark rate.

Such a strategy has the benefit of improving offset of fair value changes in both the hedged item and the hedging instrument due to the benchmark rate, as both have a fixed rate of 2%. This could result in lower levels of ineffectiveness.

However, as fair value hedge accounting for the hedged item only reflects the cumulative fair value changes with respect to the hedged risk since designation, care would need to be taken to ensure an appropriate amortisation approach was applied such that the fair value hedge adjustment is fully amortised by maturity of the hedge relationship (see section 7.1.2 below).

This approach is only possible because the fixed rate on the interest rate swap (i.e., 2%) is less than the actual coupon on the fixed rate debt (i.e., 3.5%). If the swap rate was higher (e.g., 4%) then it would not be possible to designate the full CU200m principal of the fixed rate debt plus a 4% coupon as the hedged item, as any designated component has to be less than or equal to the cash flows of the entire item. [IFRS 9.B6.3.21].

Company C could instead choose to designate the hedged item to be the full CU200m principal of the fixed rate debt but with an amount equivalent to a 1.5% coupon (i.e., the prevailing benchmark rate) for changes in fair value with respect to the benchmark rate. In that case some ineffectiveness would arise but the amortisation of the fair value hedge adjustment over the life of the hedge relationship is simpler.

This designation strategy would not work if hedging a floating rate instrument with an existing derivative with a non-zero fair value as it is not possible to identify an off-market risk component in a cash flow hedge to match an off-market hedging instrument (see section 7.4.3 below).

2.4.2 Negative interest rates

Some countries have, or have had negative interest rate environments, for example Switzerland, Japan and certain countries in the Eurozone. The requirements in consideration of whether a benchmark rate is an eligible risk component in a financial instrument are the same irrespective of whether the benchmark rate is positive or negative (see sections 2.2.2 and 2.2.3.A above). The following Illustration shows this for a fair value hedge.

Illustration 2-16: Negative interest rates and fair value hedges

Assume the following scenarios:

- (a) Bank A enters into a €1 million loan to a corporate at a fixed coupon of 3.5%. The coupon has been determined considering the negative Euro Short-Term Rate (€STR) rate (the benchmark rate) of minus 0.15% plus a credit spread of 3.65%.
- (b) Bank B acquires debt securities in the secondary market, issued by a highly rated corporate entity, with a €1 million notional and fixed coupon of 3.5%. In this fact pattern the debt was issued some years ago when benchmark interest rates were much higher. The purchase price of the debt is €1.185 million which results in an effective interest rate of minus 0.18%, consisting of the negative €STR rate (the benchmark rate) when the debt is acquired of minus 0.15% and a credit spread of minus 0.03%.

Both Bank A and Bank B want to hedge the fixed rate benchmark rate component and each enter into an interest rate swap with a €1 million principal, paying fixed minus 0.15% and receiving €STR. The banks wish to designate the benchmark rate component in a fair value hedge for changes in €STR.

In scenario a) it seems acceptable for the bank to designate the benchmark rate risk component because:

- It is included in the pricing of the hedged item and is thought to meet the separately identifiable and reliably measurable criteria (see section 2.2.3.A above).
- The benchmark rate can be positive or negative, therefore the cash flows representing that benchmark rate can also be positive or negative, even if they are part of overall positive cash flows (which is similar to a benchmark rate component of 4% hedging the benchmark rate risk in a coupon of 5%, except that the benchmark rate is negative in this case).

And

- The benchmark rate cash flows are less than the cash flows in the hedged items (i.e., minus 0.15% which is less than 3.5%).

We would find it difficult to reach the same conclusion for scenario b) as the benchmark rate is higher than the effective interest rate (i.e., minus 0.15% which is greater than minus 0.18%). [IFRS 9.B6.3.23]. This is consistent with the fact that if a debt instrument were to be issued at par bearing a coupon of minus 0.18%, which included a credit spread of minus 0.03% when the benchmark rate was minus 0.15%, it would not be possible to identify a benchmark rate component for hedge accounting purposes. [IFRS 9.B6.3.21].

In both scenarios, the banks would not be permitted to designate a payment of minus 0.15% of the principal as an eligible component of a receipt of a 3.5% coupon. [IFRS 9.6.3.7(b)]. This is because it is difficult to argue that a payment of a negative 0.15% of the principal is a portion of a receipt of 3.5% of that principal. However, this is not that relevant in scenario a) as it would be possible to designate a separately identifiable benchmark rate component in the total cash flows, as noted above.

Notwithstanding the above, in both cases, the banks can designate all the cash flows in the financial asset for changes in the benchmark rate, although this is likely to result in some ineffectiveness. [IFRS 9.B6.3.21].

Illustration 2-16 above relates to fair value hedges of fixed rate instruments. When applying cash flow hedge accounting of interest rate risk in a negative interest rate environment, further complications arise if an instrument (typically the hedged item) is floored at zero. If there is an 'in the money floor' in the hedged item, such that no interest is currently payable or expected to be payable in the future, then there is no cash flow variability with respect to the hedged risk, hence cash flow hedge accounting is precluded (see sections 5 and 5.2 below). [IFRS 9.6.5.2].

Further, in a negative interest rate environment if the hedged item contains a floor at zero, and no such floor exists in the hedging instrument, even if there was an expectation that interest rates might become positive again within the term of the hedge relationship, demonstrating that an economic relationship exists between the hedged item and hedging instrument could be tricky (see section 6.4.1 below), in which case hedge accounting would cease. [IFRS 9.6.4.1(c)(i)]. This is because until interest rate become positive again there is no variability in the hedged cash flows from changes in interest rates (i.e., they are fixed at zero), but cash flows on the floating leg of the hedging instrument will reflect all changes in the interest rate. In fact, such a strategy would result in increased cash flow variability as a result of the risk management activities. The issues arising from the existence of floors within a negative interest rate environment are similar to those within sub-benchmark rate instruments (see section 2.4 above).

2.5 Groups of items

2.5.1 General requirements

Extract from IFRS 9

- 6.6.1** A group of items (including a group of items that constitute a net position; see paragraphs B6.6.1-B6.6.8) is an eligible hedged item only if:
- (a) it consists of items (including components of items) that are, individually, eligible hedged items;
 - (b) the items in the group are managed together on a group basis for risk management purposes; and
 - (c) in the case of a cash flow hedge of a group of items whose variabilities in cash flows are not expected to be approximately proportional to the overall variability in cash flows of the group so that offsetting risk positions arise:
 - (i) it is a hedge of foreign currency risk; and
 - (ii) the designation of that net position specifies the reporting period in which the forecast transactions are expected to affect profit or loss, as well as their nature and volume (see paragraphs B6.6.7-B6.6.8).

[IFRS 9.6.6.1]

Illustration 2-17: Hedging a portfolio of shares

An entity holds a portfolio of shares of Swiss companies that replicates the Swiss Market Index (SMI). The entity elected to account for the shares at fair value through other comprehensive income without subsequent reclassification to profit or loss, as allowed by IFRS 9 (see Chapter 44). The entity decides to lock in the current value of the portfolio by entering into corresponding SMI futures contracts.

The individual shares would be eligible hedged items if hedged individually (using derivatives on the price of each share). As the objective of the portfolio is to replicate the SMI, the entity can also demonstrate that the shares are managed together on a group basis. The entity also assesses the compliance with the criteria for hedge accounting (see section 6 below). Consequently, the entity designates the SMI futures contracts as the hedging instrument in a hedge of the fair value of the portfolio. As a result, the gains or losses on the SMI futures are accounted for in OCI (without subsequent reclassification to profit or loss) in the same manner as the shares, thus eliminating the accounting mismatch (see section 2.6.3 below). [IFRS 9.6.5.3].

Whether the items in the group are managed together on a group basis is a matter of fact, i.e., it depends on an entity's behaviour and cannot be achieved by mere documentation.

The IFRS 9 eligibility criteria for groups of items for hedge accounting also permits designation of net positions if an entity hedges on a net basis for risk management purposes. [IFRS 9.BC6.435]. Whether an entity hedges in this way is a matter of fact (not merely of assertion or documentation). Hence an entity cannot apply hedge accounting on a net basis solely to achieve a particular accounting outcome if that would not reflect its risk management approach. [IFRS 9.6.6.1(b), IFRS 9.B6.6.1]. In addition, there are some further restrictions for cash flow hedges of net positions (see section 2.5.3 below). [IFRS 9.BC6.436].

IFRS 9 also contains special presentation requirements when hedging net positions, which are discussed in sections 2.5.3 and 9.3 below.

2.5.2 Hedging a component of a group

A group designation can also consist of a component of a group of items, such as a layer component of a group. A component could also be a proportion of a group of items, such as 50% of a fixed rate bond series with a total volume of CU100 million. Whether an entity designates a layer component or a proportionate component depends on the entity's risk management objective. [IFRS 9.6.6.1, IFRS 9.6.6.2].

Extract from IFRS 9

- 6.6.3 A layer component of an overall group of items (for example, a bottom layer) is eligible for hedge accounting only if:
- (a) it is separately identifiable and reliably measurable;
 - (b) the risk management objective is to hedge a layer component;
 - (c) the items in the overall group from which the layer is identified are exposed to the same hedged risk (so that the measurement of the hedged layer is not significantly affected by which particular items from the overall group form part of the hedged layer);
 - (d) for a hedge of existing items (for example, an unrecognised firm commitment or a recognised asset) an entity can identify and track the overall group of items from which the hedged layer is defined (so that the entity is able to comply with the requirements for the accounting for qualifying hedging relationships); and
 - (e) any items in the group that contain prepayment options meet the requirements for components of a nominal amount (see paragraph B6.3.20).

[IFRS 9.6.6.3].

The benefits of identifying a layer component, as discussed in section 2.3 above, are relevant when applied to a group of items. In fact, the bottom layer hedging strategy discussed in Illustration 2-11 in section 2.3.2 above is, in fact, a designation of a component of a group. The following Illustration provides a different example of designating a component of a group, this time a top layer.

Illustration 2-18: Hedging a top layer of a portfolio of financial liabilities

A bank completes a bond issuance of CU50 million that is made up of 50,000 fixed rate bonds with a face value of CU1,000 each. The bank expects that it will repurchase up to CU10 million of the issue before maturity. Therefore, it chooses to transact a receive fixed/pay variable interest rate swap with a notional amount of CU10 million, in order to hedge the benchmark rate component of the fair value interest rate risk of the volume that is expected to be repurchased. From an economic perspective, that hedge would allow repurchases of up to CU10 million total face value for which the gain or loss from changes in the benchmark rate would be compensated by the gain or loss on the swap. However, this can only be reflected in the accounting if the entity designates a CU10 million top layer. The entity would revalue the first CU10 million of face value of the bond issue expected to be repurchased for changes in the benchmark rate risk, and would include a fair value hedge gain or loss when determining the gain or loss on derecognition of the first CU10 million of bonds when they are repurchased.

If it was not permitted to designate a layer of a group of items, entities would in such cases either have to identify individual items within the group and designate them on a standalone basis, or prorate the fair value hedge gain or loss to the entire bond issue volume, as discussed in section 2.3.2 above. The IASB believes this would result in arbitrary accounting results and decided to allow a layer component designation for a group of items. [IFRS 9.BC6.438, IFRS 9.BC6.439].

Designation of a layer component which includes a prepayment option is discussed in section 2.3.2 above. Based on the information provided, the top layer in Illustration 2-18 above would meet the criteria in order for a top layer to be designated.

Extract from IFRS 9

- B6.6.12 A hedging relationship can include layers from several different groups of items. For example, in a hedge of a net position of a group of assets and a group of liabilities, the hedging relationship can comprise, in combination, a layer component of the group of assets and a layer component of the group of liabilities.

[IFRS 9.B6.6.12].

The hedge of a net position of a group of assets and a group of liabilities is discussed in section 2.5.1 above and section 2.5.3 below.

2.5.3 Cash flow hedge of a net position

Many entities are exposed to foreign currency risk arising from purchases and sales of goods or services denominated in foreign currencies. Cash inflows and outflows occurring on forecast transactions in the same foreign currency are often economically hedged on a net basis, as illustrated in the below example.

Illustration 2-19: Economic 'natural hedge' of foreign currency cash flows

An entity with GBP as its functional currency anticipates foreign currency denominated sales of USD100 in 12 months and also intends to purchase fixed assets of USD80 in 12 months. USD80 of the cash inflows of the forecast sales are economically hedged together with the cash outflows for the forecast purchase of the fixed assets. A single foreign currency forward contract to sell USD20 in 12 months is transacted to hedge the net position arising from the sales and purchases.

In the case of a cash flow hedge of a group of items whose variabilities in cash flows are not expected to be approximately proportional to the overall variability in cash flows of the group so that offsetting or net risk positions arise, designation is only permitted for a hedge of foreign currency risk. Said differently, designation of a net position in a cash flow hedge is limited to hedges of foreign currency risk under IFRS 9. [IFRS 9.6.6.1(c), IFRS 9.B6.6.7, IFRS 9.BC6.455].

The standard mechanics of cash flow hedge accounting cannot accommodate a hedged net position whose gross cash flows affect profit or loss in different periods (see section 7.2 below). Applying standard cash flow hedge accounting to Illustration 2-19 above, the gain or loss accumulated in other comprehensive income (OCI) on the USD20 of hedging instrument would be reclassified to profit or loss when the revenue transaction occurs. However, this will only offset the gain or loss on USD20 of the USD100 hedged revenue while the remaining revenue of FC80 and the fixed asset purchase of USD80 (i.e., the economic hedge) would still be measured at the spot rate. This would result in the bottom line profit for the period(s) not reflecting the economic hedge.

IFRS 9 amends the standard cash flow hedge accounting for such a net position in that the foreign currency gain or loss on the USD80 revenue cash flows that affect profit or loss in the earlier period must be carried forward to offset the foreign currency gain or loss on the fixed asset purchase cash flows that will affect profit or loss in later periods. This is achieved by deferring the gain or loss on the natural hedge in OCI, with a reclassification to profit or loss once the offsetting cash flows affect profit or loss (see section 9.3.1 and Illustration 2-20 below).

However, the gross transactions that make up the net position are recognised when they arise and will be measured at the spot foreign currency rate ruling at that time. They are not adjusted to reflect the result of the hedge. The whole impact of hedge accounting must be presented in a separate line item in profit or loss. [IFRS 9.6.6.4].

This separate line item includes:

- The reclassification adjustment for gains or losses on the hedge of the net position
- The gain or loss on the natural hedge, with the counter-entry being recognised in OCI
- And
- The later reclassification adjustment of the gain or loss on the natural hedge from OCI to profit or loss. [IFRS 9.B6.6.15].

The rather complicated accounting described above is best illustrated using an example:

Illustration 2-20: Cash flow hedge of a foreign currency net position

An entity having CAD as functional currency anticipates sales of GBP100m in 12 months and also plans a major capital expenditure (fixed assets) of GBP80m in 12 months. The anticipated sales and capital expenditure (i.e., the group of forecast transactions) are designated as the hedged item and the resulting net position is hedged with a forward contract to sell GBP20m in 12 months. The fixed assets will be depreciated on a straight-line basis over eight years. For simplicity, assume the spot rate equals the forward rate.

GBP/CAD spot rate

At inception of the hedge (beginning of year 1)	1.50
After 12 months (end of year 1)	1.60

The entity would record the following journal entries (amounts in millions):

Year 1	CAD	CAD
Dr Other comprehensive income	2	
Cr Hedging derivative		2

To recognise the fair value loss from the hedging instrument in the statement of financial position and the cash flow hedge reserve ($\text{GBP}20 \times [1.50 - 1.60]$).

Dr	Cash	160	
	Cr	Revenue from sales	160

To account for the sales volume of GBP100 at the current spot rate of 1.60 (GBP100 × 1.60).

Dr	Property, plant and equipment	128	
	Cr	Cash	128

To account for the purchase of GBP80 fixed assets at the current spot rate of 1.60 (GBP80 × 1.60).

Dr	Hedging derivative	2	
	Cr	Cash	2

To account for the settlement of the forward contract.

Dr	Net position hedging gains/losses	2	
	Cr	Other comprehensive income	2

To reclassify the cash flow hedge reserve from OCI to profit or loss.

Dr	Net position hedging gains/losses	8	
	Cr	Other comprehensive income	8

To defer the natural hedge gain from profit or loss to OCI (GBP80 × [1.60 - 1.50]).

The net profit for the period is CAD 150, which represents the sale of GBP100 at the hedged rate of 1.50 (albeit presented in two different line items).

Years 2 to 9		CAD	CAD
Dr	Depreciation	16	
	Cr	Property, plant and equipment	16
Dr	Other comprehensive income	1	
	Cr	Net position hedging gains/losses	1

To reclassify part of the deferred gain from OCI to profit or loss (CAD 8 × 12.5%).

The net loss for each period is 15, which represents depreciation (at 12.5%) of a fixed asset of GBP80 purchased at the hedged rate of 1.50.

Overview

Income statement (CAD)										
	Y1	Y2	Y3	Y4	Y5	Y6	Y7	Y8	Y9	Total
Revenue from sale of goods	160									160
Depreciation		(16)	(16)	(16)	(16)	(16)	(16)	(16)	(16)	(128)
Net position hedging gains/losses	(10)	1	1	1	1	1	1	1	1	(2)
Profit for the period	150	(15)	(15)	(15)	(15)	(15)	(15)	(15)	(15)	30
Statement of financial position (CAD)										
	Y1	Y2	Y3	Y4	Y5	Y6	Y7	Y8	Y9	
Cash	30	30	30	30	30	30	30	30	30	
Property, plant and equipment	128	112	96	80	64	48	32	16	-	
Hedging reserve (OCI)	(8)	(7)	(6)	(5)	(4)	(3)	(2)	(1)	-	

The transactions within a net position still must be measured at their spot rates, while the effect of the hedge is presented in a separate line item. [IFRS 9.B6.6.15]. In other words, although an entity could be economically hedged from a bottom line (or net) perspective, volatility will still arise in the amounts reported for the individual hedged transactions (on a gross basis), and it is only the bottom line of profit or loss that will reflect the benefits of the hedge.

For a net position to qualify for cash flow hedge accounting the hedge documentation has to include, for each type of item within the net position, its amount and nature as well as the reporting period in which it is expected to affect profit or loss. This is expected to be a relatively detailed record of what makes up the net position and how it will impact profit or loss, including the depreciation profile, if relevant. [IFRS 9.6.6.1(c)(ii), IFRS 9.B6.6.7, IFRS 9.B6.6.8].

2.5.4 Nil net positions

IFRS 9 also addresses hedges of nil net positions. This refers to when entities hedge a group of items where the hedged items themselves fully offset the risk that is managed. An example would be similar to the scenario illustrated by Illustration 2-19 above but where the entity anticipates sales of GBP100m in 12 months and also plans a major capital expenditure of GBP100m in 12 months. Hedge accounting for a net nil position is possible, applying the same treatment as for hedges of net positions in section 2.5.1 and section 2.5.3 above, however there are some additional requirements that must be met.

Extract from IFRS 9

- 6.6.6 When the hedged item is a group that is a nil net position (ie the hedged items among themselves fully offset the risk that is managed on a group basis), an entity is permitted to designate it in a hedging relationship that does not include a hedging instrument, provided that:
- (a) the hedge is part of a rolling net risk hedging strategy, whereby the entity routinely hedges new positions of the same type as time moves on (for example, when transactions move into the time horizon for which the entity hedges);
 - (b) the hedged net position changes in size over the life of the rolling net risk hedging strategy and the entity uses eligible hedging instruments to hedge the net risk (ie when the net position is not nil);
 - (c) hedge accounting is normally applied to such net positions when the net position is not nil and it is hedged with eligible hedging instruments; and
 - (d) not applying hedge accounting to the nil net position would give rise to inconsistent accounting outcomes, because the accounting would not recognise the offsetting risk positions that would otherwise be recognised in a hedge of a net position.

[IFRS 9.6.6.6].

2.6 Other eligibility issues for hedged items

2.6.1 Highly probable

Forecast transactions (or a component thereof) can only be eligible hedged items if they are highly probable of occurring (see section 2.1 above). [IFRS 9.6.3.3]. The term 'highly probable' is not defined in IFRS 9 but is often interpreted to have a much greater likelihood of happening than 'more likely than not'. The Implementation Guidance within IAS 39 contained some guidance as to how the term highly probable is applied within the context of hedge accounting and, this guidance can be considered relevant for IFRS 9 hedge accounting. The IAS 39 guidance indicates that an assessment of the likelihood that a forecast transaction will take place is not based solely on management's intention, it should be supported by observable facts and the attendant circumstances. In such an assessment, an entity should consider the following:

- The frequency of similar past transactions
 - The financial and operational ability of the entity to carry out the transaction
 - Whether substantial commitments of resources have been made to a particular activity
 - The extent of loss or disruption of operations that could result if the transaction does not occur
 - The likelihood that transactions with substantially different characteristics might be used to achieve the same business purpose
- And
- The entity's business plan [IAS 39.F.3.7]

Although, by the nature of a forecasted transaction, the terms and timing of the transaction may not be known with certainty, if the key terms cannot be estimated with reasonable specificity then it may be difficult to determine that the forecasted transaction is indeed highly probable. [IAS 39.F.3.11]. Reasonable specificity in terms of identifying a forecast transaction is necessary both in order to measure any ineffectiveness from the hedge relationship (see section 7.4 below) and also to determine whether and when the documented hedged item occurs (see section 8.3 below).

In March 2019, the IFRS IC discussed the application of the highly probable requirement with respect to a specific derivative (a load following swap) designated as a hedging instrument.⁶ In a load following swap the notional amount of the derivative designated as a hedging instrument varies depending on the outcome of the hedged item (e.g., forecast energy sales). As part of that specific discussion, the IFRS IC observed more generally that the terms of the hedging instrument do not affect the highly probable assessment because the highly probable requirement is applicable to the hedged item (see section 6.3.3 below). For example, an entity that wishes to hedge the foreign currency risk of a future business combination, can only achieve hedge accounting once the business combination itself is highly probable (see section 2.6.4 below). This is the case even if the hedging instrument is a deal contingent foreign currency contract, such that if the business combination does not go ahead, the foreign currency contract is terminated with no cash settlement.

In addition, an entity might also need to consider the impact of wider industry and business drivers as to whether cash flows are highly probable or not. For example:

- Whether forecast cash flows in a subsidiary that is due to be sold can be considered highly probable in the parent's consolidated financial statements (see section 7.2.4 below)
- Or
- If a designated benchmark interest rate is no longer expected to exist, whether forecast cash flows linked to that benchmark rate can be highly probable (see the *Supplement: IBOR Reform*)

The length of time until a forecast transaction is projected to occur is also a factor. Other factors being equal, the more distant a forecast transaction is, the less likely it is that it would be considered highly probable and the stronger the evidence required to determine that it is highly probable.

For example, a transaction forecast to occur in 5 years will often be less likely to occur than a transaction forecast to occur in one year. However, forecast interest payments for the next 20 years on variable rate debt would typically be highly probable if supported by an existing contractual obligation.

An entity might also need to consider the credit risk associated with the counterparty to a forecast transaction. Even though a forecast transaction does not involve credit risk, depending on the possible counterparties for the anticipated transaction, the credit risk that affects them can indirectly affect the assessment of whether the forecast transaction is highly probable or not (see section 6.4.2.B below).

In addition, other factors being equal, the greater the physical quantity or future value of the forecast transaction, in proportion to the entity's total transactions of the same nature, the less likely it is that the transaction would be considered highly probable. For example, less evidence generally would be needed to support forecast highly probable sales of 100,000 units in the next month than 950,000 units in that month, when recent sales have averaged 950,000 for the past 3 months.

A history of having designated hedges of forecast transactions and then determining that they are no longer expected to occur would call into question both an entity's ability to predict forecast transactions accurately and the propriety of using hedge accounting in the future for similar transactions. [IAS 39.F.3.7]. However, the standard contains no prescriptive 'tainting' provisions in this area. Therefore, entities are not automatically prohibited from using cash flow hedge accounting if a forecast transaction fails to occur. Instead, whenever such a situation arises the particular facts, circumstances and evidence must be assessed to determine whether doubt has, in fact, been cast on an entity's ongoing hedging strategies.

It is also explained in the IAS 39 Implementation Guidance that cash flows arising after the prepayment date on an instrument that is prepayable at the issuer's option could be highly probable for a group or pool of similar assets for which prepayments can be estimated with a high degree of accuracy, e.g., mortgage loans, or if the prepayment option is significantly out of the money. In addition, the cash flows after the prepayment date may be designated as the hedged item if a comparable option exists in the hedging instrument (see section 7.4.12 below). [IAS 39.F.2.12].

Further discussion on the hedge documentation requirements for designated highly probable forecast transactions is given in section 6.3.3 below.

⁶ [IFRIC Update](#), March 2019, available on the IFRS Foundation's website.

2.6.2 Hedged items held at fair value through profit or loss

It does not immediately appear that it would be useful to designate a hedged item that is measured at fair value through profit or loss in a hedge relationship. However, because IFRS 9 could require certain variable rate assets to be measured at fair value through profit or loss (see Chapter 44), designation as the hedged item in a cash flow hedge relationship could be desirable. Although the variable hedged item would be measured at fair value through profit or loss, an entity could still seek to hedge the variability of cash flows by entering into a hedging derivative. Because of the variable nature of the hedged item, such instruments might not be significantly exposed to changes in fair value caused by movements in the hedged risk whereas the hedging derivative will be. In this instance, application of cash flow hedge accounting facilitates deferral of fair value changes in the hedging derivative to the cash flow hedge reserve, which could better reflect the risk management strategy.

An additional reason that a hedge designation might be desirable for hedged items measured at fair value through profit or loss could be in order to achieve costs of hedging treatment for the time value, forward or foreign currency basis element of the hedging instrument (see section 7.5 below). For any such designation care would need to be taken that the usual qualifying criteria for hedge accounting are met (see section 6 below).

IFRS 9 provides confirmation that cash flow hedge accounting is not prohibited for all hedged items measured at fair value through profit or loss. It gives as an example of an eligible cash flow hedge where an entity uses a swap to change floating rate debt to fixed rate, even if the debt is measured at fair value. This is because there is a systematic way in which the cash flow hedge reserve can be reclassified, i.e., in the same way interest payments occur on the hedged instrument. A contrasting example is given of a forecast purchase of an equity instrument that, once acquired, will be accounted for at fair value through profit or loss. This is mentioned as an example of an item that cannot be the hedged item in a cash flow hedge, because any gain or loss on the hedging instrument that would be deferred could not be appropriately reclassified to profit or loss during a period in which it would achieve offset. [IFRS 9.B6.5.2].

As well as providing confirmation that cash flow hedge accounting is not precluded for hedged items measured at fair value through profit or loss, the guidance in IFRS 9.B6.5.2 also appears to introduce an additional requirement that there is a systematic way in which the cash flow hedge reserve can be reclassified for such a hedge. [IFRS 9.B6.5.2]. Therefore, it seems that cash flow hedge accounting is not only precluded for equity instruments but also for any non-financial hedged items measured at fair value through profit or loss. The same difficulty with respect to a lack of a systematic way in which the cash flow hedge reserve would be reclassified also exists in a cash flow hedge of a forecast transaction to purchase equity instruments or non-financial hedged items that will be measured at fair value through profit or loss.

In addition, the reason why the instrument is measured at fair value through profit or loss will also be a factor in determining whether an instrument measured at fair value through profit or loss will be an eligible hedged item or not. Classification of an item at fair value through profit or loss could be because such an item is held for trading, managed on a fair value basis, designated as measured at fair value through profit or loss using the fair value option or because the contractual terms of the financial asset give rise on specified dates to cash flows that are not solely payments of principal and interest on the principal amount outstanding (see Chapter 44). We discuss the eligibility of such instruments measured at fair value through profit or loss in the paragraphs below.

2.6.2.A Hedged items managed on a fair value basis

If an instrument is part of a portfolio that is managed on a fair value basis, there is a question as to whether it can be an eligible hedged item or not.

How we see it

For a portfolio of financial assets that is managed and whose performance is evaluated on a fair value basis, an entity is primarily focused on fair value information and uses that information to assess the assets' performance and to make decisions. In our view, if the hedging instrument is also part of the same portfolio (or business model), and the entity has by definition determined that fair value is the most appropriate measure for that portfolio, then this would be inconsistent with the idea of cash flow hedging, whereby part of the fair value movements would be recorded in other comprehensive income, separately from the remaining fair value movements that would be recorded in profit or loss. We therefore believe cash flow hedge accounting would not ordinarily be appropriate in this scenario.

It would similarly be inconsistent with the idea of hedge accounting if forecast transactions that will be managed on a fair value basis when acquired, were part of a hedge relationship to hedge cash flow variability in the price prior to acquisition.

In the same way, it would not be appropriate to designate a financial asset managed on a fair value basis as a hedged item in a fair value hedge, in order to defer fair value changes in the time, forward or foreign currency basis element of the hedging instrument as a cost of hedging (see section 7.5 below).

However, there could be some situations where the cash flow interest rate risk on an asset that is part of a portfolio managed on a fair value basis might be managed outside of the portfolio (or business model), although we expect such a situation to be rare in practice. In these cases, the instrument hedging the interest rate risk is held separately from the managed portfolio. In such a scenario, cash flow hedge accounting is not necessarily inconsistent with the hedged asset being held at fair value through profit or loss. Such a situation is shown in the following Illustration:

Illustration 2-21: Interest rate risk managed separately from a credit risk portfolio managed on a fair value basis

Entity A has excess funds to invest and spreads these across various investment portfolios for which the credit risk is managed by individual portfolio managers on a fair value basis. The individual managers are likely to manage the fair value of the portfolio using credit risk derivatives such as credit default swaps. The entity, however, wishes to retain the management of interest rate risk centrally where it is aggregated with other interest rate exposures across the entity, e.g., from issued debt, and therefore instructs each portfolio manager to invest in order to achieve a 3m benchmark-based rate of return. Accordingly, the majority of assets within each investment portfolio will attract a floating rate and hence most of the portfolio's fair value volatility will arise from changes in credit risk. The interest rate risk is managed centrally and so any interest rate swaps used to fix some of the variability in the future cash flows from changes in interest rate risk are transacted centrally and not part of any investment portfolio, nor are they considered when reporting or assessing the performance of the individual investment portfolios. Each investment portfolio is managed based on its fair value, has discreet fair value financial information and each portfolio manager is assessed on the fair value performance of their portfolio. The entity concludes that the business model test is applied at the portfolio level and as such each investment portfolio is measured at fair value through profit or loss.

It is possible that in these circumstances the decision to enter into interest rate swaps and apply cash flow hedge accounting to an asset within the investment portfolios is not inconsistent with the fact the instrument is held at fair value through profit or loss, since that designation is driven by management of the fair value of credit and not the interest rate element.

2.6.2.B Hedged items held for trading

Derivatives are deemed to be held for trading (see Chapter 44) and are therefore ineligible as hedged items on their own. [IAS 39.F.2.1]. A portfolio that is held for trading is one where assets and liabilities are acquired or incurred principally for the purpose of selling or repurchasing or short-term profit-taking. An entity achieves those objectives by either selling or repurchasing the financial instruments or by entering into an opposite trade to lock-in a gain. In this case hedge accounting of recognised assets and liabilities and highly probable transactions managed within a trading book will not be appropriate for the reasons set out below:

- It is consistent with the prohibition on derivatives being hedged items
 - A trading portfolio is likely to be managed on a fair value basis and so a number of the considerations in section 2.6.2.A above will also apply. Furthermore, it is unlikely that any of the risks within the trading portfolio will be managed other than for trading purposes
- And
- In a trading portfolio where an entity might sell an asset in the near term, the asset will usually not be eligible for cash flow hedging as the future cash flows will not be highly probable

2.6.2.C Hedged items that have failed the contractual cash flows test

Where debt instruments are classified as fair value through profit or loss because they fail the contractual cash flow characteristics test (see Chapter 44), the above arguments do not apply and so it appears that such instruments could be designated as the hedged item in a cash flow hedge, if all other qualifying criteria for hedge accounting are met (see section 6 below).

For other financial instruments subject to the contractual cash flow characteristics test, such as equities, the additional requirement for there to be a systematic way in which the cash flow hedge reserve would be reclassified into profit or loss would seem to preclude cash flow hedge accounting (see section 2.6.2 above).

2.6.3 Hedges of exposures affecting other comprehensive income

Only hedges of exposures that could affect profit or loss qualify for hedge accounting. [IFRS 9.6.5.2]. This would include hedged debt instruments measured at fair value through other comprehensive income (OCI) as although changes in fair value are initially recognised in OCI, on derecognition of such items any gains or losses held in OCI will be reclassified to profit or loss. [IFRS 9.4.1.2A, IFRS 9.B5.7.1A]. However, given the stated business model for debt instruments measured at fair value through OCI includes the possibility of selling financial assets, care would need to be taken to ensure that hedge accounting is not applied to cash flows that are not highly probable (see section 2.6.1 above).

The sole exception to the requirement that hedges could affect profit or loss is when an entity is hedging in a fair value hedge an investment in equity instruments for which it has elected to present changes in fair value in OCI, as permitted by IFRS 9. [IFRS 9.6.5.3]. Using that election, gains or losses on the equity investments will never be recognised in profit or loss (see Chapter 44). [IFRS 9.4.1.4].

For such a hedge, the fair value change of the hedging instrument is recognised in OCI. [IFRS 9.6.5.8]. Any hedge ineffectiveness is also recognised in OCI. [IFRS 9.6.5.3]. On sale of the investment, gains or losses accumulated in OCI are not reclassified to profit or loss, but could be transferred to retained earnings (see Chapter 44). [IFRS 9.B5.7.1]. Consequently, the same also applies for any accumulated fair value changes on the hedging instrument, including any ineffectiveness (see section 7.8 below).

2.6.4 Hedges of a firm commitment to acquire a business

IFRS 9 notes that:

Extract from IFRS 9

B6.3.1 A firm commitment to acquire a business in a business combination cannot be a hedged item, except for foreign currency risk, because the other risks being hedged cannot be specifically identified and measured. Those other risks are general business risks.

[IFRS 9.B6.3.1].

It follows that a forecast business combination could be a hedged item for foreign currency risk in a cash flow hedge, as long as the highly probable criterion is met (see section 2.6.1 above).

The other risks in a future business combination- i.e., other than foreign currency risk, are said to be general business risks. IAS 39 provided additional guidance on hedging general business risks that appears relevant also to IFRS 9. A hedge of the risk of obsolescence of a physical asset or the risk of expropriation of property by a government is not eligible for hedge accounting (effectiveness cannot be measured because those risks are not reliably measurable). [IAS 39.AG110]. Similarly, the risk that a transaction will not occur is an overall business risk that is not eligible as a hedged item. [IAS 39.F.2.8].

Nevertheless, transactions of the business to be acquired (for example floating rate interest payments on its borrowings) could potentially qualify as hedged items. For this to be the case it would need to be demonstrated that, from the perspective of the acquirer, those hedged transactions are highly probable (see section 2.6.1 above) and could impact the post-acquisition profit or loss of the acquirer (see section 5.2 below). Determining that the hedged transaction is highly probable might not be straightforward, as this requirement applies to both the business combination and the hedged transactions themselves.

2.6.5 Forecast acquisition or issuance of foreign currency monetary items

As already mentioned, there is a need for the hedged risk to have the potential to impact profit or loss in order to achieve hedge accounting. [IFRS 9.6.5.2]. Changes in foreign currency rates prior to the acquisition or issuance of a monetary item denominated in a foreign currency do not impact profit or loss as any foreign currency risk on the issue of debt will be offset by the foreign currency risk on the cash that will be spent or borrowed. Therefore, an entity cannot hedge the foreign currency risk associated with the forecast or committed acquisition or issuance of a monetary item denominated in a foreign currency, such as the expected or committed issuance of debt denominated in a currency other than the entity's functional currency.

However, it could be possible to designate a combination of the highly probable forecast acquisition or issuance of a foreign currency monetary item and an associated highly probable forecast foreign currency derivative as an aggregated exposure within a hedge accounting relationship, for the purpose of hedging the associated future interest rate risk (see section 2.7.3.D below).

2.6.6 Own equity instruments

Transactions in an entity's own equity instruments (including distributions to holders of such instruments) are generally recognised directly in equity by the issuer (see Chapter 43) and do not affect profit or loss. Therefore, such instruments cannot be designated as a hedged item (see section 5 below). [IFRS 9.6.5.2]. Similarly, a forecast transaction in an entity's own equity instruments (e.g., a forecast dividend payment) cannot qualify as a hedged item. However, a declared dividend that qualifies for recognition as a financial liability, e.g., because the entity has become legally obliged to make the payment, could qualify as a hedged item. For example, a recognised liability to pay a dividend in a foreign currency would give rise to foreign currency risk.

2.6.7 Core deposits

Financial institutions often receive a significant proportion of their funding from demand deposits, such as current account balances, savings accounts and other accounts that behave in a similar manner. Even though the total balance from all such customer deposits might vary, a financial institution typically determines a level of core deposits that it believes will be maintained for a particular time frame. These customer deposits or accounts usually pay a zero or low, stable interest rate which, while not contractually fixed, is generally insensitive to changes in market interest rates, and hence will behave like a fixed interest rate exposure from an interest rate risk perspective for the time frame over which they are expected to remain.

While these deposits can be withdrawn at little or short notice, typically they are left on deposit for a long time despite the low interest paid. Although the financial institution will not be able to determine which deposits will be withdrawn and which will persist, the overall level of withdrawal could be relatively predictable. Further, both existing and new deposits are generally considered fungible for interest rate risk management purposes, as new deposits will usually be on the same terms as any withdrawn deposits that they replace.

Risk management of the 'deemed' fixed rate interest rate risk exposure that financial institutions attribute to core deposits will often result in the need to transact interest rate derivatives, although achieving hedge accounting for these derivatives can be difficult.⁷

⁷ Discussion Paper [DP/2014/1](#), *Accounting for Dynamic Risk Management: a Portfolio Revaluation Approach to Macro Hedging*, IASB, April 2014, paras. 1.14-1.15 and 3.9.1-3.9.16. Available on the IFRS Foundation's website.

In order for items to be eligible hedged items in a fair value hedge, the fair value of the hedged items must vary with the hedged risk. However, IFRS 13 *Fair Value Measurement* states that the fair value of a financial liability with a demand feature (e.g., a demand deposit) is not less than the amount payable on demand, discounted from the first date that the amount could be required to be paid. [IFRS 13.47]. Therefore, the fair value of demand deposits will not vary with the hedged risk and fair value hedge accounting is precluded.

An alternative consideration is whether it is possible to designate a core deposit intangible asset (representing the value of this source of funding to the financial institution) as an eligible hedged item. The term 'core deposit intangible' could be used to represent the difference between:

(a) The fair value of a portfolio of core deposits

And

(b) The aggregate of the individual fair values of the liabilities within the portfolio, calculated in accordance with the requirements of IFRS 13

Generally, an internally generated core deposit intangible cannot be a hedged item because it is not a recognised asset. However, if a core deposit intangible is acquired together with a related portfolio of deposits, it is required to be recognised separately as an intangible asset (or as part of the related acquired portfolio of deposits) if it meets the recognition criteria in IAS 38 *Intangible Assets*, which it normally will (see Chapter 10).

Theoretically, therefore, a recognised purchased core deposit intangible asset could be designated as a hedged item. However, this will only be the case if it meets the conditions for hedge accounting, including the requirement that the effectiveness of the hedge can be measured reliably. The Implementation Guidance of IAS 39 explains that because it is often difficult to measure reliably the fair value of a core deposit intangible asset other than on initial recognition, it is unlikely that this requirement will be met. [IAS 39.F.2.3]. In fact, this probably understates the difficulty.

For the reasons set out above, financial institutions are rarely, if ever, able to designate core deposits with the associated hedging instruments in hedge accounting relationships, despite the economic validity of these risk management activities. Accordingly, many financial institutions apply the special portfolio or macro hedge accounting guidance in IAS 39 (see section 10 below).

The IASB is however developing a new accounting model for dynamic risk management, focused on interest rate risk management by banks and similar financial institutions. In the development of the new accounting model, the IASB has tentatively decided that core demand deposits will be eligible for inclusion as risk exposures subject to dynamic risk management and hence part of the new accounting solution (see section 10.1 below).

2.6.8 Leases and associated right-of-use assets

IFRS 16 *Leases* requires that at the commencement date, a lessee recognises a right-of-use asset and a lease liability (see Chapter 24). For lessee entities that hedge the foreign currency risk associated with a foreign currency lease liability, hedge accounting may not be required. This is because the foreign currency risk in the hedging instrument will naturally offset part of the IAS 21 retranslation of the lease liability. However, if the foreign currency risk from the lease liability is not economically hedged, the full foreign currency risk arising from future lease payments will be recognised in profit or loss with no hedging instrument providing offset to the IAS 21 retranslation of the lease liability. Accordingly, there could be an incentive either to start economically hedging the foreign currency risk in the lease liability and achieve hedge accounting or natural offset, or to try to achieve hedge accounting using existing foreign currency exposures. In each case, this would be subject to meeting the normal hedge accounting qualifying criteria.

Foreign currency lease liabilities could be either eligible hedged items or hedging instruments (see section 2.1 above and section 3.3.1 below respectively). It might be tempting to consider designating the lease liability as the hedging instrument in a fair value hedge of foreign currency risk in the associated right-of-use asset. A related fact pattern was discussed in June 2019 by the IFRS IC when a number of difficulties were identified.⁸

⁸ [IFRIC Update](#), June 2019, available on the IFRS Foundation's website.

The IFRS IC considered whether foreign currency risk can be a separately identifiable and reliably measurable risk component of a non-financial asset held for consumption that an entity can designate as the hedged item in a fair value hedge accounting relationship. The IFRS IC concluded that, although in theory such a hedge could be possible, the particular facts and circumstances would need to be considered to ensure the hedge accounting criteria were met. The IFRS IC assessed the following key questions as part of their considerations:

Can an entity have exposure to foreign currency risk on a non-financial asset held for consumption that could affect profit or loss? Depending on the particular facts and circumstances, a non-financial asset might be priced-and its fair value determined-only in one currency at a global level and that currency is not the entity's functional currency. The translated fair value of such a non-financial asset would change as a result of changes in the applicable exchange rate in a given period, even if the fair value (determined in the foreign currency) were to remain constant. The Committee therefore observed that in such circumstances an entity is exposed to foreign currency risk. IFRS 9 does not require changes in fair value to be expected to affect profit or loss but, rather, that those changes could affect profit or loss. The IFRS IC observed that changes in fair value of a non-financial asset held for consumption could affect profit or loss if, for example, the entity were to sell the asset before the end of the asset's economic life (see section 5.1 below).

If an entity has exposure to foreign currency risk on a non-financial asset, is it a separately identifiable and reliably measurable risk component? The IFRS IC observed that foreign currency risk is separately identifiable and reliably measurable when the risk being hedged relates to changes in fair value arising from translation into an entity's functional currency of fair value that, based on an assessment within the context of the particular market structure, is determined globally only in one particular currency and that currency is not the entity's functional currency (see section 2.2.5 above).

Can the designation of foreign currency risk on a non-financial asset held for consumption be consistent with an entity's risk management activities? The IFRS IC observed that, in applying IFRS 9, an entity can apply hedge accounting only if it is consistent with the entity's risk management objective and strategy for managing its exposure (see section 6.2.1 below). The Committee noted that it would expect that an entity would manage and hedge exposure to foreign currency risk on the fair value of non-financial assets held for consumption only in very limited circumstances-in such circumstances, an entity would use hedging instruments to hedge only foreign currency risk exposure that it expects will affect profit or loss. This may be the case, for example, if (a) the entity expects to sell the non-financial asset (e.g., an item of property, plant and equipment) part-way through its economic life; (b) the expected residual value of the asset at the date of expected sale is significant; and (c) the entity manages and uses hedging instruments to hedge the foreign currency risk exposure only on the residual value of the asset. Furthermore, the Committee observed that risk management activities that aim only to reduce foreign exchange volatility arising from translating a financial liability denominated in a foreign currency applying IAS 21 are inconsistent with the designation of foreign exchange risk on a non-financial asset as the hedged item in a fair value hedge accounting relationship. In such circumstances, the entity is managing the foreign currency risk exposure arising on the financial liability, rather than managing the risk exposure arising on the non-financial asset. In order to achieve fair value hedge accounting for a foreign currency risk component of a non-financial asset held for consumption, all three questions must be answered satisfactorily. It is unlikely that this will be the case for a fair value hedge of the foreign currency risk in a right-of-use asset, using the associated foreign currency lease liability as the hedging instrument. In most cases, there is not an exposure to foreign currency risk in the right-of-use asset that will affect profit or loss, the fair value of the right-of-use asset is unlikely to be determined globally only in one particular currency and such a hedge is often not consistent with the entity's risk management objective. Even if we consider the case of a right-of-use asset for a wide-bodied aircraft, for which it might be possible to determine that the fair value of the right-of-use asset is determined globally only in US dollars, hedge accounting is still unlikely to be achieved by designating the associated foreign currency lease liability as the hedging instrument if the expectation is that the non-financial asset will be consumed (rather than sold), given the requirement for the designation to be consistent with the entity's risk management objective.

One example of a designation that could potentially meet the criteria for fair value hedge accounting of foreign currency risk in a non-financial asset held for consumption would be the hedge of foreign currency risk by an entity that owned a wide-bodied aircraft, assuming such aircrafts are priced only in one currency at a global level and that currency is not the entity's functional currency (see Chapter 19). The entity owning the wide-bodied aircraft may expect to sell it partway through its economic life for a not insignificant residual value for which the entity manages the foreign currency exposure (perhaps by transacting a foreign currency forward contract). In that case it may be appropriate to conclude that the designation of the foreign currency risk from the residual value of the wide-bodied aircraft is consistent with the entity's risk management objective. Such a scenario is unlikely to be very common and any such designation would need to meet all the usual hedge accounting qualifying criteria (see section 6 below).

2.6.9 Hedge accounting for associates

It is permissible to hedge the foreign currency risk in a firm commitment or highly probable transaction to acquire a business in a business combination (see section 2.6.4 above). [IFRS 9.B6.3.1]. It follows that it is also possible for a firm commitment or a highly probable forecasted acquisition of an equity accounted associate (see Chapter 12) to be the hedged item for foreign currency risk.

Conversely it is not possible for an investor in an associate to identify specific transactions of that associate and apply hedge accounting to those specific transactions in the investor's own financial statements. This is true whether the associate is an existing associate or a highly probable forecast acquisition. Equity accounting for the associate reflects a single interest in the associate rather than a share of the specific transactions; a single transaction of the associate would not meet the separately identifiable and reliably measurable requirement to be an eligible risk component of an interest in an associate (see section 2.2 above and 5.1 below).

2.7 Aggregated exposures

2.7.1 Introduction

IFRS 9 introduced a hedge accounting concept known as 'an aggregated exposure'; the purpose of which was to facilitate hedge accounting that reflects the effect of risk management undertaken for a hedged position that includes a derivative. This will only be the case if the aggregated exposure combines an exposure with a derivative so that it creates a different aggregated exposure that is managed as one exposure for a particular risk. [IFRS 9.B6.3.3]. Further the aggregated exposure must be a combination of an exposure that could qualify as a hedged item, and a derivative together designated as a hedged item. [IFRS 9.6.3.4].

The aggregated exposure is often a hedging relationship itself (the first-level relationship), however, in order for the aggregated exposure to qualify for hedge accounting, IFRS 9 only requires that the exposure could qualify as a hedged item (see section 2.1 above) and not that hedge accounting is actually applied. Applying hedge accounting to the aggregated exposure (the second-level relationship) gets even more complex when hedge accounting is not applied to the first-level relationship, and the entity is also unlikely to achieve its desired accounting result. [IFRS 9.BC6.167]. Therefore, in many cases we expect entities to apply hedge accounting where possible to the first-level relationship, even if it is not required by IFRS 9.

The guidance does not change the unit of account for instruments making up the aggregated exposure, specifically it is not accounted for as a 'synthetic' single item. Instead, an entity is required to consider the combined effect of the aggregated exposure for the purpose of assessing hedge effectiveness and measuring hedge ineffectiveness. [IFRS 9.B6.3.4].

Whilst the ability to designate an aggregated exposure as a hedged item in a hedge relationship is expected to allow an entity to reflect better the effect of its risk management in the financial statements, the steps required to achieve this hedge accounting are quite complex. Furthermore, although some detailed examples of hedge accounting for aggregated exposures are provided in the Illustrative Examples within the Implementation Guidance of IFRS 9, there are still some areas of uncertainty. [IFRS 9.IE115-147]. We outline below the general requirements for hedge accounting for aggregated exposures.

2.7.2 Background

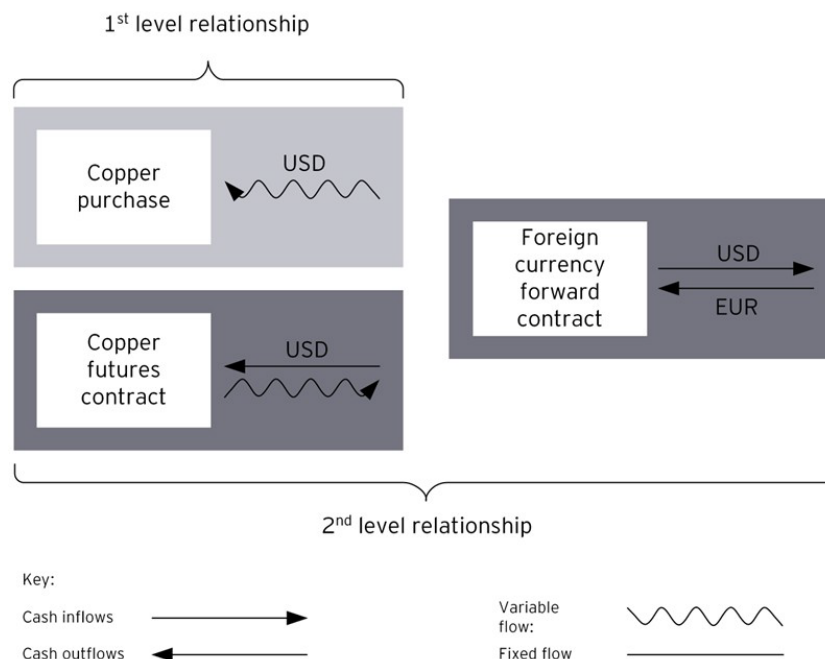

Entities often purchase or sell items (in particular, commodities) that expose them to more than one type of risk (e.g., commodity and foreign currency risk). When hedging those risk exposures, entities do not always hedge each risk for the same time period. This is best explained with an example:

Illustration 2-22: Aggregated exposure - copper purchase in a foreign currency

An entity manufacturing electrical wires is expecting to purchase copper in 12 months. The functional currency of the entity is euro (EUR). The copper price is fluctuating and is denominated in US dollars (USD), which is a foreign currency for the entity. The entity is exposed to two main risks, the copper price risk and the foreign currency risk.

The entity first decides to hedge the copper price fluctuation risk, using a copper futures contract. By doing so, the entity now has a fixed-price copper purchase denominated in a foreign currency and is therefore still exposed to foreign currency risk. (In this example we assume there is no 'basis risk' between the copper price exposures in the expected purchase and the futures contract, such as the effect of quality and the location of delivery).

Three months later, the entity decides to hedge the foreign currency risk by entering into a foreign currency forward contract to buy a fixed amount of USD in nine months. By doing so, the entity is hedging the aggregated exposure, which is the combination of the original exposure to variability of the copper price and the copper futures contract. The diagram below illustrates the two economic hedging relationships.

In the above example it would be possible for the entity to initially designate the copper futures contract as hedging variations in the copper purchase price in a cash flow hedge relationship and leave the foreign currency risk unhedged (see section 2.2.5 above). This is on the assumption that the relevant hedge accounting eligibility criteria are met (see section 6 below). However, when the entity transacts the foreign currency forward contract three months later the general hedge accounting guidance would provide the entity with two choices (see section 8.3 below):

- Discontinue the first hedging relationship (i.e., the copper price risk hedge) and re-designate a new relationship with joint designation of the copper futures contract and the foreign currency forward contract as the hedging instrument. This is likely to lead to some 'accounting' hedge ineffectiveness as the copper futures contract will now have a non-zero (i.e., off market) fair value on designation of the new relationship (see section 7.4.3 below).

Or

- Maintain the copper price risk hedge and designate the foreign currency forward contract in a second relationship as a hedge of the variable USD copper purchase price. Even if the other hedge accounting requirements could be met, this means that the volume of hedged item is constantly changing as it is the variable copper purchase price that is now hedged for foreign currency risk, (i.e., without consideration of the effect of the copper futures). This will likely have an impact on the effectiveness of the hedging relationship, in particular if the variable USD copper price falls, as there might not be sufficient volume of USD cash flows from the designated hedged item in order to match the foreign currency forward contract.

As mentioned above, IFRS 9 includes an additional accounting choice for such a strategy which is to permit designation as hedged items the aggregated exposures that are a combination of an exposure that could qualify as a hedged item and a derivative. [IFRS 9.6.3.4].

Consequently, in the scenario described in Illustration 2-22 above, the entity could designate the foreign currency forward contract in a cash flow hedge of the combination of the original exposure and the copper futures contract (i.e., the aggregated exposure) without affecting the first hedging relationship. In other words, it would not be necessary to discontinue and re-designate the first hedging relationship, as summarised in the table below:

IFRS 9 designations	1st level hedge relationship	2nd level hedge relationship
Hedge relationship	Cash flow hedge	Cash flow hedge
Hedged risk	Copper price	USD/EUR exchange rate
Hedged item	Copper purchases	Combination of copper purchases and copper futures contract
Hedging instrument	Copper futures contracts	Foreign currency forward contract
Designation	Designated when copper futures are transacted. Hedge is not affected by 2 nd level hedge designation	Designated when foreign currency forward contract is transacted

It is important to keep in mind that the individual items in the aggregated exposure are accounted for separately, applying the normal requirements of hedge accounting (i.e., there is no change in the unit of account; the aggregated exposure is not treated as a 'synthetic' single item). For example, when hedging a combination of a variable rate loan and a pay fixed/receive variable interest rate swap (IRS), the loan would still be accounted for at amortised cost with the IRS accounted for at fair value through profit or loss and presented separately in the statement of financial position. An entity would not be allowed to present the IRS and the loan (i.e., the aggregated exposure) together in one line item (i.e., as if it was one single fixed rate loan). [IFRS 9.B6.3.4].

However, when assessing the effectiveness and measuring the ineffectiveness of a hedge of an aggregated exposure, the combined effect of the items in the aggregated exposure must be taken into consideration. [IFRS 9.B6.3.4]. (See sections 6.4 and 7.4 below respectively). This is of particular relevance if the terms of the hedged item and the hedging instrument in the first hedging relationship do not perfectly match, e.g., if there is basis risk. Any ineffectiveness in the first level relationship would automatically also lead to some ineffectiveness in the second level relationship. However, this does not mean that the same ineffectiveness is recognised twice. The accounting for aggregated exposures is explained using a series of examples, below.

2.7.3 Accounting for aggregated exposures

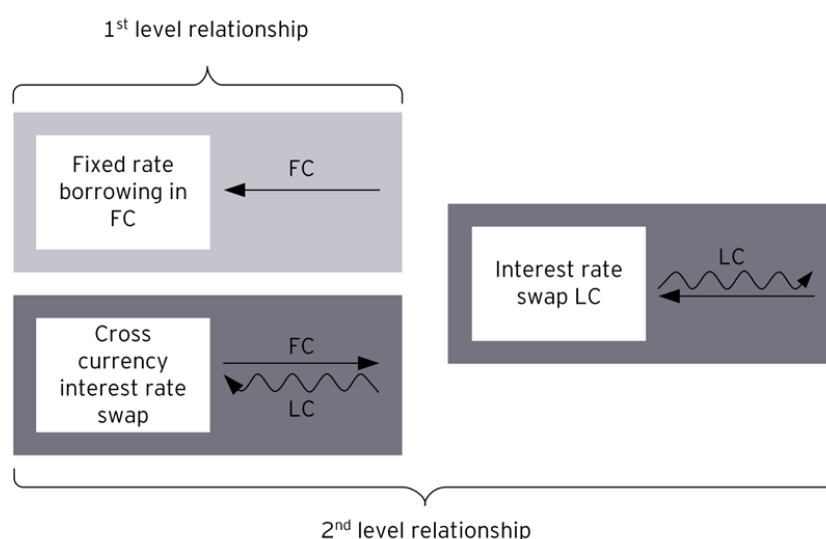

The following examples in the sections below, partly derived from the Illustrative Examples in the Implementation Guidance of IFRS 9, help explain the concept of a hedge of an aggregated exposure. We have not repeated the detailed calculations provided in the Illustrative Examples, but have focused instead on explaining the required approach:

2.7.3.A Cash flow hedge of an aggregated exposure of foreign currency fixed rate loan and cross-currency interest rate swap

Illustration 2-23: Cash flow hedge of interest rate risk of an aggregated exposure made up of a fixed rate loan in a foreign currency and a cross-currency interest rate swap

This fact pattern is based on Example 17 in the Illustrative Examples. [IFRS 9.IE128-137]. An entity has a fixed rate borrowing denominated in a foreign currency (FC) and is therefore exposed to foreign currency risk and fair value risk due to changes in interest rates. The entity decides to swap the borrowing into a functional currency (LC) floating rate borrowing using a cross-currency interest rate swap (CCIRS). The CCIRS is designated as the hedging instrument in a fair value hedge (first-level relationship). By doing so, the entity has eliminated both the foreign currency risk and the fair value risk due to changes in interest rates. However, it is now exposed to variable functional currency interest payments.

Later, the entity decides to fix the amount of functional currency interest payments by entering into an interest rate swap (IRS) to pay fixed and receive floating interest in its functional currency. By doing so, the entity is hedging the aggregated exposure, which is the combination of the original exposure and the CCIRS. The IRS is designated as the hedging instrument in a cash flow hedge (second-level relationship). [IFRS 9.IE131(b)]. The diagram below illustrates the interest flows in the two hedging relationships.

As noted above, the accounting for aggregated exposures can be complex. In this example the complexity lies in the calculation of the present value (PV) of the variability of cash flows of the aggregated exposure. This calculation is necessary in order to calculate the ineffectiveness in the second level relationship, in line with the usual hedge accounting requirements for cash flow hedges. [IFRS 9.6.5.11(a)(ii)].

Example 17 in the Illustrative Examples demonstrates that the variability of the cash flows of the aggregated exposure can be calculated by creating a 'synthetic' aggregated exposure for calculation purposes only. [IFRS 9.IE134(a)]. This is similar to creating what is often referred to as a 'hypothetical derivative' for hedge relationships that do not include aggregated exposures (see section 7.4.4 below).

One leg of the synthetic aggregated exposure is based on the gross cash flows from the aggregated exposure, and the other leg is 'fixed at a blended rate' such that the present value of the whole synthetic aggregated exposure (in local currency) is nil on initial hedge designation. Similar to the role of the fixed leg in a hypothetical derivative, the fixed leg in the synthetic aggregated exposure is designed to reflect the level at which the hedged risk in the aggregated exposure could be locked in on initial designation of the second level relationship. The purpose of this is to capture the present value of the variability of cash flows of the aggregated exposure from that point onwards.

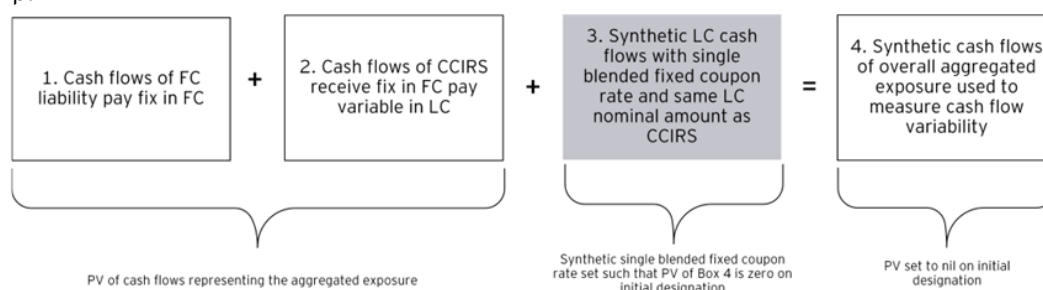

In this particular fact pattern, the leg in the synthetic aggregated exposure that represents the cash flows of the aggregated exposure is a combination of the future foreign currency cash outflows on the liability and the local and foreign currency cash outflows and inflows on the CCIRS. The 'blended' rate for the fixed leg of the synthetic aggregated exposure is calibrated so that the present value of the synthetic aggregated exposure in total is nil on designation of the second level relationship.

In the Illustrative Example, all the cash flows contributing to the leg that represents the cash flows of the aggregated exposure are recorded and valued on a gross basis. It follows that if the cash flows from the foreign currency fixed rate liability and those from the receive fixed foreign currency leg of the CCIRS do not exactly offset, then the resultant foreign currency 'net cash flow' will contribute to the synthetic aggregated exposure leg that represents the cash flows of the aggregated exposure. In this fact pattern where the hedging instrument in the second-level relationship is a local currency IRS without any foreign currency risk, fair value changes associated with such foreign currency net cash flow in the synthetic aggregated exposure would result in ineffectiveness. [IFRS 9.IE134(a)].

When considering the determination of the synthetic aggregated exposure, if a first level relationship has been designated, it is important to consider how the derivative has been included in that first level relationship. The way in which a derivative is included in the aggregated exposure in the second level relationship must be consistent with the designation of that derivative as the hedging instrument in the first level relationship. For example, if an entity excludes the forward element or foreign currency basis spreads from its designation as a hedging instrument in the first level relationship (see section 3.6 below), then it should also exclude it from designation as part of an aggregated exposure in the second level relationship. This has the effect that if the forward element or foreign currency basis spreads are excluded from the first level relationship, those excluded elements are not considered to be fair value drivers of the aggregated exposure within the second level relationship.

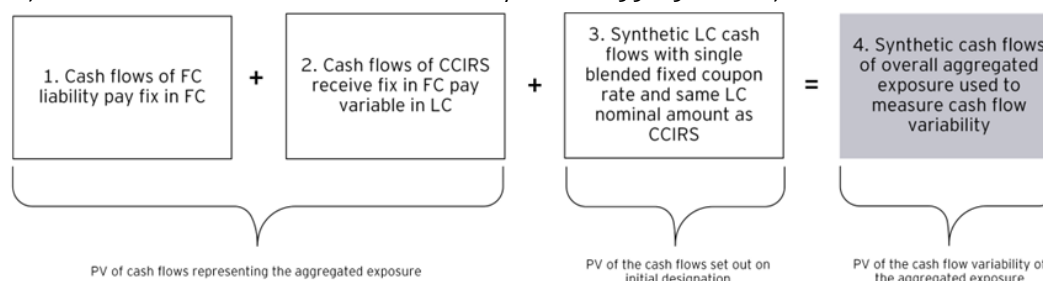

[IFRS 9.B6.3.4(b)].

The diagram below illustrates the methodology described above. The grey field identifies the output from the calculation, which is the calibrated fixed leg of the synthetic aggregated exposure that results in a zero present value for the overall synthetic aggregated exposure on initial designation of the second level relationship.

In each subsequent period, the local currency present values are updated to reflect changes in the cash flows representing the aggregated exposure, associated discount rates (and foreign currency rates if relevant), while holding the previously calibrated blended fixed rate on the synthetic aggregated exposure constant, similar to a hypothetical derivative (see section 7.4.4 below). The sum of the resulting present values of cash flows, i.e., the local currency present value of the overall synthetic aggregated exposure (which previously was calibrated to be nil as at designation), represents the present value of the cash flow variability of the aggregated exposure which is used for measurement of ineffectiveness. [IFRS 9.IE134].

This is illustrated in the diagram below. The grey field represents the output from this calculation which is the current present value of the cash flow variability of the aggregated exposure.

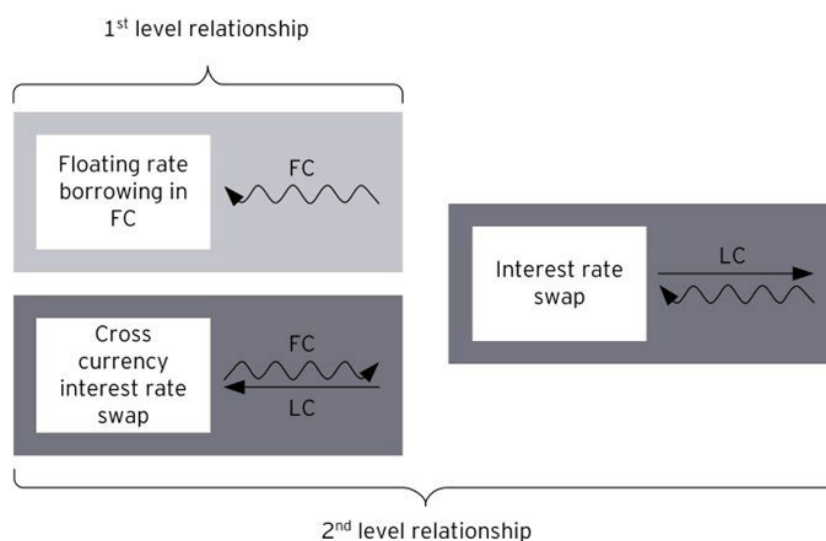

Ineffectiveness is then determined by comparing the change in calculated present value of the cash flow variability of the aggregated exposure and the fair value of the hedging instrument, (i.e., the local currency IRS). The normal ongoing cash flow hedge accounting treatment is applied to the change in fair value of the hedging instrument (see section 7.2 below). The accounting for the first level relationship in Illustration 2-23 above continues unaffected by the second level relationship.

2.7.3.B Fair value hedge of an aggregated exposure of foreign currency floating rate loan and cross-currency swap interest rate swap

Illustration 2-24: Fair value hedge of interest rate risk of an aggregated exposure made up of a floating rate loan in a foreign currency and a cross-currency interest rate swap

This fact pattern is based on Example 18 in the Illustrative Examples. [IFRS 9.IE138-147]. An entity has a floating rate borrowing denominated in a foreign currency (FC) and is therefore exposed to foreign currency risk and cash flow risk due to changes in interest rates. The entity decides to swap the borrowing into a functional currency (LC) fixed rate borrowing using a cross-currency interest rate swap (CCIRS). The CCIRS is designated as the hedging instrument in a cash flow hedge (first-level relationship). By doing so, the entity has eliminated both the foreign currency risk and the cash flow risk due to changes in interest rates. However, it is now exposed to a fair value risk resulting from changes in the functional currency interest rate curve.

Later, the entity decides to hedge this fair value risk and enters into an interest rate swap (IRS) that receives fixed rate and pays floating rate interest in its functional currency. By doing so, the entity is hedging the aggregated exposure, which is the combination of the original exposure and the CCIRS. The IRS is designated as the hedging instrument in a fair value hedge for changes in interest rates (second-level relationship). [IFRS 9.IE139(b)]. The diagram below illustrates the two hedging relationships.

The concept of economically hedging aggregated exposures as such is straightforward. However, the accounting for such relationships includes some complexity, as noted above. As for any hedge accounting relationship, there is a need to calculate the cumulative change in present value of the aggregated exposure in order to measure ineffectiveness in the second level hedge relationship. Paragraph IE144 in the IFRS 9 Illustrative Examples provides some direction as to how this will be achieved: similar to Illustration 2-23 above, this can be calculated as the change in local currency present value of the gross cash flows from the instruments making up the aggregated exposures. However, in this example there is no requirement to create a synthetic blended fixed leg, as the aggregated exposure itself is essentially fixed.

An additional complexity in Illustration 2-24 above, is that it is a cash flow hedge in the first-level relationship that is then designated as the hedged item in a fair value hedge. The cross-currency interest rate swap is both a hedging instrument (first level cash flow hedge relationship) and part of a hedged item (second level fair value relationship) at the same time. Accordingly, its fair value changes are initially recognised in other comprehensive income (OCI) through the first level cash flow hedge accounting, but at the same time, will also offset the fair value changes in profit or loss of the hedging IRS in the second-level fair value relationship. This requires a reclassification of the amounts recognised in OCI to profit or loss (to the extent they relate to the second-level relationship) to achieve the offset in the second-level fair value hedge relationship. Consequently, applying fair value hedge accounting to a cross-currency interest rate swap designated as the hedged item as part of an aggregated exposure affects where the hedging gains or losses from the first level cash flow hedge relationship are recognised (i.e., reclassification from the cash flow hedge reserve to profit or loss). [IFRS 9.IE143].

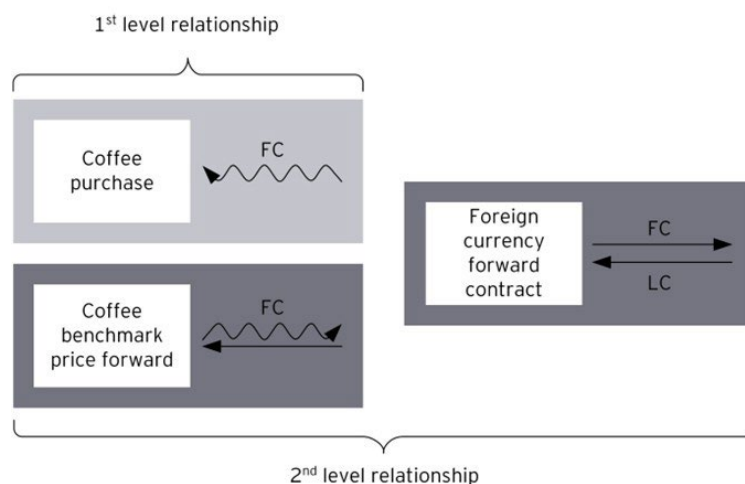

2.7.3.C Cash flow hedge of an aggregated exposure of coffee purchases and benchmark price coffee forward contract

As explained in the Illustrative Examples, the application of hedge accounting to an aggregated exposure gets even more complicated when basis risk is involved in one of the hedging relationships, in particular if basis risk is present in the first-level relationship. This is shown in Illustration 2-25 below.

Illustration 2-25: Cash flow hedge of foreign currency risk of an aggregated exposure made up of forecast commodity purchases and a commodity forward contract

This fact pattern is based on Example 16 in the Illustrative Examples [IFRS 9.IE116-127]. Entity A, with functional currency (LC), enters into a coffee benchmark price forward contract to hedge its highly probable coffee purchases in foreign currency (FC) in five years. The coffee price that Entity A expects to pay for its coffee purchases is different from the benchmark price. This differential could be because of differences in one or a combination of factors such as the type of coffee, the location or delivery arrangements. Entity A designates the benchmark price forward contract and the highly probably forecast transaction as a cash flow hedge (the first level relationship). The entity designates the entire price risk and not only the benchmark price risk as it was not able to separately identify a benchmark price component in the hedged item (see section 2.2.3 above). Accordingly, basis risk exists in the first level relationship. The entity is still exposed to foreign currency risk.

One year later, the entity hedges the foreign currency risk by entering into a foreign currency forward contract. The entity designates the aggregated exposure in the first level relationship and the foreign currency forward contract as a cash flow hedge (the second level relationship). [IFRS 9.IE119(b)]. The diagram below illustrates the two hedging relationships.

Example 16 in the Illustrative Examples of IFRS 9 demonstrates the accounting effort required in order to achieve hedge accounting for the aggregated exposure. First, the entity calculates the change in fair value of the hedged item and hedging instrument in the first level cash flow hedge relationship in foreign currency and translates them into local currency, using spot rates. Using these local currency equivalents, the entity calculates the ineffectiveness in the first level hedging relationship in the usual way. Second, the entity calculates the change in fair value of the aggregated exposure and the hedging instrument in the second-level cash flow hedge relationship in local currency. This results in the second level ineffectiveness.

The existence of basis risk within the first level relationship complicates the measurement of ineffectiveness in the second level relationship described above. The aggregated exposure is a combination of the foreign currency cash flows expected from the highly probable coffee purchases (i.e., the hedged coffee purchase volume multiplied by the current forward price) and the undiscounted gain or loss on the commodity hedging contract (i.e., the expected price differential from benchmark coffee price movements in FC that Entity A will receive or pay under the commodity forward contract). If the first level relationship was a 'perfect hedge', the resultant foreign currency cash flow to be hedged in the second level relationship would be known. However, as commodity basis risk exists in the first level relationship, the hedged amount of foreign currency in the second level relationship will vary, as the basis spread between the price of the forecast coffee purchases and the underlying coffee price in the hedging contract varies. The hedging instrument in the second level relationship is just a foreign currency forward contract, and so its fair value changes are insensitive to commodity basis risk. Accordingly, additional ineffectiveness could arise in the second level relationship, due to the commodity basis risk that exists in the first level relationship.

[IFRS 9.IE122, IFRS 9.IE119(b)].

For example, at inception of the second level relationship, an entity might have expected a hedged aggregated cash flow of FC990 based on the price achieved in the commodity hedging contract and the level of basis risk that then existed. The expected aggregated hedged foreign currency cash flow at inception is calculated as follows:

Designated volume of hedged coffee purchases ×
prevailing forward coffee price for actual coffee purchases

Plus

Designated volume of the hedging instrument multiplied by the difference between the contractual forward coffee price and the current forward coffee price referenced in the forward contract.

However, at the date when the entity calculates the ineffectiveness, the expected aggregated cash flow from the forecast coffee purchase and the commodity hedging contract might be FC1,000 due to changes in the commodity basis risk in the first level relationship. In that case an entity would need to measure effectiveness as if the current expected hedged cash flow from the aggregated exposure was always the expectation at inception (i.e., FC1,000 in the example given above). [IFRS 9.IE122, IFRS 9.IE123].

Specifically, for the second level relationship in this scenario the effective portion taken to OCI would be calculated as the lower of the following amounts: [IFRS 9.6.5.11(a)]

Change in fair value of the current expected hedged
cash flow from the aggregated exposure as if they had existed since inception.
(e.g., based on a hedged cash flow of FC1,000)

And

Change in fair value of the actual hedging instrument.
(e.g., based on original assumption of hedged flow of FC990)

As is usual for cash flow hedges (see section 7.2 below), ineffectiveness to be reported in the profit or loss is the change in fair value of the actual hedging instrument less the effective portion taken to OCI.

Hence it can be seen that for hedge effectiveness measurement purposes, not only is the change in fair value of the hedged cash flows affected by variations in the second level relationship hedged risk, but also by ineffectiveness in the first level relationship. This second driver of fair value change can be seen in the example above as, although the hedging instrument has a notional of FC990, the hedged cash flow is updated to FC1,000, to reflect ineffectiveness in the first level relationship. This is likely to result in incremental ineffectiveness in the second level relationship.

Example 16 in the Illustrative Examples demonstrates that to reduce the basis risk the entity could choose a hedge ratio other than 1:1 for the first level relationship (see section 6.4.3 below). In the example, the entity selects the volume of foreign currency forward contract for the hedging instrument in the second level relationship based on the implied coffee forward price at the time the first level relationship was designated. This assumes the entity's original long-term expectations of the basis spread have not changed since the coffee forward was transacted, which might not always be the case. Alternatively, when identifying the optimal volume of the hedging instrument, an entity could conclude that the appropriate basis spread is the prevailing basis spread at the time of designation of the second level relationship. However, of course, the actual basis spread the entity will suffer is unknown.

Another layer of complexity would be added if the entity subsequently needed to rebalance the hedge relationship because of changes in the expected basis. The example, however, does not include this. Although the accounting for the second level relationship could be complex, the accounting for the first level hedge relationship in this example would continue to be unaffected by the existence of the second level relationship.

2.7.3.D Cash flow hedge of an aggregated exposure of forecast foreign currency debt and forecast cross-currency swap interest rate swap

The definition of an aggregated exposure also includes a forecast transaction of an aggregated exposure (i.e., uncommitted but anticipated future transaction that would give rise to an exposure and a derivative) if that aggregated exposure is highly probable. [IFRS 9.6.3.4]. An example, where this might be helpful, is when pre-hedging the interest rate risk in a forecast foreign currency debt issue:

Illustration 2-26: Cash flow hedge of interest rate risk of an aggregated exposure made up of forecast foreign currency debt and forecast cross-currency swap interest rate swap

Assume it is highly probable that an entity will issue foreign currency debt in six months' time. It is also highly probable that on issue the entity will transact a CCIRS, converting the debt to functional currency variable rate debt. The combination of the forecast foreign currency debt issuance and the forecast transaction of the CCIRS is economically a forecast functional currency variable rate debt issuance.

The entity wishes to hedge itself against increases in the variable functional currency interest rate between today and the issue of the debt in six months as well as over the term of the debt. Therefore, the entity enters into a forward starting pay fixed/receive variable functional currency IRS. The entity designates the IRS as a hedging instrument in a cash flow hedge of the forecast aggregated exposure.

In this example, the first level relationship does not exist yet, as both the hedged item (foreign currency debt) and the hedging instrument (CCIRS) are forecast transactions. Hedge accounting for the 'second level hedge relationship' of the forecast aggregated exposure is still permitted though, on the condition that when the aggregated exposure occurs and is no longer forecast, it would be eligible as a hedged item. [IFRS 9.6.3.4].

As noted above, only forecast aggregated exposures that are highly probable of occurring are eligible as hedged items in a second level hedge relationship (see section 2.6.1 above). Although all the terms of the highly probable forecasted aggregated exposure may not be known definitively in advance, it is important that they are known with reasonable specificity, both in order to measure any ineffectiveness from the hedge relationship (see section 7.4 below) and also to determine whether and when the documented hedged item occurs (see section 8.3 below). In particular, when measuring ineffectiveness, all key terms of the aggregated exposures that are relevant to the measurement of ineffectiveness must be determinable. It is less important that any features excluded from the hedge relationship are known. For example, in the scenario described in Illustration 2-26 above, if the foreign currency basis spreads of the forecast CCIRS will be excluded from the future hedge relationship in which the CCIRS is the hedging instrument and the foreign currency debt is the hedged item, foreign currency basis spreads are not a key term relevant for measurement of ineffectiveness in the hedge relationship of the forecast aggregated exposure (see section 2.7.3.A above). Documentation of the second level relationship should include the expectation that certain elements (e.g., foreign currency basis spreads) will be excluded in the first level relationship. [IFRS 9.B6.3.4(b)].

2.7.3.E Cash flow hedge of an aggregated exposure of a net investment in a foreign operation and cross-currency swap interest rate swap

Just because an entity enters into an additional derivative transaction that relates to an existing hedging relationship it does not mean that this relationship qualifies as an aggregated exposure. This is demonstrated by the following Illustration.

Illustration 2-27: Cash flow hedging of an aggregated exposure that includes a net investment in a foreign operation and a cross currency interest rate swap

Parent A with functional currency Australian dollars (AUD) has a US dollar (USD) net investment exposure. It transacts a pay floating USD receive floating AUD cross-currency interest rate swap (CCIRS) and designates it in a hedge of a net investment in a foreign operation (see section 5.3 below). By doing so, the group is exposed to cash flow variability due to the floating rate exposure in AUD and USD. Parent A also enters into a pay floating/receive fixed AUD interest rate swap (IRS) to eliminate cash flow variability from changes in AUD interest rate risk, and wishes to designate this derivative as the hedging instrument item in a cash flow hedge for the aggregated exposure including the net investment in a foreign operation.

While there is an economic relationship between the net investment exposure and the CCIRS for foreign currency risk, there is no economic relationship between the aggregated exposure and the IRS for interest rate risk. This is because the USD floating interest rate cash flows on the CCIRS are not offset by the USD net investment, as it does not have cash flow variability that is closely linked to interest rates. Furthermore, aggregated exposures can only be designated if they are managed as one exposure for a particular risk, which is unlikely to be the case in this fact pattern given the lack of interest risk associated with the net investment. [IFRS 9.B6.3.3].

3 Hedging instruments

3.1 General requirements

The basic requirement for a hedging instrument is for it to be one of the following (or a proportion thereof (see section 3.6 below)):

- A derivative measured at fair value through profit or loss, except for some written options (see section 3.2 below)
 - A non-derivative financial asset or liability measured at fair value through profit or loss (see section 3.3 below)
- Or
- For a hedge of foreign currency risk, the foreign currency risk component of a non-derivative financial asset or liability (see section 3.3.1 below) [IFRS 9.6.2.1, IFRS 9.6.2.2]

Hedging instruments must also involve a party that is external to the reporting group. [IFRS 9.6.2.3]. Two or more financial instruments can be jointly designated as hedging instruments (see section 3.5 below). [IFRS 9.6.2.5].

There is no requirement to designate a hedging instrument only on initial recognition. Designation of a hedging instrument sometime after its initial recognition (e.g., after a previous hedge relationship is discontinued) is permitted, although some additional ineffectiveness could arise (see sections 2.4.1 above and 7.4.3 below). [IFRS 9.B6.5.28].

3.2 Derivatives as hedging instruments

The distinction between derivative and non-derivative financial instruments is covered in Chapter 42. The standard does not restrict the circumstances in which a derivative measured at fair value through profit or loss can be designated as a hedging instrument, except for some written options. A written option does not qualify as a hedging instrument, unless the written option is designated to offset a purchased option. Purchased options include those that are embedded in another financial instrument and not required to be accounted for separately (see Chapter 42). [IFRS 9.B6.2.4].

How we see it

Although not specifically mentioned in the standard, we believe that embedded purchased options in non-financial instruments that are not required to be bifurcated could also be designated as being hedged by a written option.

A single instrument combining a written option and a purchased option, such as an interest rate collar, cannot be a hedging instrument if it is a net written option at the date of the designation. Similarly, options that are transacted as legally separate contracts could be jointly designated as hedging instruments if the combined instrument is not a net written option at the date of designation. [IFRS 9.6.2.6]. There appears to be no requirement for the jointly designated options to be with the same counterparty. See section 3.2.2 below for further discussion as to what constitutes a net written option.

A contract that is considered a normal sale or purchase, and is therefore accounted for as an executory contract (see Chapter 41), cannot be an eligible hedging instrument as it is not measured at fair value through profit or loss. However, IFRS 9 does provide an alternative to hedge accounting for normal sale or purchase contracts in that a fair value option designation may be possible at inception of the contract (see section 11.2 below).

In addition, a forecast transaction or planned future transaction cannot be the hedging instrument as it is not a recognised financial instrument, and is therefore not a derivative. [IFRS 9.B3.1.2(e)].

3.2.1 Offsetting external derivatives

Where two offsetting derivatives are transacted at the same time, it is generally not permitted to designate one of them as a hedging instrument in a hedge when the derivatives are viewed as one unit of account.

[IFRS 9.6.2.4]. Indicators that the two derivatives must be accounted for as one unit are as follows:

- The second derivative was entered into at the same time and in contemplation of the first
 - There is a no apparent economic need or substantive business purpose for structuring the transactions separately, that could not also have been accomplished in a single transaction
 - They relate to the same risk
- And
- The derivatives are with the same counterparty [IFRS 9.IG B.6]

This issue is also discussed in Chapter 42. It is emphasised that judgement must be applied in determining what a substantive business purpose is. For example, a centralised treasury entity could enter into third party derivative contracts on behalf of other subsidiaries to hedge their interest rate exposures and, to track those exposures within the group, enter into internal derivative transactions with those subsidiaries. It could also enter into a derivative contract with the same counterparty during the same business day with substantially the same terms as a contract entered into as a hedging instrument on behalf of another subsidiary as part of its trading operations, or because it wishes to rebalance its overall portfolio risk. In this case, there is a valid business purpose for entering into each contract. However, a desire to achieve hedge accounting for the hedged item is deemed not to be a substantive business purpose. [IAS 39.F.1.14]. This issue can also arise when derivatives transacted between the retail banking and investment banking legal entities within a banking group are novated to a central clearing party (see section 4.1.1 below).

The assessment as to whether such a substantive business purpose exists or not must be made based on the particular facts and circumstances, including consideration of the regulatory environment, and the judgement documented accordingly.

3.2.2 Net written options

It was explained in IAS 39 that an option an entity writes is not effective in reducing the profit or loss exposure of a hedged item. In other words, the potential loss on a written option could be significantly greater than the potential gain in value of a related hedged item. [IAS 39.AG94, IFRS 9.BC6.151]. This is the rationale for prohibiting a written option from qualifying as a hedging instrument unless it is designated as an offset to a purchased option, including one that is embedded in another financial instrument and not required to be accounted for separately (see Chapter 42). An example of this might be a written call option that is used to hedge a callable liability. [IFRS 9.B6.2.4]. In contrast, a purchased option has potential gains equal to or greater than potential losses on a related hedged item and therefore has the potential to reduce profit or loss exposure from changes in fair values or cash flows. Accordingly, a purchased option can qualify as a hedging instrument. [IAS 39.AG94].

It follows that a derivative such as an interest rate or foreign currency collar that includes a written option cannot be designated as a hedging instrument if the collar is a net written option.

Accordingly, determining whether an option contract or a combination of options (see section 3.5 below) constitutes a net written option is an important step in hedge designation, and can require judgement. The following factors, taken together, indicate that an instrument or combination of instruments is not a net written option:

- No net premium is received, either at inception or over the life of the combination of options - the distinguishing feature of a written option is the receipt of a premium to compensate for the risk incurred.
 - Except for the strike prices, the critical terms and conditions of the written and purchased option components are the same, including underlying variable(s), currency denomination and maturity date.
- And
- The notional amount of the written option component is not greater than that of the purchased option component. [IFRS 9.BC6.153].

The application of these requirements is better demonstrated in the following Illustrations.

Illustration 3-1: Hedging foreign currency risk of a forecast transaction using a combined option instrument

An entity is exposed to foreign currency risk resulting from a highly probable forecast transaction in a foreign currency. In order to hedge that exposure, the entity enters into a collar by combining a long call and a short put option. The premium paid on the long call option equals the premium received on the short put option (i.e., it is what is termed a 'zero cost collar').

The entity wishes to designate the combination of the two instruments in a cash flow hedge of its highly probable forecast transaction with respect to changes in foreign currency risk within the specified hedged range (see section 2.1 above). However, applying the requirements above, in order to determine whether the collar is a not a net written option, additional information would be required as consideration of premium on its own is insufficient.

Illustration 3-2: Foreign currency collar (or 'cylinder option')

Company E, which has sterling as its functional currency, has forecast that it is highly probable it will receive €1,000 in six months' time in respect of an expected sale to a customer in France.

E is concerned that sterling might have appreciated by the time the payment is received and wishes to protect the profit margin on the sale without paying the premium that would be required with an ordinary currency option. E also wishes to benefit from some of the upside in the event that sterling depreciates, so would prefer not to use a forward contract.

Accordingly, E enters into an instrument under which it effectively:

- Purchases an option that allows it to buy sterling for €1,000 from the counterparty at €1.53:£1.00
And
- Sells an option that allows the counterparty to sell sterling to E for €1,000 at €1.47:£1.00

If, in six months' time, the spot exchange rate exceeds €1.53:£1.00, E will exercise its option to sell €1,000 at €1.53:£1.00, effectively fixing its minimum proceeds on the sale (in sterling terms) at £654. Similarly, if the rate is below €1.47:£1.00, the counterparty will exercise its option to buy €1,000 at €1.47:£1.00, effectively capping E's maximum proceeds on the sale at £680. If the rate is between €1.47:£1.00 and €1.53:£1.00, both options will lapse unexercised and E will be able to sell its €1,000 for sterling at the spot rate, generating between £654 and £680. So, the option only provides protection against changes in the €/£ spot exchange rate above €1.53 and below €1.47, the hedged range (see section 2.1 above).

The premium that E would pay to acquire the purchased option equals the premium it would receive to sell the written option and therefore no premium is paid or received on inception. The critical terms and conditions, including the notional amounts, of the written and purchased option components are the same except for the strike price. Therefore, E concludes that the instrument is not a net written option and, consequently, it could be used as the hedging instrument in a hedge of the foreign currency risk associated with the future sale.

It is possible that the counterparty might, instead, have offered E a variation on the instrument described above. If the notional amount on E's purchased option component had been reduced, say to €500, the counterparty could have offered a better rate on that component, say €1.51. However, in this case, the notional amount on the written option component would have been twice that of the purchased option component and the instrument would have been seen as a net written option. Accordingly, even if E had very good business reasons for using such an instrument to manage its foreign currency risk, it could not qualify as a hedging instrument. Therefore, hedge accounting would be precluded.

Illustration 3-3: 'Knock-out' swap

Company Y has a significant amount of long-dated floating rate borrowings. In order to hedge the cash flow interest rate risk arising from these borrowings, Y has entered into a number of matching pay-fixed, receive-floating interest rate swaps that effectively convert the interest rates on the borrowings to fixed-rate.

Under the terms of one of these swaps, on each fifth anniversary of its inception until maturity, the swap counterparty might choose to simply terminate the swap at no cost if the relevant floating rate on the interest rate swap exceeded 6%. This is often referred to as a knock-out feature. In return for agreeing to this, Y benefits by paying a lower interest rate on the fixed leg of the swap than it would on a conventional swap. In other words, Y receives a premium for taking on the risk of the counterparty cancelling the swap.

This instrument contains a net written option, i.e., the knock-out feature, and therefore cannot be used as a hedging instrument unless it is used in a hedge of an equivalent purchased option. (In practice, it is unlikely that the hedged borrowings will contain such an option feature).

Illustration 3-4: Zero cost interest rate collar

Company T has 3-year floating rate debt, paying monthly coupons based on a benchmark rate. Company T wants to protect against rises in the benchmark rate but also wishes to benefit to some extent from any reduction in that rate. In line within this risk management objective, Company T transacts a zero cost collar contract (i.e., no premium is paid or received). The terms of the collar are such that for each monthly fixing the benchmark rate is capped at 1.5% and floored at 1%. Accordingly, the contract is in fact a series of 36 purchased European collars with one collar expiring every month for the next 36 months. The critical terms such as notional, benchmark rate and fixing dates of the zero cost collar matches those of the hedged floating rate debt. The zero cost collar is designated as hedging variability in the benchmark rate with respect to the floating rate debt within the collar hedged range (i.e., benchmark rate < 1% or >1.5%). The zero cost collar is not a net written option. This is despite the fact it might very well be that if the zero cost collar were to be deconstructed into 36 single collars, for one or more individual months there might be a net premium receivable. This approach is consistent with the documentation of the collar as a single financial instrument, with a single 'overall' price, and a single hedge designation.

When hedging with a combination of options, assessing whether the combination is a net written option can be an essential step in order to achieve hedge accounting. This assessment must be undertaken on the date of the hedge designation. For example, if a combination is designated sometime after the combination was transacted, it is insufficient to conclude that the combination did not result in receipt of a premium as at the combination transaction date. Consideration must be given to the relative risks associated with the options within the combination on the date of designation. If the fair value of the combination is negative on designation date, then that is usually an indication that the instrument is considered a net written option at that time, and is therefore ineligible for hedge accounting.

See sections 3.6.4, 7.4.11 and 7.5.1 below for further discussion of the implications of using options as hedging instruments.

3.2.3 Embedded derivatives

Only derivatives that are measured at fair value through profit or loss are eligible hedging instruments. [IFRS 9.6.2.1]. Derivatives that are embedded in hybrid contracts, but that are not separately accounted for, cannot be designated as separate hedging instruments. [IFRS 9.B6.2.1]. Given that embedded derivatives in financial assets are not accounted for separately under IFRS 9 (see Chapter 44), this guidance precludes designation of embedded derivatives in financial assets as separate hedging instruments. [IFRS 9.BC6.119].

However, an embedded derivative that is accounted for separately from its host contract (either a financial liability or non-financial host) (see Chapter 42), is measured at fair value through profit or loss, and therefore could be an eligible hedging instrument.

Illustration 3-5: Hedging with a sales commitment

Company J has the Japanese yen as its functional currency. J has issued a fixed-rate debt instrument with semi-annual interest payments that matures in two years with principal due at maturity of US\$5 million. It has also entered into a fixed price sales commitment for US\$5 million that matures in two years and is not accounted for as a derivative because it qualifies for the normal sales exemption.

Because the sales commitment is accounted for as a firm commitment (i.e., it is not recognised until at least one of the parties to the contract has performed (see Chapter 45)) rather than a derivative instrument, it cannot be a hedging instrument in a hedge of the foreign currency risk associated with the debt instrument. However, if the foreign currency component of the sales commitment was required to be separated as an embedded derivative (essentially a forward contract to buy US dollars for yen) (see Chapter 42) that component could be designated as the hedging instrument in such a hedge. [IAS 39.F.1.2].

3.2.4 Credit break clauses

It is not uncommon for certain derivatives (e.g., long-term interest rate swaps) to contain terms that allow the counterparties to settle the instrument at a so-called 'fair value' in certain circumstances. The 'fair value' is usually not a true fair value as it excludes changes in credit risk. Such terms, often called 'credit break clauses', enable the counterparties to manage their credit risk in markets where collateral or margin accounts and master netting agreements are not used. They are particularly common where a long-duration derivative is transacted between a financial and non-financial institution. For example, the terms of a twenty-year interest rate swap could allow either party to settle the instrument at fair value on the fifth, tenth and fifteenth anniversary of its inception.

These terms can be seen as options on counterparty credit risk. However, provided the two parties have equivalent rights to settle the instrument at 'fair value', the credit break clause will generally not prevent the derivative from qualifying as a hedging instrument.

3.2.4.A Principal resetting cross-currency swaps

Another mechanism aimed at reducing ongoing credit risk in longer term derivatives is a principal resetting feature, typically within floating-floating cross-currency swaps. The principal resetting feature allows the fair value of the swap to be settled on a quarterly basis without terminating the swap itself.

Similar to a standard cross-currency swap, the fair value of a principal resetting floating-floating cross-currency swap changes in response to the movements in foreign currency rates; however, the principal resetting feature means that the fair value of the swap attributable to foreign currency spot movement is cash settled at each quarterly reset date, in addition to the normal interest settlements.

Depending on changes in foreign currency spot rates, this could result in either a cash inflow (for the positive fair value) or outflow (for the negative fair value) at the end of each quarter. The notional of the principal resetting swap is then reset to the prevailing foreign currency spot rate.

The resetting feature itself does not appear to preclude the swap from being an eligible hedging instrument (see section 3.2 above), however the implications of using such a swap as the hedging instrument in a hedge relationship need further consideration. This is best achieved by way of an example.

Illustration 3-6: Hedging with a principal resetting cross-currency swap

Company A has the Australian dollar as its functional currency. Company A has issued USD variable rate debt with principal due at maturity of USD100 million. Company A wishes to eliminate the foreign currency risk associated with the foreign currency debt and enters into a principal resetting cross-currency swap; the current terms of which are to receive a specified variable benchmark rate of interest on USD100m and pay a specified variable benchmark rate of interest plus a cross-currency spread on AUD148m. Interest coupons are settled (and reset) on a quarterly basis.

The principal reset feature requires that the fair value of the swap attributable to the foreign currency spot movement is cash settled at each quarterly reset date, and the principal of the receive USD leg is adjusted to reflect the prevailing spot rate.

If the foreign currency spot rate had changed such that on the first quarterly reset date it was AUD1.4:USD1, Company A would pay USD5.7m, and the USD principal would be adjusted to USD105.7m to reflect the prevailing foreign currency spot rate ($\text{AUD148m} \div 1.4 = \text{USD105.7m}$).

Company A could wish to designate the USD debt as the hedged item and the principal resetting swap as the hedging instrument, however, in order to achieve hedge accounting all the hedge accounting criteria must be met (see section 6 below). In this case, the impact of the variation in the swap principal could be problematic, in particular where, as in this example, it is the foreign currency leg of the swap that is reset, as this will most likely require some amendment to the hedge relationship. For example, after the first quarterly reset rate the pay USD leg of the principal reset swap is now USD105.7m, however the hedged item remains the USD100m variable rate debt.

Company A will need to consider how best to adjust the hedge relationship to reflect the ongoing risk management strategy and continue to meet the hedge accounting criteria (see section 8 below).

3.2.5 Basis swaps

A derivative which does not reduce risk at the transaction level cannot be a hedging instrument. Consider a 'basis swap' that effectively converts one variable interest rate index (say a central bank base rate) on a liability to another (say SONIA). A relationship of this nature would not normally qualify for hedge accounting because the hedging instrument does not reduce or eliminate risk in any meaningful way - it simply converts one risk to another similar risk.⁹ For this reason, such an economic strategy would not qualify as either a fair value or cash flow hedge relationship (see sections 5.1 and 5.2 below).

⁹ [IASB Staff Paper 4B](#), Project: *Dynamic Risk Management*, Paper topic: *Derivatives used for DRM purposes*, IASB Meeting, June 2018, para. 11. Available on the IFRS Foundation's website.

A basis swap or similar instrument could qualify as a hedging instrument when considered in combination with another instrument (see section 3.5 below). For example, the basis swap described above and a pay-fixed, receive-SONIA interest rate swap could qualify as a hedging instrument in a cash flow hedge of a borrowing that pays interest based on a central bank rate. It could also be notionally decomposed and designated in hedges of offsetting gross asset and liability positions (see Illustration 3-13 in section 3.6.2 below).

However, a currency basis swap that converts foreign currency variable rate interest and principal cash flows from a financial instrument into variable rate interest and principal cash flows in functional currency could be eligible as a hedging instrument in a cash flow hedge, as variability in cash flows with respect to foreign currency has been reduced (or eliminated). The fact that variability in cash flows with respect to interest rate risk remains, does not preclude hedge accounting for foreign currency risk (see section 2.2.5 above and Illustration 3-12 in section 3.6.2 below).

3.2.6 Power Purchase Agreements

It is becoming increasingly common for entities to enter into long term contracts for renewable energy, often referred to as power purchase agreements. These could be either physical power purchase agreements (PPAs) or virtual power purchase agreements (VPPAs).

VPPAs do not involve the physical purchase or delivery of energy but are typically structured as a 'contract for difference' between the fixed price (per MW of energy) determined in the VPPA and the spot price at which energy could be purchased from the grid (i.e., net settled). The volume of energy determined in such contracts is usually based on all or a proportion of the energy produced from a referenced production facility, hence the volume is variable and cannot be determined with certainty in advance.

These contracts would typically meet the definition of a derivative (see Chapter 42) and are often transacted as part of a risk management strategy for the physical purchase of energy used in a business. Therefore, a common question arises as to whether it is possible to achieve hedge accounting with VPPAs as the hedging instrument. A similar question arises for the purchaser in physical power arrangements (PPAs) which do not meet the 'own use' requirements and are also accounted for as derivatives (see Chapter 41). As VPPAs and PPAs that do not meet the own use requirements are derivatives, they are eligible hedging instruments (see section 3.2 above), however there are still some challenges in achieving hedge accounting.

The main challenges in achieving hedge accounting for VPPAs and PPAs arise from the fact that, unlike most other contracts where cash flow variability only arises because of price uncertainty, in such contracts for renewable electricity, cash flow variability arises because of both price and volume uncertainty. This is due to the underlying volume of energy in the contract typically being based on a proportion of the energy produced from a referenced production facility.

In March 2019 the IFRS IC observed that forecast sales cannot be specified as a hedged item solely as a percentage of sales during a period because that would lack the required specificity in terms of magnitude and timing (see sections 2.3.1 and 2.6.1 above and section 6.3.3 below). It follows that, for all hedge designations, a known amount or component of hedged item must be identified. This precludes designating as the hedged item a proportion of the volume of energy produced by a referenced production facility.

When designating in a cash flow hedge a hedging instrument that is a VPPA or PPA for which the volume of energy is dependent on production, the need to designate a known volume of energy as the hedged item does not preclude hedge accounting, but it does create challenges.

In the case of a supplier of renewable energy, in order to achieve hedge accounting for forecast sales of energy, a known volume of energy must be designated. This is even though the VPPA is economically hedging a variable volume of energy equal to a proportion of the total energy produced.

Similarly, in the case of a purchaser, a known volume of energy purchased must be designated in order to achieve hedge accounting. This is the case even if the purchaser had determined that it is highly probable its energy needs will exceed the expected volume of renewable electricity from the production facility as referenced in the VPPA or PPA.

It may be difficult to determine that an economic relationship exists between a hedged item based on a fixed volume of energy and a hedging instrument based on a variable volume (see section 6.4.1 below). Factors to consider within this assessment might be the existence of caps and/or floors on the volume of energy referenced in the VPPA or PPA, the likely volatility of volume of energy produced by the referenced producer, or other fair value drivers of the VPPA or PPA that do not exist in the designated hedged item. This is in addition to the usual consideration of any timing, pricing or index differences between the hedged item and hedging instrument. In any case, the difference in volume of energy that forms part of the hedged item and hedging instrument are likely to result in ineffectiveness (see section 7.4 below).

Given the identified challenges, specific questions relating to PPAs were submitted to the IFRS IC and escalated to the IASB in 2023.¹⁰ The IASB then added a maintenance project to the work plan to explore whether narrow-scope amendments could be made to IFRS 9 to better reflect how financial statements are affected by VPPAs and PPAs.¹¹ On 18 December 2024, the IASB published Amendments to IFRS 9 and IFRS 7 - Contracts Referencing Nature-dependent Electricity. The narrow scope amendments relate solely to contracts referencing nature-dependent electricity, which may not include all PPA or VPPA contracts. This is discussed further in section 3.2.6.A below.

3.2.6.A Amendments for Contracts Referencing Nature-dependent Electricity

On 18 December 2024, the IASB published Amendments to IFRS 9 and IFRS 7 - Contracts Referencing Nature-dependent Electricity ('the amendments').¹² The amendments:

- Address the application of the 'own-use' requirements for in-scope contracts
- Amend the designation requirements for a hedged item in a cash flow hedging relationship for in-scope contracts
- Add new disclosure requirements

The effective date of the amendments is for annual reporting periods beginning on or after 1 January 2026, with early application permitted. Prior to application of these amendments, the existing hedge accounting guidance discussed above in section 3.2.6 applies.

The amendments only apply to contracts that reference nature-dependent electricity. These are contracts that expose an entity to variability in an underlying amount of electricity because the source of electricity generation depends on uncontrollable natural conditions, typically associated with renewable electricity sources such as sun and wind ('in-scope contracts').

Contracts referencing nature-dependent electricity include contracts to buy or sell nature-dependent electricity (e.g. physical power purchase agreements), as well as financial instruments that reference such electricity (e.g. virtual power purchase agreements). The amendments cannot be applied by analogy to other contracts, items or transactions.

The IASB has clarified that other contracts, for example, contracts for electricity generated from biofuel, are not within the scope of the amendments because such electricity generation is not subject to the same uncertainty as in-scope contracts. [IFRS 9.2.3A, IFRS 9.2.3B, IFRS 9.BC2.17G].

How we see it

The amendments scope in contracts for nature-dependent electricity that are both physically and virtually settled. However, the amendments do not cover the accounting for renewable energy certificates (RECs), which typically accompany these contracts. The intention is for the scope to be narrow enough to minimise the risk of unintended consequences.

See Chapter 41 for details regarding the scope criteria of the amendments as well as the amendments to the own use exception, and Chapter 50 for details on the new disclosure requirements.

To overcome the challenges in achieving hedge accounting with contracts for nature-dependent electricity as hedging instruments (see section 3.2.6 above), the amendments will now allow an entity designating a contract referencing nature-dependent electricity as the hedging instrument in a hedge of forecast electricity transactions (for both purchases and sales), to designate a variable nominal amount of forecast electricity transactions as the hedged item. This designated variable nominal amount must be aligned with the variable amount of nature-dependent electricity expected to be delivered by the generation facility as referenced in the hedging instrument. [IFRS 9.6.10.1].

The amendments also state that if the cash flows of an in-scope contract designated as a hedging instrument are conditional on the occurrence of the forecast transaction that is designated as the hedged item in accordance with the amendments, this forecast transaction is presumed to be highly probable. [IFRS 9.6.10.2].

¹⁰ [IFRIC update](#), June 2023, available on the IFRS Foundation's website.

¹¹ [IASB update](#), July 2023, available on the IFRS Foundation's website.

¹² [IFRS - IASB updates IFRS Accounting Standards for nature-dependent electricity contracts](#)

When assessing the hedge effectiveness requirements (see section 6.4 below) and measuring ineffectiveness (see section 7.4 below) for hedging relationships within the scope of the amendments, the same volume assumptions should be applied to the hedged item as those used for measuring the hedging instrument. The hedging relationship would, therefore, not be affected by any mismatch caused by a comparison of a fixed volume of energy with a variable volume. [IFRS 9.IE158].

The other hedge accounting requirements of IFRS 9 continue to apply unchanged. In particular, all the other assumptions and inputs used for measuring the hedged item, including pricing assumptions, must reflect the nature and characteristics of the hedged item and must not impute the features of the hedging instrument (see section 7.4.4 below). [IFRS 9.6.10.1, IFRS 9.BC6.678].

How we see it

Although the amendments provide a practical solution for in-scope contracts and should avoid hedge ineffectiveness due to volume uncertainty, entities must be aware that there may still be other sources of ineffectiveness in the hedging relationship. For example, ineffectiveness can arise due to differences between the timing and volume of spot purchases and the actual deliveries used to calculate the cash flows under the contract referencing nature dependent electricity; or basis differences between the spot price in the market in which forecast purchases are made (the hedged risk) and the market in which the contract referencing nature dependent electricity is settled.

The hedge accounting amendments must be applied prospectively to new hedging relationships designated on or after the date of initial application. An entity is permitted to discontinue a hedging relationship in which an in-scope contract has been designated as the hedging instrument, if the same hedging instrument is then designated in a new hedging relationship under the amendments. [IFRS 9.7.2.53].

The prospective nature of application means that any contracts for nature-dependent electricity transacted prior to the date of initial application that are designated as hedging instrument will have a non-zero fair value on designation, this is often an additional source of ineffectiveness (see section 7.4.3 below). [IFRS 9.BC7.107].

The following example is largely derived from an example the IASB added to the Illustrative Examples to demonstrate the application of the amendments. It illustrates a possible way that an entity could designate forecasted electricity purchases with a variable nominal amount as the hedged item in a cash flow hedge.

Illustration 3-7: Cash flow hedge of variable nominal amount using contracts referencing nature-dependent electricity as hedging instruments

This fact pattern is based on Example 19 in the Illustrative Examples. [IFRS 9.IE148-159].

Entity A is a machine manufacturer in Region One and purchases electricity from the market in that region as and when it needs electricity (that is, on-demand). To hedge the unit price per megawatt hour (MWh) purchased, Entity A enters into a 25-year virtual power purchase agreement with Wind Farm X, which generates and delivers renewable electricity to the market in Region Two.

For the purpose of applying the amendments, it has already been determined that the contract qualifies as an in-scope contract referencing nature-dependent electricity. Entity A wants to designate this contract as a hedging instrument in a cash flow hedge to hedge the cash flow variability of future electricity purchases.

Hedge designation

Entity A designates as a cash flow hedge the hedging relationship between:

- a) its forecast electricity purchases in Region One for a term of 25 years (as the hedged item); and
- b) the contract for nature-dependent electricity (as the hedging instrument).

In line with its risk management strategy, Entity A wants to designate as the hedged item a variable nominal amount of electricity purchases per month that is aligned to the variable nominal amount of electricity that Wind Farm X is expected to deliver to the market as referenced in the hedging instrument. Entity A allocates the first purchases made each month to the variable nominal amount designated.

Entity A uses a probability-based assessment to determine whether the designated amount of electricity purchases for each month is highly probable (see section 2.6.1 above). It expects its monthly electricity purchases to continue over the hedged term, based on its current and past practice (that is, at the time of designation Entity A does not have any information to the contrary). Based on the probability assessment, Entity A determines that it is highly probable that the amount of the entity's forecast electricity purchases will be higher than or equal to the variable nominal amount designated as the hedged item.

Hedge effectiveness requirements

To assess the effectiveness of the hedging relationship, Entity A assesses whether there is an economic relationship between the hedged item (future electricity purchases) and the hedging instrument (the contract referencing nature-dependent electricity). Although Entity A purchases future electricity in Region One and Wind Farm X delivers nature-dependent electricity to Region Two, this difference in reference markets does not preclude an economic relationship (see section 6.4.1 below).

However, Entity A identifies two potential sources of ineffectiveness. The first is the basis risk associated with the variation in market prices of electricity between Region One and Region Two. The second is structural price differences—that is, the difference in the forecast market prices of electricity at the time of purchases to meet electricity demand of Entity A (reflected in the hedged item) and the forecast market prices at the time of delivery of electricity by Wind Farm X under the contract referencing nature-dependent electricity that are used to calculate the cash flows for net settlement (reflected in the hedging instrument).

For the forecast purchases of electricity, forecast market prices are modelled based on the expected future electricity spot price, which might vary depending on the timing of the purchase (for example, peak or off-peak). For example, Entity A might use an expected future baseload price in Region One and adjust that price for the timing of the expected consumption over a month, to reflect the actual timing of the purchase to meet demand. This method results in an average forecast market price per monthly volume purchased.

The forecast market prices for the volume expected to be delivered under the hedging instrument are also modelled based on the expected future electricity spot price. For example, Entity A might use an expected future baseload price in Region Two (as opposed to Region One because the hedging instrument is referencing a different spot market) adjusted for the expected production and hence the delivery profile of Wind Farm X for that same month. This method results in another average forecast market price for the same monthly volume, which might then lead to hedge ineffectiveness. Despite these sources of ineffectiveness, Entity A determines that an economic relationship exists. The other hedge effectiveness requirements are also assumed to be met in this example (see section 6 below).

Measurement of ineffectiveness

The variable nominal amounts of the hedged item and hedging instrument are both based on the variable volume of nature-dependent electricity Wind Farm X is expected to deliver to the electricity market in Region Two. Therefore, Entity A uses the same volume assumptions it uses to measure the contract referencing nature-dependent electricity to construct a hypothetical derivative to measure the changes in present value of the hedged item (see section 7.4.4 below). However, with regards to the forecast market prices, Entity A bases its assumptions on the characteristics of the respective markets as described above.

Entity A adjusts the cash flow hedge reserve to the lower of:

- a) the cumulative gain or loss on the hedging instrument from inception of the hedge; and
- b) the cumulative change in fair value (present value) of the hedged item (that is, the present value of the cumulative change in the hedged expected future cash flows, which for the volume assumptions only are aligned with the ones from the hedging instrument) from inception of the hedge.

For a more detailed explanation of the amendments see our publication *IFRS Developments: Nature-dependent electricity - IFRS 9 and IFRS 7 amendments*,¹³ and a helpful video *Amendments to IFRS 9 for nature-dependent electricity contracts*.¹⁴

3.3 Non-derivative financial instruments

Under IFRS 9, entities are permitted to designate, as hedging instruments, non-derivative financial assets or non-derivative financial liabilities that are accounted for at fair value through profit or loss. This is meant in a strict sense. Consequently, a liability designated as at fair value through profit or loss (for which the amount of its change in fair value that is attributable to changes in the credit risk of that liability is presented in other comprehensive income (OCI)) does not qualify as a hedging instrument (see Chapter 49). [IFRS 9.6.2.2]. This is because the entire fair value change is not recognised in profit or loss, which would in effect allow the entity to ignore its own credit risk when assessing and measuring hedge ineffectiveness and thus conflict with the concepts of hedge accounting. Illustration 3-8 below sets out an example of a risk management strategy for which a non-derivative financial instrument could be an eligible hedging instrument.

¹³ [Nature-dependent electricity - IFRS 9 and IFRS 7 amendments | EY - Global](#)

¹⁴ [Amendments to IFRS 9 for nature-dependent electricity contracts | EY - Global](#)

Illustration 3-8: Hedge of a forecast commodity purchase with an investment in a commodity fund or an exchange traded commodity

An entity is exposed to variability in cash flows from highly probable forecast purchases of crude oil that are indexed to Brent crude oil. The entity wants to hedge its cash flow risk from changes in the price of Brent crude oil. Instead of using derivative contracts, the entity purchases exchange traded investments that replicate the performance of Brent futures contracts such as commodity funds or exchange traded commodities (ETCs). ETCs have the legal form of bonds that are coupled to the price development of a commodity (either directly at the spot price or with a commodity futures contract). They can be traded like exchange traded funds but, because they are legally debt securities, they involve credit risk of the issuer (which is usually mitigated by collateralisation through physically deposited commodities or other suitable collateral).

These investments are financial instruments that (under IFRS 9) would be accounted for at fair value through profit or loss (see Chapter 44). Consequently, they could qualify as hedging instruments if all other qualifying criteria for hedge accounting are met (see section 6 below). In particular, the effectiveness assessment would have to take into account that the fair value change of the investments will differ from the present value of the cumulative change in the cash flows for the forecast purchases of crude oil (see section 6.4 below). This is because of aspects such as 'tracking errors' (i.e., that the investments do not perfectly replicate the performance of futures contracts) and that the investments are fully funded cash-instruments whereas the cash flows on the forecast transactions will only occur in the future.

The ability to designate non-derivative hedging instruments can be helpful if an entity does not have access to derivatives markets (e.g., because of local regulations that prohibit the entity from holding such instruments), or if an entity does not want to be subject to margining requirements nor enter into uncollateralised over-the-counter derivatives. Purchasing and selling financial investments in such cases can be operationally easier for entities than transacting derivatives.

IFRS 9 notes that: [IFRS 9.B6.2.5]

Extract from IFRS 9

B6.2.5 For hedges other than hedges of foreign currency risk, when an entity designates a non-derivative financial asset or a non-derivative financial liability measured at fair value through profit or loss as a hedging instrument, it may only designate the non-derivative financial instrument in its entirety or a proportion of it.

[IFRS 9.B6.2.5].

Portions and proportions of hedging instruments are discussed in section 3.6 below, but in the case of a non-derivative hedging instrument for a hedge other than of foreign currency risk, the guidance on portions is not applicable.

3.3.1 Hedge of foreign currency risk by a non-derivative financial instrument

For a hedge of foreign currency risk, the foreign currency component of a non-derivative financial asset or liability may be designated as a hedging instrument. [IFRS 9.6.2.2]. Non-derivative financial assets and liabilities need not be within the scope of IFRS 9 to qualify as hedging instruments. For example, although rights and obligations under lease agreements are for most purposes scoped out of IFRS 9, lease payables or finance lease receivables denominated in a foreign currency still meet the definition of a non-derivative financial instrument and are therefore eligible as hedging instruments in a hedge of foreign currency risk.

Consideration must be given to all the qualifying criteria before hedge accounting is applied (see section 6 below), in particular as to whether the designation is consistent with the risk management objective and strategy for managing the hedged exposure (see section 2.6.8 above).

An equity instrument for which an entity has elected to present changes in fair value in OCI does not qualify as a hedging instrument in a hedge of foreign currency risk. [IFRS 9.6.2.2]. This reflects that fair value changes (including from foreign currency risk) are not recognised in profit or loss, which is incompatible with the mechanics of fair value hedges and cash flow hedges.

For hedges of foreign currency risk, the foreign currency risk component of a non-derivative financial instrument is determined in accordance with IAS 21. [IFRS 9.B6.2.3]. This means that an entity could, for example, hedge the spot risk of highly probable forecast sales in 12 months' time that are denominated in a foreign currency with a 7-year financial liability in the same foreign currency. However, when measuring ineffectiveness, IFRS 9 is explicit that the revaluation of the forecast sales for foreign currency risk would have to be on a discounted basis (i.e., a present value calculation of the spot revaluation, reflecting the time between the reporting date and the future cash flow date), whereas the hedging instrument (i.e., the IAS 21-based foreign currency component of the financial liability) would not (see sections 7.4.2 and 7.4.7 below). This would result in some ineffectiveness. [IFRS 9.B6.5.4].

The following Illustration shows the types of permitted hedge relationships for foreign currency risk where the hedging instrument is a non-derivative financial instrument.

Illustration 3-9: Hedging with a non-derivative liability

Company J, which has GBP as its functional currency, has issued a fixed rate debt instrument with a principal due at maturity in two years of USD5 million. The debt is accounted for at amortised cost. J had also entered into a fixed price sales commitment, accounted for as an executory contract, for USD5 million that matures in two years as well.

J could not designate the debt instrument as a hedge of the exposure to *all* fair value changes of the fixed price sales commitment because the hedging instrument is a non-derivative liability that is not measured at fair value through profit or loss (and it would not be a good economic hedge anyway). However, J could designate the fixed rate debt instrument as a hedge of the foreign currency exposure associated with the future receipt of US dollars on the fixed price sales commitment.

In principle, there is no reason why a non-derivative financial instrument cannot be a hedging instrument in one hedge (of foreign currency risk) and a hedged item in another hedge (for example in a hedge of interest rate risk) (see section 3.6.2 below).

3.4 Own equity instruments

Extract from IFRS 9

B6.2.2 An entity's own equity instruments are not financial assets or financial liabilities of the entity and therefore cannot be designated as hedging instruments.

[IFRS 9.B6.2.2].

This prohibition would also apply to instruments that give rise to non-controlling interests in consolidated financial statements - under IFRS accounting standards it is clear that non-controlling interests are part of a reporting entity's equity (see Chapter 8).

3.5 Combinations of instruments

Extract from IFRS 9

6.2.5 An entity may view in combination, and jointly designate as the hedging instrument, any combination of the following (including those circumstances in which the risk or risks arising from some hedging instruments offset those arising from others):

- (a) derivatives or a proportion of them; and
- (b) non-derivatives or a proportion of them.

[IFRS 9.6.2.5].

Further discussion on designation of proportions is provided in section 3.6 below. There is a requirement that any combination can only be designated as a hedging instrument if the combination is not a net written option (see section 3.2.2 above).

Illustration 3-10: Hedging with a combination of a derivative and non-derivative instrument

Company K with the euro as its functional currency has issued a yen denominated floating rate borrowing and entered into a matching receive-yen floating (plus principal at maturity), pay-US dollar floating (plus principal at maturity) cross-currency interest rate swap. These instruments, which effectively synthesise a US dollar floating rate borrowing, contain offsetting terms, i.e., the whole of the borrowing and the yen leg of the swap. Company K could designate the combination of these two instruments in a hedge of the entity's foreign currency risk arising from, say, an asset with an identifiable exposure to US dollar exchange rates.

Designation of a combination of instruments as the hedging instrument does not change the unit of account for each individual instrument within the designated combination. Classification and measurement (see Chapter 44) and the usual eligibility criteria to be a hedging instrument (see section 3.1 above) are still applied to the individual instruments designated in combination as the hedging instrument. One exception is for the need for a hedging instrument to not be a net written option; this assessment should be made at the combined level, rather than at the individual instrument level (see section 3.2.2 above). The qualifying hedge accounting criteria and the associated incremental hedge accounting entries, however, are applied in consideration of the combination of instruments (see sections 6 and 7 below).

3.6 Portions and proportions of hedging instruments

In contrast to the position for hedged items (see section 2 above), there are significant restrictions on what components of an individual financial instrument can be carved out and designated as a hedging instrument. A qualifying instrument must be designated in its entirety as a hedging instrument, with only the following exceptions:

- A proportion of a hedging instrument (see section 3.6.1 below)
 - The time value of options could be separated (see section 3.6.4 below)
 - Forward elements of forward contracts could be separated (see section 3.6.5 below)
 - Foreign currency basis spread could be separated (see section 3.6.5 below) [IFRS 9.6.2.4]
 - The spot rate retranslation risk of a foreign currency non-derivative financial instrument could be separated (see section 3.3.1 above)
- And
- A derivative could be separated into notional component parts when each part is designated as a hedge and qualifies for hedge accounting (see section 3.6.2 below)

The hedge accounting guidance is applied only to the designated portion or proportion of the hedging instrument. However, if an entity chooses to separate the time value of an option, the forward element of a forward contract or the foreign currency basis spread from a hedge relationship, the costs of hedging guidance is also relevant (see section 7.5 below).

3.6.1 Proportions of instruments

It is possible to designate a proportion of the entire hedging instrument, such as 50% of the notional amount, in a hedging relationship. [IFRS 9.6.2.4(c)]. The proportion that is not designated is available for designation within other hedge relationships, such that a maximum of 100% of the notional is designated as a hedging instrument. Any proportions of an instrument not designated within hedge relationships are accounted for under the usual IFRS 9 classification and measurement guidance.

3.6.2 Hedging different risks with one instrument

Extract from IFRS 9

B6.2.6 A single hedging instrument may be designated as a hedging instrument of more than one type of risk, provided that there is a specific designation of the hedging instrument and of the different risk positions as hedged items. Those hedged items can be in different hedging relationships.

[IFRS 9.B6.2.6].

A single hedging instrument can also be used to hedge different risks within the same hedge relationship; one such frequent designation is of a single cross-currency swap used to hedge both foreign currency and interest rate risk in foreign currency debt.

An example where a single hedging derivative is used to hedge more than one risk in different hedging relationships is the use of a foreign currency forward to eliminate the resulting foreign currency risk from payables and receivables in two different foreign currencies, see Illustration 3-11 below, which is based on an example given in IAS 39. [IAS 39.F.1.13].

Illustration 3-11: Foreign currency forward used to hedge the position arising from two hedged items with different foreign currencies

Company L, which has Japanese yen as its functional currency, issues five-year floating rate US dollar debt and acquires a ten-year fixed rate sterling bond. The principal amounts of the asset and liability, when converted into Japanese yen, are the same. L enters into a single foreign currency forward contract to hedge its foreign currency exposure on both instruments under which it receives US dollars and pays sterling at the end of five years.

Company L designates the foreign currency forward as the hedging instrument in a cash flow hedge of foreign currency risk on both the sterling bond and the US dollar debt.

Designating a single hedging instrument as a hedge of multiple types of risk is permitted if there is specific designation of the hedging instrument and the different risk positions.

Company L has Japanese yen as its functional currency, hence it is exposed to JPY/GBP and USD/JPY foreign currency risk from the sterling bond and the US dollar debt, respectively. Separation of these different risk positions can be achieved by documentation of the principal repayment of the bond and debt in their respective currency of denomination as the hedged items in separate cash flow hedge relationships.

In order to achieve specific designation of the hedging instrument, it is effectively decomposed and viewed as two forward contracts, each with an offsetting position in yen, i.e., L's functional currency. Each of the decomposed forward contracts is then designated in an eligible hedge accounting relationship.

Even though the bond has a ten year life and the foreign currency forward only protects it for the first five years, hedge accounting is permitted for only a portion of the exposure (see section 2.2.4 above).

Accordingly hedge accounting could be achieved, but only if all the hedge accounting qualification criteria continue to be met (see section 6 below).

In the above example a single hedging instrument is designated in a hedge of foreign currency risk arising from two separate hedged items. The hedges in the example could both be designated as either cash flow or fair value hedges (see sections 5.1.2 and 5.2.3 below). There is no reason why a single hedging instrument could not be designated in both a cash flow hedge and a fair value hedge for different risks, provided the usual conditions for achieving hedge accounting are met.

Illustration 3-12: Cross-currency interest rate swap hedging two foreign currency exchange rate exposures and fair value interest rate exposure

Applying the same fact pattern as in Illustration 3-11 above, but in this case Company L wishes to hedge not only the foreign currency exposure on both the bond and the debt, but the fair value interest rate exposure on the bond as well. To do this Company L enters into a matching cross-currency interest rate swap to receive floating rate US dollars, pay fixed rate sterling and exchange the US dollars for sterling at the end of five years.

Similar to Illustration 3-11 above, the cross-currency interest rate swap is effectively decomposed and viewed as two cross-currency swaps, each with an offsetting leg in yen, i.e., L's functional currency, as follows:

- Decomposed swap 1: receive floating rate yen, pay fixed rate sterling and exchange the sterling for yen at the end of five years
And
- Decomposed swap 2: receive floating rate US dollars, pay floating rate yen and exchange the US dollars for yen at the end of five years

Therefore, the swap could be designated as a hedging instrument in separate hedges of the sterling bond and the US dollar liability as follows:

- Decomposed swap 1 designated in a fair value hedge (see section 5.1 below) as the hedging instrument against exposure to changes in present value of the sterling bond associated with the interest rate payments on the bond until year five and the change in present value of the principal payment due at maturity to the extent affected by changes in the yield curve relating to the five years of the swap (see Illustration 2-5 in section 2.2.4 above) as well as the exchange rate between sterling and yen.
- Decomposed swap 2 designated in a cash flow hedge (see section 5.2 below) as the hedging instrument against changes in all cash flows on the US dollar liability associated with USD/JPY foreign currency risk (see section 3.2.5 above).

Accordingly hedge accounting could be achieved, but only if all the hedge accounting qualification criteria continue to be met (see section 6 below).

As can be seen in Illustration 3-11 and Illustration 3-12 above, decomposition of a derivative hedging instrument by imputing notional legs is an acceptable means of splitting the fair value of a derivative hedging instrument into multiple components in order to achieve hedge accounting, as long as:

- The split does not result in the recognition of cash flows that are not evident from contractual terms of the derivative instrument
 - The notional legs introduced must be offsetting
 - All decomposed elements of the derivative instrument are included within an eligible hedge relationship
- And
- The designation is consistent with risk management (see section 6.2 below)

The IFRS IC confirmed such an approach to be acceptable under IAS 39 and there is no reason to believe that this would not also be the case under IFRS 9.¹⁵ Consideration of the hedge accounting qualifying criteria for all relationships that include decomposed elements of a derivative instrument must be captured in the hedge documentation on designation, as normal.

The qualifying criteria assessment could be carried out for the total hedged position, i.e., incorporating all risks identified if these risks are inextricably linked, or for the decomposed parts separately, i.e., individually for each hedge relationship that includes a decomposed part of the derivative. However, if the assessment is undertaken separately, each hedge relationship that includes a decomposed part would need to meet the qualifying criteria. Otherwise, the derivative would not qualify for hedge accounting as part of it would not be included within an eligible hedge relationship. This restriction is necessary as a financial instrument can only be designated as a hedging instrument in its entirety or an eligible portion or proportion thereof (see section 3.6 above). For example, the 'knock-out swap' in Illustration 3-3 in section 3.2.2 above could not be split into, on the one hand, a conventional interest rate swap, to be used as a hedging instrument and, on the other hand, the knock-out feature (a written swaption with a strike of 6%, i.e., an option for the counterparty to enter into an offsetting interest rate swap with the same terms as the conventional swap). This is because the knock-out feature is unlikely to be designated and qualify for hedge accounting at all.

If the IFRS IC analysis of the decomposition of derivatives is applied to a basis swap, hedge accounting for that swap could be possible (see section 3.2.5 above). The swap would be designated as a hedge of appropriate asset and liability positions.

Illustration 3-13: Designation of a basis swap hedging different risk positions

Entity X has made a USD1m loan that earns SOFR based interest and incurred a USD1m liability that pays interest based on the central bank rate (FED). Entity X transacts a basis swap under which it pays SOFR based interest and receives interest based on the FED rate on a notional amount of USD1m in order to eliminate the interest rate mismatch between the loan and the liability. In this case, the basis swap could be decomposed into two interest rate swaps, both with an offsetting USD1m fixed rate leg, to facilitate hedge designations for each of the SOFR loan and central bank rate deposit within separate cash flow hedges.

The guidance above discussed various combinations of cash flow and fair value hedge relationships. However, there appears to be no reason why a single instrument could not, in theory, be designated in other combinations of hedges, for example a cash flow hedge and a hedge of a net investment.

Further, there also appears to be no reason why a non-derivative foreign currency financial instrument could not be a hedging instrument for foreign currency risk, perhaps of a net investment, but also be the hedged item for changes in interest rate risk. This could be the case if the different risk positions were appropriately identified, and all the hedge accounting qualification criteria are met (see section 6 below).

3.6.3 Restructuring of derivatives

An entity could exchange a derivative that does not qualify as a hedging instrument (say, the knock-out swap in Illustration 3-3 in section 3.2.2 above) for two separate derivatives that, together, have the same fair value and risk profile as the original instrument (say, a conventional interest rate swap and a written swaption). Such an exchange is likely to be motivated by a desire to obtain hedge accounting for one of these new instruments.

¹⁵ [IFRIC Update](#), July 2007, available on the IFRS Foundation's website.

If a derivative that does not qualify as a hedging instrument is exchanged for two derivatives that, together, have the same characteristics as the original derivative, in order to determine whether the new arrangement can be treated as two separate derivatives, rather than a continuation of the original derivative, it is necessary to determine whether the exchange transaction has any substance, which is clearly a matter of judgement. If the exchange has no substance, then hedge accounting would still be precluded for either of the new derivatives, as the two 'separate' derivatives would in substance be a continuation of the original derivative (see section 3.2.1 above and Chapter 42).

In the case of the knock-out swap, if the two new contracts (e.g., a conventional interest rate swap and a swaption with a strike of 6%) had the same counterparty and, in aggregate, the same terms as the original contract this would not necessarily lead to the conclusion that the exchange lacked substance. However, if in addition, the swaption would be settled by delivery of the conventional interest rate swap in the event that it was exercised, this is a strong indicator that the exchange does lack substance.

3.6.4 Time value of options

An entity could choose to hedge for risk management purposes the variability of future cash flow outcomes resulting from a price increase (but not a decrease) of a forecast commodity purchase. This hedge of a 'one-sided risk' could be achieved by transacting a purchased option as the hedging instrument (see sections 3.2 and 3.2.2 above). In such a situation, it is permitted that only cash flow losses in the hedged item that result from an increase in the price above the specified level are designated within a hedge relationship. However, only the intrinsic value of a purchased option hedging instrument, not its time value, reflects this one-sided risk in the hedged item (assuming that it has the same principal terms as the designated risk). The hedged risk for a one-sided risk does not include the time value of a purchased option, because the time value is not a component of the forecast transactions that affects profit or loss (see section 7.4.12 below). [IFRS 9.B6.3.12]. As a result, changes in the time value of the option would give rise to hedge ineffectiveness.

To address this problem, an entity is permitted to designate as the hedging instrument only the change in the intrinsic value of an option and not the change in its time value. [IFRS 9.6.2.4(a)]. If it does so, the entity accounts for the time value of the option as a cost of hedging (see section 7.5 below). [IFRS 9.6.5.15].

How we see it

No prescriptive guidance is provided as to how the intrinsic value of an option must be calculated if it is designated in a hedging relationship. We believe it is acceptable to calculate the intrinsic value with respect to either the prevailing relevant spot or forward price, consistent with the risk management objective.

The chosen approach must also be documented and consistently applied for that hedge relationship. This would include an expectation that the intrinsic value calculated to represent the one-sided hedged risk in the hedged item was calculated in the same way as the intrinsic value of the option (see sections 2.1 above and 7.4.4 below).

Whilst it may be operationally simpler to calculate the intrinsic value with respect to the prevailing relevant spot price, in particular for an option contract with multiple exercise dates (e.g., a series of interest rate caplets), it is more common for market participants to view the intrinsic value with respect to the relevant forward prices.

Irrespective of whether the spot or forward price is used to determine the intrinsic value, there is an expectation that the calculation should be made on a discounted basis. By way of example, when using the forward price, the intrinsic value would be calculated by projecting each cash flow using the relevant forward price for the relevant date, and comparing that to the strike price. The result, if positive would then be discounted back to the valuation date and aggregated for all positive cash flows to form the intrinsic value of the option contract. A similar calculation would be made if using the spot price, but each cash flow comparison would be the prevailing spot price versus the strike price, however the discounting affect would be different for each cash flow (see section 7.4.7 below for further discussion on discounting of spot revaluations).

Excluding the time value could make it administratively easier to process the hedges and it can certainly improve a hedge's effectiveness from an accounting perspective. However, accounting for the option time value as a cost of hedging does involve some complexity, in particular where the terms of the hedged item and hedging option are what is described in the standard as not 'closely aligned' (see section 7.5.1.A below).

The use of this exception is not mandatory. For example, a dynamic hedging strategy that assesses both the intrinsic value and time value of an option contract can qualify for hedge accounting (see section 6.3.2 below), although the time value is still likely to result in some ineffectiveness. In addition, an entity could use an option to hedge an exposure that itself contains optionality - see section 7.4.12 below for the challenges that arise with such a designation.

3.6.5 Forward element of a forward contract and foreign currency basis spread

IFRS 9 also permits (but does not require) an entity to separate the forward element and the spot element of a forward contract and designate only the change in the value of the spot element of a forward contract and not the forward element as the hedging instrument.

In addition, the foreign currency basis spread may be separated and excluded from the designation of a financial instrument as the hedging instrument. [IFRS 9.6.2.4(b)].

Where the forward element or foreign currency basis are excluded from the designation as a hedging instrument, IFRS 9 permits a choice as to whether to account for the excluded portion as a cost of hedging (see section 7.5 below) or to continue measurement at fair value through profit or loss. This is, however, not an accounting policy choice, but an election for each designation. [IFRS 9.6.5.16].

3.6.6 Hedges of a portion of a time period

A hedging instrument cannot be designated for a part of its change in fair value that results from only a portion of the time period during which the hedging instrument remains outstanding. This clarifies that an entity cannot designate a 'partial-term' component of a financial instrument as the hedging instrument, but only the entire instrument for its remaining life (notwithstanding that an entity could exclude from designation the time value of an option, the forward element of a forward contract or the foreign currency basis spread, see sections 3.6.4 and 3.6.5 above). [IFRS 9.6.2.4]. This does not mean that the hedge relationship must necessarily continue for the entire remaining life of the hedging instrument - the usual hedge discontinuation requirements apply (see section 8.3 below).

Illustration 3-14: Designation of hedging instrument with longer life than hedged item

Entity T has an interest rate swap with a remaining maturity of five years and 6 months. Entity T wishes to designate the swap as the hedging instrument with respect to interest rate risk in issued debt that matures in five years.

It would not be possible for Entity T to designate only payments and receipts from the swap that occur over the next five years (i.e., ignoring those after year five) as the hedging instrument. Instead, the whole derivative (i.e., including payments and receipts after year five) could be designated as the hedging instrument, although the hedging relationship might itself last for only five years.

However, hedge accounting can only be applied if the hedge effectiveness criteria are met (see section 6.4 below), which might not necessarily be immediately obvious from a qualitative assessment if there are significant mismatches in maturity between the hedged item and the hedging instrument (see section 6.4.1 below).

4 Internal hedges and other group accounting issues

One of the most pervasive impacts that hedge accounting can have on groups, especially those operating centralised treasury functions, is the need to reassess hedging strategies that involve intragroup transactions. To a layman this might come as something of a surprise because the standard does little more than reinforce the general principle that transactions between different entities within a group will be eliminated in the consolidated financial statements of that group. Nevertheless, where risk is centrally managed, the requirement to identify eligible hedged items and hedging instruments with counterparties that are external to the reporting group, and to ensure the qualifying criteria are met, can be a challenge.

IAS 39 included a significant volume of Implementation Guidance devoted to the subject of internal hedges. The requirements in IFRS 9 for hedged items and hedging instruments to be with a party external to the reporting group (and the associated exemptions to this rule) are unchanged from the requirements in IAS 39. Therefore, much of the IAS 39 guidance is still relevant under IFRS 9 and is frequently referred to within this section.

4.1 Internal hedging instruments

The starting point for this guidance is the principle of preparing consolidated financial statements in IFRS 10 *Consolidated Financial Statements* that requires “intragroup assets and liabilities, equity, income, expenses and cash flows to be eliminated in full” (see Chapter 8). [IFRS 10.B86(c)].

Although individual entities within a consolidated group (or divisions within a single legal entity) might enter into hedging transactions with other entities within the group (or divisions within the entity), such as internal derivative contracts to transfer risk exposures between different companies (or divisions), any such intragroup (or intra-entity) transactions are eliminated on consolidation. Therefore, such hedging transactions do not qualify for hedge accounting in the consolidated financial statements of the group, (or in the individual or separate financial statements of an entity for hedging transactions between divisions of the entity). [IFRS 9.6.3.5, IAS 39.F.1.4]. Effectively, this is because they do not exist in an accounting sense.

Accordingly, IFRS 9 is very clear that for hedge accounting purposes, only instruments that involve a party external to the reporting entity (i.e., external to the group or individual entity that is being reported on) can be designated as hedging instruments (see section 3.1 above). [IFRS 9.6.2.3]. However, where an internal contract is offset with an external contract, the external contract could potentially be regarded as the hedging instrument. In such cases, the hedging relationship (which is between the external transaction and the item that is the subject of the internal hedge) could qualify for hedge accounting, as long as such a representation is directionally consistent with the actual risk management activities. Where the hedge designation does not exactly mirror an entity’s risk management activities it is commonly referred to as ‘proxy hedging’. The eligibility of proxy hedging designations was discussed by the IASB in their deliberations in developing IFRS 9 (see section 6.2.1 below).

The following Illustration shows the approach.

Illustration 4-1: Internal derivatives

The banking division of Bank A enters into an internal interest rate swap with Bank A’s trading division. The purpose is to hedge the interest rate risk exposure of a loan (or group of similar loans) in the banking division’s loan portfolio. Under the swap, the banking division pays fixed interest payments to the trading division and receives variable interest rate payments in return.

Assuming a hedging instrument is not acquired from an external party, hedge accounting treatment for the hedging transaction undertaken by the banking and trading divisions is not allowed, because only derivatives that involve a party external to the entity can be designated as hedging instruments. Further, any gains or losses on intragroup or intra-entity transactions will be eliminated on consolidation. Therefore, transactions between different divisions within Bank A cannot qualify for hedge accounting treatment in Bank A’s financial statements. Similarly, transactions between different entities within a group cannot qualify for hedge accounting treatment in Bank A’s consolidated financial statements.

However, if, in addition to the internal swap in the above example, the trading division entered into an interest rate swap or other contract with an external party that offset the exposure hedged in the internal swap, hedge accounting would be permitted. For the purposes of hedge accounting, the hedged item is the loan (or group of similar loans) in the banking division and the hedging instrument is the external interest rate swap or other contract.

The trading division could aggregate several internal swaps or portions of them that are not offsetting each other (see section 4.2 below) and enter into a single third-party derivative contract that offsets the aggregate exposure. Such external hedging transactions could qualify for hedge accounting treatment provided that suitable hedged items in the banking division are identified and the other conditions for hedge accounting are met. [IAS 39.F.1.4].

It follows that internal hedging instruments will only qualify for hedge accounting in the individual or separate financial statements of individual entities within the group, if they are external to the individual entity that is being reported on. [IFRS 9.6.2.3].

The IAS 39 Implementation Guidance contains the following summary of the application of IAS 39 to internal hedging transactions: [IAS 39.F.1.4]

Extract from IAS 39

F.1.4 Internal hedges

...

The following summarises the application of IAS 39 to internal hedging transactions.

- IAS 39 does not preclude an entity from using internal derivative contracts for risk management purposes and it does not preclude internal derivatives from being accumulated at the treasury level or some other central location so that risk can be managed on an entity-wide basis or at some higher level than the separate legal entity or division.
- Internal derivative contracts between two separate entities within a consolidated group can qualify for hedge accounting by those entities in their individual or separate financial statements, even though the internal contracts are not offset by derivative contracts with a party external to the consolidated group.
- Internal derivative contracts between two separate divisions within the same legal entity can qualify for hedge accounting in the individual or separate financial statements of that legal entity only if those contracts are offset by derivative contracts with a party external to the legal entity.
- Internal derivative contracts between separate divisions within the same legal entity and between separate entities within the consolidated group can qualify for hedge accounting in the consolidated financial statements only if the internal contracts are offset by derivative contracts with a party external to the consolidated group.
- If the internal derivative contracts are not offset by derivative contracts with external parties, the use of hedge accounting by group entities and divisions using internal contracts must be reversed on consolidation.

...

[IAS 39.F.1.4].

The premise on which the restriction on internal hedging instruments is based does not always hold. Foreign currency intragroup balances might well give rise to gains and losses in profit or loss under IAS 21 that are not fully eliminated on consolidation. To address this, the foreign currency risk of such intragroup monetary items, as well as certain forecast intragroup transactions, could qualify as a hedged item in the consolidated financial statements if the other conditions for hedge accounting are met (see section 4.3 below).

However, although internal transactions are sometimes permitted to be hedged items, even those internal transactions that affect consolidated profit or loss cannot be used in consolidated financial statements as hedging instruments. This is somewhat surprising as one might consider the same arguments that led to the exception permitting intragroup monetary items and forecast intragroup transactions to be hedged items for changes in foreign currency risk to support allowing intragroup monetary items to be hedging instruments. However, during its deliberations of the hedge accounting model under IFRS 9 the IASB decided to retain this restriction, and so the guidance is equally relevant in applying IFRS 9. [IFRS 9.BC6.148, IFRS 9.BC6.149].

IFRS 8 *Operating Segments* requires disclosure of segment information that is reported to the chief operating decision maker even if this is on a non-GAAP basis (see Chapter 32). Consequently, for a hedge to qualify for hedge accounting in segment reporting, it is not always necessary for the hedging instrument to involve a party external to the segment.

4.1.1 Central clearing parties and ring fencing of banks

Following the introduction of legal or regulatory requirements requiring over-the-counter (OTC) derivatives to be novated to a central clearing party (CCP) or incentivising financial institutions to do so (see section 8.3.5 below), coupled with additional legislation in various jurisdictions for banks to separate core retail banking activities from investment banking activities, additional focus has arisen on 'internal derivatives' within a banking group.

When derivatives transacted between the retail banking and investment banking legal entities within a banking group are novated to a CCP, the CCP becomes the counterparty to the derivatives. This does not automatically mean that the external derivatives with the CCP are eligible for hedge accounting; judgement will be required as to whether the offsetting external derivatives must be considered in substance as a single contract in the consolidated financial statements. As part of this judgement, consideration must be given to the substantive business purpose for the practice of transacting derivatives between the retail banking and investment banking legal entities and, in particular, novating derivatives to a CCP - other than to achieve hedge accounting (see section 3.2.1 above). The assessment as to whether such a substantive business purpose exists or not must be made based on the particular facts and circumstances, including consideration of the regulatory environment, and the judgement documented accordingly.

4.2 Offsetting internal hedging instruments

As noted in section 4.1 above, if an internal contract used in a hedging relationship is offset with an external party, the external contract could be regarded as a hedging instrument and the hedge could qualify for hedge accounting. The IAS 39 Implementation Guidance elaborates on this further in the context of both interest rate and foreign currency risk management, particularly in the situation where the exposures from internal derivatives are offset before being laid off with a third party.

4.2.1 Interest rate risk

Sometimes, central treasury functions enter into internal derivative contracts with subsidiaries and, perhaps, divisions within the consolidated group to manage interest rate risk on a centralised basis. As noted in section 4.1 above, the internal contracts cannot qualify for hedge accounting in the consolidated financial statements. If, before laying off the risk, the internal contracts are first netted against each other and only the net exposure is offset in the marketplace with external derivative contracts, it can be even harder to identify suitable hedging instruments in order to achieve hedge accounting in the consolidated financial statements.

Where two or more internal derivatives used to manage interest rate risk on assets or liabilities at the subsidiary or division level are offset at the treasury level, the effect of designating the internal derivatives as hedging instruments is that the hedged non-derivative exposures at the subsidiary or division levels would be used to offset each other on consolidation. Since IAS 39 did not permit designating non-derivatives as hedging instruments (except for foreign currency exposures), the results of hedge accounting from the use of internal derivatives at the subsidiary or division level that are not laid off with external parties had to be reversed on consolidation. [IAS 39.F.1.5]. Although IFRS 9 does permit designation of non-derivative instruments as hedging instruments, this is only for financial instruments measured at fair value through profit or loss, which is unlikely to be the case in this scenario (see section 3.3 above).

It should be noted, however, that if:

- The internal derivatives offset each other on consolidation
 - The internal derivatives are used in the same type of hedging relationship at the subsidiary or division level
 - The hedged items affect profit or loss in the same period (in the case of cash flow hedges)
- And
- The hedges are perfectly effective at the subsidiary level

Then there will be no effect on profit or loss and equity of reversing the effect of hedge accounting on consolidation.

Just as the internal derivatives offset at the treasury level, their use as fair value hedges by two separate entities or divisions within the consolidated group will also result in the offset of the fair value amounts recognised in profit or loss. Similarly, their use as cash flow hedges by two separate entities or divisions within the consolidated group will also result in the fair value amounts being offset against each other in other comprehensive income. [IAS 39.F.1.5].

However, reversal of subsidiary hedge accounting on consolidation could affect individual line items in both the consolidated income statement (or statement of comprehensive income) and the consolidated statement of financial position. This will be the case, for example, when internal derivatives that hedge assets (or liabilities) in a fair value hedge are offset by internal derivatives that are used as a fair value hedge of other assets (or liabilities) that are recognised in a different line item in the statement of financial position or income statement (or statement of comprehensive income). In addition, to the extent that one of the internal contracts is used as a cash flow hedge and the other is used in a fair value hedge, the effect on profit or loss and equity would not offset since the gain (or loss) on the internal derivative used as a fair value hedge would be recognised in profit or loss and the corresponding loss (or gain) on the internal derivative used as a cash flow hedge would be recognised in other comprehensive income. [IAS 39.F.1.5].

Notwithstanding this, under the principles set out in section 4.1 above, it could be possible to designate external derivative contracts as a hedge of some of the underlying exposures as shown in the following Illustration.

Illustration 4-2: Single external derivative offsets internal contracts on a net basis

Company A uses internal derivative contracts to transfer interest rate risk exposures from individual divisions to a central treasury function. The central treasury function aggregates the internal derivative contracts and enters into a single external derivative contract that offsets the internal derivative contracts on a net basis.

On one particular day the central treasury function enters into three internal receive-fixed, pay-variable interest rate swaps that lay off the exposure to variable interest cash flows on variable rate liabilities in other divisions and one internal receive-variable, pay-fixed interest rate swap that lays off the exposure to variable interest cash flows on variable rate assets in another division. It enters into an interest rate swap with an external counterparty that exactly offsets the net effect of the four internal swaps.

A cash flow hedge of an overall net position for interest rate risk does not qualify for hedge accounting under IFRS 9 (see section 2.5.3 above). However, designating a part of the variable rate assets or liabilities as the hedged position on a gross basis is permitted if the designation is directionally consistent with the actual risk management activities (see section 6.2.1 below). Therefore, even though the purpose of entering into the external derivative was to offset internal derivative contracts on a net basis, hedge accounting is permitted if the hedging relationship is defined and documented as a hedge of a part of the underlying cash inflows or cash outflows on a gross basis and assuming that the hedge accounting criteria are met. [IAS 39.F.2.15].

4.2.2 Foreign currency risk

Although much of the discussion in section 4.2.1 above applies equally to hedges of foreign currency risk, there is one important distinction between the two situations. Non-derivative financial instruments are permitted to be used as the hedging instrument in the hedge of foreign currency risk. Therefore, in this case, internal derivatives could be used as a basis for identifying non-derivative external transactions that could qualify as hedging instruments or hedged items, provided that the internal derivatives represent the transfer of foreign currency risk on underlying non-derivative financial assets or liabilities (see Cases 3 and 4 in Illustration 4-3 below). However, for consolidated financial statements, it is necessary to designate the hedging relationship so that it involves only external transactions.

Forecast transactions and unrecognised firm commitments cannot qualify as hedging instruments (see section 3.1 above). Accordingly, to the extent that two or more offsetting internal derivatives represent the transfer of foreign currency risk on such items, hedge accounting cannot be applied. As a result, if any cumulative net gain or loss on an internal derivative has been included in the initial carrying amount of an asset or liability (a 'basis adjustment') (see section 7.2.2 below), it would have to be reversed on consolidation if it cannot be demonstrated that the offsetting internal derivative represented the transfer of a foreign currency risk on a financial asset or liability to an external hedging instrument. [IAS 39.F.1.6]. This means that the other side of the internal derivative would need to be matched by the foreign currency risk on an external financial instrument, which could be designated as the hedging instrument.

The following Illustration shows this principle of using internal derivatives to identify suitable external hedging instruments - it also illustrates the mechanics of accounting for fair value hedges and cash flow hedges, which are discussed in more detail in sections 7.1 and 7.2 below. [IAS 39.F.1.7].

Illustration 4-3: Using internal derivatives to hedge foreign currency risk

In each of the following cases, 'FC' represents a foreign currency, 'LC' represents the local currency (which is the entity's functional currency) and 'TC' the group's treasury centre.

Case 1: Offset of hedges of foreign currency denominated monetary items

Subsidiary A has trade receivables of FC100, due in 60 days, which it hedges using a forward contract with TC. Subsidiary B has payables of FC50, also due in 60 days, which it hedges using a forward contract with TC.

TC nets the two internal derivatives and enters into a net external forward contract to pay FC50 and receive LC in 60 days.

At the end of month 1, FC weakens against LC. A incurs a foreign currency loss of LC10 on its receivables, offset by a gain of LC10 on its forward contract with TC. B makes a foreign currency gain of LC5 on its payables, offset by a loss of LC5 on its forward contract with TC. TC makes a loss of LC10 on its internal forward contract with A, a gain of LC5 on its internal forward contract with B and a gain of LC5 on its external forward contract.

Accordingly, the following entries are made in the individual or separate financial statements of A, B and TC at the end of month 1 (assuming that forward foreign currency and spot exchange rates are exactly the same, which is unlikely in reality). Entries reflecting intragroup transactions or events are shown in italics.

A's entries		LC	LC
Dr	Foreign currency loss	10	
Cr	Receivables		10
Dr	<i>Internal contract (TC)</i>	10	
Cr	<i>Internal gain (TC)</i>		10
B's entries		LC	LC
Dr	Payables	5	
Cr	Foreign currency gain		5
Dr	<i>Internal loss (TC)</i>	5	
Cr	<i>Internal contract (TC)</i>		5
TC's entries		LC	LC
Dr	<i>Internal loss (A)</i>	10	
Cr	<i>Internal contract (A)</i>		10
Dr	<i>Internal contract (B)</i>	5	
Cr	<i>Internal gain (B)</i>		5
Dr	External forward contract	5	
Cr	Foreign currency gain		5

Both A and B could apply hedge accounting in their individual financial statements provided all the necessary conditions were met. However, because gains and losses on the internal derivatives and the offsetting losses and gains on the hedged receivables and payables are recognised immediately in profit or loss without hedge accounting (as required by IAS 21), hedge accounting is unnecessary (see section 7.2.3 below for further information on hedges of foreign currency denominated monetary items).

In the consolidated financial statements, the internal derivative transactions are eliminated. In economic terms, B's payable hedges FC50 of A's receivables. The external forward in TC hedges the remaining FC50 of A's receivable. In the consolidated financial statements, hedge accounting is again unnecessary because monetary items are measured at spot foreign currency rates under IAS 21 irrespective of whether hedge accounting is applied.

The net balances, before and after elimination of the accounting entries relating to the internal derivatives, are the same, as set out below. Accordingly, there is no need to make any further accounting entries to meet the requirements of IFRS 9.

	DR	CR
	LC	LC
Receivables	-	10
Payables	5	-
External forward contract	5	-
Gains and losses	-	-
Internal contracts	-	-

Case 2: Offset of cash flow hedges

To extend the example, A also has highly probable future revenues of FC200 on which it expects to receive cash in 90 days. B has highly probable future expenses of FC500 (advertising cost), also to be paid for in 90 days. A and B enter into separate forward contracts with TC to hedge these exposures and TC enters into an external forward contract to receive FC300 in 90 days.

As before, FC weakens at the end of month 1. A incurs a 'loss' of LC20 on its anticipated revenues because the LC value of these revenues decreases and this is offset by a gain of LC20 on its forward contract with TC. Similarly, B incurs a 'gain' of LC50 on its anticipated advertising cost because the LC value of the expense decreases and this is offset by a loss of LC50 on its transaction with TC.

TC incurs a gain of LC50 on its internal transaction with B, a loss of LC20 on its internal transaction with A and a loss of LC30 on its external forward contract.

Both A and B satisfy the hedge accounting criteria and qualify for hedge accounting in their individual financial statements. A recognises the gain of LC20 on its internal derivative transaction in other comprehensive income and B does the same with its loss of LC50. TC does not claim hedge accounting, but measures both its internal and external derivative positions at fair value, which net to zero.

Accordingly, the following entries are made in the individual or separate financial statements of A, B and TC at the end of month 1. Entries reflecting intragroup transactions or events are shown in italics.

A's entries		LC	LC
<i>Dr</i>	<i>Internal contract (TC)</i>	20	
<i>Cr</i>	<i>Other comprehensive income</i>		20
B's entries		LC	LC
<i>Dr</i>	<i>Other comprehensive income</i>	50	
<i>Cr</i>	<i>Internal contract (TC)</i>		50
TC's entries		LC	LC
<i>Dr</i>	<i>Internal loss (A)</i>	20	
<i>Cr</i>	<i>Internal contract (A)</i>		20
<i>Dr</i>	<i>Internal contract (B)</i>	50	
<i>Cr</i>	<i>Internal gain (B)</i>		50
<i>Dr</i>	<i>Foreign currency loss</i>	30	
<i>Cr</i>	<i>External forward contract</i>		30

IFRS 9 requires that, in the consolidated financial statements, the accounting effects of the internal derivative transactions must be eliminated.

If there were no hedge designation for the consolidated financial statements, the gains and losses recognised in other comprehensive income and profit or loss on the internal derivatives would be reversed. Consequently, a loss of LC30 would be recognised in profit or loss in respect of the external forward contract held by TC.

However, for the consolidated financial statements, TC's external forward contract on FC300 can be designated, at the beginning of month 1, as a hedging instrument of the first FC300 of B's highly probable future expenses. Therefore, LC30 of the gain recognised in other comprehensive income by B could remain in other comprehensive income on consolidation, because it involves an external derivative. Accordingly, the net balances, before and after elimination of the accounting entries relating to the internal derivatives, are as set out below and there is no need to make any further accounting entries.

	DR	CR
	LC	LC
External forward contract	-	30
Other comprehensive income	30	-
Gains and losses	-	-
Internal contracts	-	-

Case 3: Offset of hedges of foreign currency denominated monetary items and cash flow hedges

The example is extended further and it is assumed that the exposures and the internal derivative transactions are the same as in Cases 1 and 2. In other words, Subsidiary A has trade receivables of FC100, due in 60 days, and highly probable future revenues of FC200 on which it expects to receive cash in 90 days. Subsidiary B has payables of FC50, due in 60 days, and highly probable future expenses of FC500 to be paid for in 90 days. Each of these exposures is hedged using forward contracts with TC. However, in this case, instead of entering into two external derivatives to hedge separately the fair value and cash flow exposures, TC enters into a single net external derivative to receive FC250 in exchange for LC in 90 days.

Consequently, TC has four internal derivatives, two maturing in 60 days and two maturing in 90 days. These are offset by a net external derivative maturing in 90 days. The interest rate differential (and hence forward points) between FC and LC is minimal, and therefore the ineffectiveness resulting from the mismatch in maturities is expected to have a minimal effect on profit or loss in TC, and so has been ignored for the purposes of this example (see section 7.4.2 below).

As in Cases 1 and 2, A and B apply hedge accounting for their cash flow hedges and TC measures its derivatives at fair value. A recognises a gain of LC20 on its internal derivative transaction in other comprehensive income and B does the same with its loss of LC50.

Accordingly, the following entries are made in the individual or separate financial statements of A, B and TC at the end of month 1. Entries reflecting intragroup transactions or events are shown in *italics*.

A's entries		LC	LC
Dr	Foreign currency loss	10	
	Cr Receivables		10
Dr	<i>Internal contract (TC)</i>	10	
	Cr <i>Internal gain (TC)</i>		10
Dr	<i>Internal contract (TC)</i>	20	
	Cr <i>Other comprehensive income</i>		20
B's entries		LC	LC
Dr	Payables	5	
	Cr Foreign currency gain		5
Dr	<i>Internal loss (TC)</i>	5	
	Cr <i>Internal contract (TC)</i>		5
Dr	<i>Other comprehensive income</i>	50	
	Cr <i>Internal contract (TC)</i>		50
TC's entries		LC	LC
Dr	<i>Internal loss (A)</i>	10	
	Cr <i>Internal contract (A)</i>		10
Dr	<i>Internal loss (A)</i>	20	
	Cr <i>Internal contract (A)</i>		20
Dr	<i>Internal contract (B)</i>	5	
	Cr <i>Internal gain (B)</i>		5
Dr	<i>Internal contract (B)</i>	50	
	Cr <i>Internal gain (B)</i>		50
Dr	Foreign currency loss	25	
	Cr External forward contract		25

The gains and losses recognised on the internal contracts in A and B can be summarised as follows:

	A	B	Total
	LC	LC	LC
Profit or loss (hedge of receivable/payables)	10	(5)	5
Other comprehensive income (hedge of revenue/expenses)	20	(50)	(30)
Total	30	(55)	(25)

In the consolidated financial statements, IFRS 9 requires the accounting effects of the internal derivative transactions to be eliminated.

If there were no hedge designation for the consolidated financial statements, the gains and losses recognised in other comprehensive income and profit or loss on the internal derivatives would be reversed. Consequently, a loss of LC30 would be recognised in profit or loss, made up of a net loss of LC5 in respect of the external receivable and payable held by A (loss LC10) and B (gain LC5), respectively, and the external forward contract held by TC (loss LC25).

However, for the consolidated financial statements, the following cash flow hedge designations can be made at the beginning of month 1:

- The payable of FC50 in B is designated as a hedge of the first FC50 of the highly probable future revenues in A.

Therefore, at the end of month 1, the following entries are made in the consolidated financial statements:
Dr Payable LC5; Cr Other comprehensive income LC5.

- The receivable of FC100 in A is designated as a hedge of the first FC100 of the highly probable future expenses in B.

Therefore, at the end of month 1, the following entries are made in the consolidated financial statements:
Dr Other comprehensive income LC10, Cr Receivable LC10.

And

- The external forward contract on FC250 in TC is designated as a hedge of the next FC250 of highly probable future expenses in B.

Therefore, at the end of month 1, the following entries are made in the consolidated financial statements:
Dr Other comprehensive income LC25; Cr External forward contract LC25.

Combining these entries produces the total net balances as follows:

	DR	CR
	LC	LC
Receivables	-	10
Payables	5	-
External forward contract	-	25
Other comprehensive income	30	-
Gains and losses	-	-
Internal contracts	-	-

Based on this designation, the total net balances achieved in the consolidated financial statements at the end of month 1 are the same as those that would be recognised if the hedge accounting effect of the internal derivatives were not eliminated. However, it should be noted this is a simplified example and any difference in timing between the hedged item and hedging instrument is assumed to have a minimal effect on profit or loss, and so no effect has been reflected here. This will not necessarily be the case in reality, therefore some additional ineffectiveness is likely to occur in the consolidated financial statements. For example, as the FC50 payable in B due in 60 days is designated as a hedge of the first FC50 of the highly probable future revenues in A expected to occur in 90 days, this difference in timing could result in ineffectiveness (see section 7.4.2 below).

Case 4: Offset of hedges of foreign currency denominated monetary items and cash flow hedges with adjustment to carrying amount of inventory

Similar transactions to those in Case 3 are assumed except that the anticipated cash outflow of FC500 in B relates to the purchase of inventory that is delivered after 60 days. When the inventory is recognised, the entity applies a basis adjustment to the hedged forecast non-financial items as required by IFRS 9 (see section 7.2.2 below).

To recap, Subsidiary A has trade receivables of FC100, due in 60 days, and highly probable future revenues of FC200 on which it expects to receive cash in 90 days. Subsidiary B has payables of FC50, due in 60 days, and a highly probable future purchase of inventory for FC500, to be delivered in 60 days and paid for in 90 days. Each of these exposures is hedged using forward contracts with TC, and TC enters into a single net external derivative to receive FC250 in exchange for LC in 90 days.

At the end of month 2, there are no further changes in exchange rates or fair values. At that date, the inventory is delivered and the loss of LC50 on B's internal derivative, recognised in other comprehensive income in month 1, is removed from equity and adjusts the carrying amount of inventory in B. The gain of LC20 on A's internal derivative hedging the highly probable future revenue remains in other comprehensive income as before.

In the consolidated financial statements, there is now a mismatch compared with the result that would have been achieved by unwinding and redesignating the hedges. The external derivative (FC250) and the proportion of receivable (FC50) in A offset FC300 of the anticipated inventory purchase in B. Offset will occur between the FC50 payable in B and a FC50 proportion of the receivable in A. There is a natural hedge between the remaining FC200 of anticipated cash outflow in B (inventory) and the anticipated cash inflow of FC200 in A (revenue). This last relationship would not qualify for hedge accounting under IFRS 9 as no valid hedging instrument exists, but as noted, hedge accounting is not required given the natural hedge achieved.

Accordingly, the following entries are made in the individual or separate financial statements of A, B and TC at the end of month 1. Entries reflecting intragroup transactions or events are shown in italics.

A's entries (all at the end of month 1)		LC	LC
Dr	Foreign currency loss	10	
	Cr Receivables		10
Dr	<i>Internal contract (TC)</i>	10	
	Cr <i>Internal gain (TC)</i>		10
Dr	<i>Internal contract (TC)</i>	20	
	Cr <i>Other comprehensive income</i>		20
B's entries (at the end of month 1)		LC	LC
Dr	Payables	5	
	Cr Foreign currency gain		5
Dr	<i>Internal loss (TC)</i>	5	
	Cr <i>Internal contract (TC)</i>		5
Dr	<i>Other comprehensive income</i>	50	
	Cr <i>Internal contract (TC)</i>		50
B's entries (at the end of month 2)		LC	LC
Dr	Inventory	50	
	Cr Other comprehensive income		50
TC's entries (all at the end of month 1)		LC	LC
Dr	<i>Internal loss (A)</i>	10	
	Cr <i>Internal contract (A)</i>		10
Dr	<i>Internal loss (A)</i>	20	
	Cr <i>Internal contract (A)</i>		20
Dr	<i>Internal contract (B)</i>	5	
	Cr <i>Internal gain (B)</i>		5
Dr	<i>Internal contract (B)</i>	50	
	Cr <i>Internal gain (B)</i>		50
Dr	Foreign currency loss	25	
	Cr External forward contract		25

The gains and losses recognised on the internal contracts in A and B can be summarised as follows:

	A	B	Total
	LC	LC	LC
Profit or loss (hedge of receivables/payables)	10	(5)	5
Other comprehensive income (hedge of revenue)	20	-	20
Basis adjustment (hedge of inventory)	-	(50)	(50)
Total	30	(55)	(25)

Combining these amounts with the external transactions (i.e., those not marked in italics above) produces the total net balances before elimination of the internal derivatives and unwind of associated ineligible hedge relationships as follows:

	DR	CR
(At the end of month 2)	LC	LC
Receivables	-	10
Payables	5	-
External forward contract	-	25
Other comprehensive income	-	20
Basis adjustment (inventory)	50	-
Gains and losses	-	-
Internal contracts	-	-

For the consolidated financial statements, the following cash flow hedge designations can be made at the beginning of month 1:

- The payable of FC50 in B is designated as a hedge of the first FC50 of the highly probable future revenues in A.
Therefore, at the end of month 1, the following entry is made in the consolidated financial statements: Dr Payables LC5; Cr Other comprehensive income LC5.
- The receivable of FC100 in A is designated as a hedge of the first FC100 of the highly probable future inventory purchase in B.
Therefore, at the end of month 1, the following entries are made in the consolidated financial statements: Dr Other comprehensive income LC10; Cr Receivable LC10; and at the end of month 2, Dr Inventory LC10; Cr Other comprehensive income LC10.
- The external forward contract on FC250 in TC is designated as a hedge of the next FC250 of highly probable future inventory purchase in B.
Therefore, at the end of month 1, the following entry is made in the consolidated financial statements: Dr Other comprehensive income LC25; Cr External forward contract LC25; and at the end of month 2, Dr Inventory LC25; Cr Other comprehensive income LC25.

This leaves FC150 of the future revenue in A and FC150 of future inventory purchase in B not designated in a hedge accounting relationship in the consolidated financial statements. The accounting consequence of this is discussed below.

The total net balances after elimination of the accounting entries relating to the internal derivatives and application of the eligible hedge designations above, are as follows:

	DR	CR
(At the end of month 2)	LC	LC
Receivables	-	10
Payables	5	-
External forward contract	-	25
Other comprehensive income	-	5
Basis adjustment (inventory)	35	-
Gains and losses	-	-
Internal contracts	-	-

These total net balances are different from those that would be recognised if the internal derivatives were not eliminated, and it is these net balances in the table above that IFRS 9 requires to be included in the consolidated financial statements. The accounting entries required to adjust the total net balances to eliminate the effect of the internal derivatives are as follows:

- To reclassify LC15 of the loss on B's internal derivative that is included in inventory to reflect that FC150 of the forecast purchase of inventory is not hedged by an external instrument (i.e., the external forward contract of FC250 in TC and the external payable of FC100 in A can hedge a maximum of FC350 of the forecast purchase of inventory).

And

- To reclassify the gain of LC15 on A's internal derivative to reflect that the forecast revenues of FC150 to which it relates is not hedged by an external instrument.

The net effect of these two adjustments is as follows:

		LC	LC
Dr	Other comprehensive income	15	
	Cr Inventory		15

It is apparent that extending the principles set out in this relatively simple example to the more complex and higher volume situations that are likely to be encountered in practice is not going to be straightforward.

4.3 Internal hedged items

Only assets, liabilities, firm commitments or highly probable forecast transactions that involve a party external to the entity can be designated as hedged items. It follows that hedge accounting can be applied to transactions between entities in the same group only in the individual or separate financial statements of those entities and not in the consolidated financial statements of the group. [IFRS 9.6.3.5]. However, there are two exceptions with respect to foreign currency risk - intragroup monetary items and certain forecast intragroup transactions, discussed in sections 4.3.1 and 4.3.2 below.

4.3.1 Intragroup monetary items

IFRS 9 allows the foreign currency risk of an intragroup monetary item (e.g., a payable or receivable between two subsidiaries) to qualify as a hedged item in the consolidated financial statements if it results in an exposure to foreign exchange rate gains or losses under IAS 21 that are not fully eliminated on consolidation. Foreign exchange gains and losses on such items are not fully eliminated on consolidation when they are transacted between two group entities that have different functional currencies (see Chapter 16), [IFRS 9.6.3.6], as shown in the following Illustration.

Illustration 4-4: Hedge of intragroup foreign currency trade receivable

Company A has two subsidiaries, Company B and Company C. A and B have the euro as their functional currencies, while C has the US dollar as its functional currency. On 31 March, C purchases goods from B for US\$110, payable on 30 June.

In this case, the intragroup trade receivable of US\$110 could be designated as a hedged item in a hedge of foreign currency risk both by B in its separate financial statements and by A in its consolidated financial statements.

While B's foreign currency receivable is eliminated against C's foreign currency payable on consolidation, the exchange differences that arise for B cannot be eliminated since C has no corresponding exchange differences.

Thus, the intragroup monetary item results in an exposure to variability in the foreign currency amount of the intragroup monetary item that will affect profit or loss in the consolidated financial statements. Therefore, the intragroup monetary item could be designated as a hedged item in a foreign currency hedge.

In order to hedge the US\$/euro foreign currency risk from the US\$ intragroup trade receivable, B transacts a forward foreign currency contract to sell US\$ and buy euros. If no hedge accounting was applied in A's consolidated financial statements, then the combination of the exchange difference recognised on B's intragroup foreign currency trade receivable and the fair value changes in the forward foreign currency contract would largely offset in consolidated profit or loss. However, residual profit or loss volatility from fair value movements in the forward element of the forward foreign currency contract could be reduced by hedge accounting, for example, by designating the forward foreign currency risk or application of the costs of hedging accounting for the forward element (see sections 7.2.3 and 7.5.2 respectively below).

The exception above relates solely to the eligibility of certain foreign currency intragroup monetary items as hedged item in the consolidated financial statements. An equivalent exception does not exist to allow

such items to be designated as hedging instruments in the consolidated financial statements (see section 4.1 above).

4.3.2 Forecast intragroup transactions

IFRS 9 also contains a second exception allowing the foreign currency risk of a highly probable forecast intragroup transaction to qualify as a hedged item in a cash flow hedge in consolidated financial statements in certain circumstances. The transaction must be denominated in a currency other than the functional currency of the entity entering into that transaction (e.g., parent, subsidiary, associate, joint venture or branch) and the foreign currency risk must affect consolidated profit or loss (otherwise it cannot qualify as a hedged item). [IFRS 9.6.3.6].

A forecast sale or purchase of inventory between members of the same group will affect profit or loss if there is an onward sale of the inventory to a party external to the group. Similarly, a forecast intragroup sale of plant and equipment from the group entity that manufactured it to a group entity that will use it in its operations may affect consolidated profit or loss. This could occur, for example, because the plant and equipment will be depreciated by the purchasing entity and the amount initially recognised for the plant and equipment may change if the forecast intragroup transaction is denominated in a currency other than the functional currency of the purchasing entity. [IFRS 9.B6.3.5].

Ordinarily, a related external transaction is required to exist in order that a forecast intragroup transaction could affect consolidated profit or loss, and hence be an eligible hedged item in the consolidated financial statements. In that case, it is clear that the designated hedged item is the forecast intragroup transaction, which is therefore subject to the usual eligibility criteria for hedge accounting (see section 2 above). However, the highly probable criterion (see section 2.6.1 above) is also relevant for the existence of the external transaction in order to meet the requirement that the forecast foreign currency risk will affect consolidated profit or loss. The related external transaction also drives the timing of recycling of the effective portion of the hedge relationship (see section 7.2.2 below). Illustrations 4-6 and 4-7 below provide examples of eligible hedged forecast intragroup transactions.

Illustration 4-5: Hedge of intragroup foreign currency forecast purchase of machinery

Subsidiary X and Y are both subsidiaries of Parent Z. Subsidiary X, which has GBP as its functional currency, builds machinery and has a highly probable forecast sale of machinery to Subsidiary Y in 6 months' time for £100m. Subsidiary Y, which has euro as its functional currency, expects to use the purchased machinery over a 10-year period in the production of goods. [IAS 16.6].

Y wishes to eliminate variability from GBP/euro foreign currency risk in the cost of the forecast machinery purchase and so transacts a forward foreign currency contract to buy £100m and sell €110m for settlement in 6 months' time.

In Y's separate financial statements Y could designate the forward foreign currency contract as a cash flow hedge of the GBP/euro foreign currency risk from the highly probable forecast purchase of machinery.

In Z's consolidated financial statements, the cash flow hedge would still be eligible as the euro carrying amount recognised by Y for the machinery will be depreciated and therefore ultimately impacts consolidated profit or loss.

The fact that Y expects to use the machinery in the production of goods is essential in order to justify recognition of the machinery as property plant and equipment under IAS 16 (see Chapter 19) and subsequent depreciation, otherwise the intragroup sale of machinery would be fully eliminated on consolidation (see Chapter 8).

Illustration 4-6: Hedge of intragroup foreign currency forecast purchase of inventory

Using the same fact pattern as in Illustration 4-5 above, but in this case, Subsidiary X has highly probable GBP sale of inventory to Subsidiary Y in 3 months time. Over the following 2 months, it is highly probable that Y will sell on the inventory externally.

Y wishes to eliminate variability from GBP/euro foreign currency risk in the cost of the forecast inventory purchase and so transacts a forward foreign currency contract to buy GBP and sell euro for settlement in 3 months' time.

In Y's separate financial statements Y could designate the forward foreign currency contract as a cash flow hedge of the GBP/euro foreign currency risk from the highly probable forecast purchase of inventory.

In Z's consolidated financial statements, the cash flow hedge would still be eligible as when revenue is eventually recognised on the highly probable external sales, consolidated profit or loss will be impacted by the cost of sale recognised from the intragroup sale of inventory. This means that consolidated profit or loss is ultimately affected by the foreign currency risk from the intragroup forecast purchase of inventory (see Chapter 8 and Chapter 16). In that case the GBP/euro foreign currency risk from the intragroup sale will affect consolidated profit or loss.

Over the subsequent 2 month period as Y sells the inventory externally, in Z's consolidated financial statements the effective portion of the cash flow hedge reserve will be recycled, as that is when the hedged risk impacts consolidated profit or loss.

Had the intragroup forecast sale of inventory been in a different foreign currency (e.g., US\$) and if Y had hedged the US\$/euro FX risk from those forecast purchases, such a hedge would not be eligible in Z's consolidated financial statements. This is because consolidated profit for this transaction will ultimately be impacted by GBP/euro foreign currency risk and not US\$/euro.

Normally, royalty payments, interest payments and management charges between members of the same group will not affect consolidated profit or loss unless there is a related external transaction. [IFRS 9.B6.3.5]. No further guidance is provided as to what is meant by a 'related external transaction'. However, by way of example, in consideration of the eligibility of intragroup royalty costs, if those intragroup royalties are an unavoidable part of the highly probable forecasted external sale, for example to reflect patented technical knowhow developed by one subsidiary that is necessary for another subsidiary to produce a product for sale, then perhaps that would be sufficient to demonstrate that the external sales are related external transactions for the purposes of determining the eligibility of the intragroup royalty payments as hedged items. For each fact pattern, consideration will need to be given as to whether a related external transaction exists and whether the consolidated profit or loss is therefore affected by the intragroup transaction.

How we see it

Although the standard refers exclusively to forecast intragroup transactions, we believe there is no reason why these provisions do not also apply to intragroup firm commitments. Hence an intragroup firm commitment may be an eligible hedged item if the criteria for this second exception are met.

Further, a highly probable dividend receivable from a wholly owned subsidiary could be an eligible hedged item in a cash flow hedge in the parent's separate financial statements. However, this would not be the case in the parent's consolidated financial statements as the dividend does not affect consolidated profit or loss (see section 2.6.6 above).

4.4 Hedged item and hedging instrument held by different group entities

The IAS 39 Implementation Guidance explained that, in a group, it is not necessary for the hedging instrument to be held by the same entity as the one that has the exposure being hedged in order to qualify for hedge accounting in the consolidated financial statements. [IAS 39.F.2.14]. This is shown in the following Illustration.

Illustration 4-7: Subsidiary's foreign currency exposure hedged by parent

Company S is based in Switzerland and prepares consolidated financial statements in Swiss francs. It has an Australian subsidiary, Company A, whose functional currency is the Australian dollar and is included in the consolidated financial statements of S. A has forecast purchases in Japanese yen that are highly probable and S enters into a forward contract to hedge the change in yen relative to the Australian dollar.

Because A did not hedge the foreign currency exchange risk associated with the forecast purchases in yen, the effects of exchange rate changes between the Australian dollar and the yen will affect A's profit or loss and, therefore, would also affect consolidated profit or loss. Therefore, that hedge could qualify for hedge accounting in S's consolidated financial statements provided the other hedge accounting criteria are met.

[IAS 39.F.2.14].

By contrast, if Company A also has forecast purchases in Australian dollars, and S enters into a forward contract to hedge the change in Australian dollar relative to the Swiss francs, hedge accounting would not be permitted as changes between the Australian dollar and Swiss francs will not affect A's profit or loss nor consequently S's consolidated profit or loss.

Whilst the above is based on Implementation Guidance from IAS 39, it would appear to be still relevant under IFRS 9, as was explicitly confirmed for hedges of net investments within IFRIC 16 *Hedges of a Net Investment in a Foreign Operation*. (See section 5.3.3 below).

One of the key qualifying criteria that must be met when a hedging instrument is held by a different group entity in a fair value or cash flow hedge, is that the hedged risk could affect profit or loss (see sections 5.1 and 5.2 below). This is illustrated using the fact pattern in Illustration 4-8.

Illustration 4-8: Subsidiary's foreign currency exposure hedged by parent (2)

Using the same fact pattern as in Illustration 4-7 above, but in this case S has instead entered into a forward contract to hedge the change in Swiss francs relative to Japanese yen.

S cannot achieve cash flow hedge accounting for the forward contract to sell Swiss francs and buy yen in S's consolidated financial statements as there is no cash flow variability with respect to the Swiss francs/yen exchange rates that will affect consolidated profit or loss.

Consolidated profit or loss will be impacted by movements in the yen/Australian dollar exchange rates, as subsidiary A will recognise the purchase at the prevailing yen/Australian dollar exchange rate (consistent with the designated risk in the hedging strategy in Illustration 4-7 above). [IAS 21.21].

S is exposed to Australian dollar/Swiss franc exchange rates on translation of the purchase on consolidation, but this is not a cash flow exposure. [IAS 21.39(b)].

Accordingly, cash flow hedge accounting cannot be achieved as the hedged risk (i.e., the change in Swiss francs relative to Japanese yen) does not affect consolidated profit or loss.

It is also a requirement that for the group entity entering into the hedging instrument (i.e., the hedging entity), remeasurement of that hedging instrument with respect to the foreign currency risk has an impact on consolidated profit or loss, as otherwise the mechanics of hedge accounting cannot be applied.

[IFRS 9.6.5.11(a)(i)]. This will usually be the case if the hedging instrument is a derivative but will not be if the hedging instrument is a monetary item in the same currency as the hedging entity's functional currency. This is illustrated using the fact pattern in Illustration 4-9.

Illustration 4-9: Group hedging entity has functional currency that is the same as the hedged exposure

Company UK is based in the UK and prepares consolidated financial statements in GBP. It has an American subsidiary, Company US, whose functional currency is the US dollar and is included in the consolidated financial statements of Company UK. Company US has forecast sales in GBP that are highly probable. Company US wishes to eliminate the US dollar/GBP foreign currency risk from the highly probable GBP sales and requests its parent, Company UK, to undertake an external hedging transaction.

Case 1: Company UK transacts a forward contract to sell GBP and buy US dollars to hedge Company US's foreign currency risk from the change in GBP relative to the US dollar. In Company UK's consolidated financial statements it would be possible to designate the forward contract as a hedge of Company US's GBP forecast sales. This is because both the hedged item and the hedging instrument impact consolidated profit or loss with respect to US dollar/GBP foreign currency risk.

Case 2: Company UK transacts a GBP loan as a hedging instrument for Company US's highly probable GBP forecast sales. In Company UK's consolidated financial statements it would not be possible to designate the GBP loan as a hedge of Company US's GBP forecast sales as there is no impact on consolidated profit or loss from the GBP loan with respect to US dollar/GBP foreign currency risk. This is because foreign currency risk does not arise in an entity from monetary items denominated in the same currency as its functional currency.

The above analysis only considers hedge accounting in Company UK's consolidated financial statements. Unless Company UK also transacted an internal hedging contract with Company US no protection would be provided against the US dollar/GBP foreign currency risk from the highly probable GBP sales in Company UK's standalone financial statements.

5 Types of hedging relationships

There are three types of hedging relationship defined in IFRS 9: [IFRS 9.6.5.2]

Extract from IFRS 9

6.5.2 There are three types of hedging relationships:

- (a) fair value hedge: a hedge of the exposure to changes in fair value of a recognised asset or liability or an unrecognised firm commitment, or a component of any such item, that is attributable to a particular risk and could affect profit or loss.
- (b) cash flow hedge: a hedge of the exposure to variability in cash flows that is attributable to a particular risk associated with all, or a component of, a recognised asset or liability (such as all or some future interest payments on variable-rate debt) or a highly probable forecast transaction, and could affect profit or loss.
- (c) hedge of a net investment in a foreign operation as defined in IAS 21.

[IFRS 9.6.5.2].

Each of these definitions are considered further in the remainder of this section (fair value hedges in section 5.1, cash flow hedges in section 5.2, and hedges of a net investment in a foreign operation in section 5.3).

5.1 Fair value hedges

An example of a fair value hedge is a hedge of the exposure to changes in the fair value of a fixed rate debt instrument (not measured at fair value through profit or loss) as a result of changes in interest rates - if interest rates increase, the fair value of the debt decreases and *vice versa*. Such a hedge could be entered into either by the issuer or by the holder. [IFRS 9.B6.5.1].

On the face of it, if a fixed rate loan that is measured at amortised cost or fair value through OCI and is held until it matures (as is the case for many such loans), changes in the fair value of the loan would not affect profit or loss. However, the fact that the loan could be sold, in which case fair value changes would affect profit or loss means that such a hedge relationship meets the requirement, set out in section 5 above, that variability in the hedged risk could affect profit or loss. The same would be true of a fixed rate borrowing even if settlement before maturity is very unlikely.

A variable rate debt could be the hedged item in a fair value hedge in certain circumstances. For example, the fair value of such an instrument will change if the issuer's credit risk changes. Accordingly, variable rate debt could be designated in a hedge of all changes in its fair value. There might also be changes in its fair value relating to movements in the market rate in the periods between which the variable rate is reset. For example, if a debt instrument provides for annual interest payments reset to the market rate each year, a portion of the debt instrument has an exposure to changes in fair value during the year. [IAS 39.F.3.5].

In June 2019, within the context of a fair value hedge of foreign currency risk of a non-financial asset held for consumption, the IFRS IC discussed the requirement that to designate a hedged risk, an entity must conclude that the hedged risk 'could affect profit or loss'.¹⁶

Depending on the particular facts and circumstances, a non-financial asset might be priced-and its fair value determined-only in one currency at a global level and that currency is not the entity's functional currency. The translated fair value of such a non-financial asset would change as a result of changes in the applicable exchange rate in a given period, even if the fair value (determined in the foreign currency) were to remain constant. The Committee therefore observed that in such circumstances an entity is exposed to foreign currency risk. IFRS 9 does not require changes in fair value to be expected to affect profit or loss but, rather, that those changes could affect profit or loss. [IFRS 9.6.5.2(a)]. The IFRS IC observed that changes in fair value of a non-financial asset held for consumption could affect profit or loss if, for example, the entity were to sell the asset before the end of the asset's economic life.

¹⁶ [IFRIC Update](#), June 2019, available on the IFRS Foundation's website.

Consequently, the IFRS IC concluded that, depending on the particular facts and circumstances, it is possible for an entity to have exposure to foreign currency risk on a non-financial asset held for consumption that could affect profit or loss. However, in order to achieve fair value hedge accounting for such a risk, the IFRS IC also noted the importance of:

- Consistency of any hedge designation with the entity's risk management objective and strategy for managing its exposure (see section 6.2.1 below)
- And
- The foreign currency risk to be a separately identifiable and reliably measurable risk component of the non-financial asset (see section 2.6.8 above)

In addition to the conclusion of the IFRS IC, the Implementation Guidance of IAS 39 also provides some assistance in understanding how the hedged risk could impact profit or loss, by way of an example. This guidance is given here and remains relevant under IFRS 9. The exposure to changes in the price of inventories that are carried at the lower of cost and net realisable value could also be the subject of a fair value hedge because their fair value will affect profit or loss when they are sold or written down. For example, a copper forward could be used as the hedging instrument in a hedge of the copper price associated with copper inventory. [IAS 39.F.3.6].

Extract from IFRS 9

B6.3.2 An equity method investment cannot be a hedged item in a fair value hedge. This is because the equity method recognises in profit or loss the investor's share of the investee's profit or loss, instead of changes in the investment's fair value. For a similar reason, an investment in a consolidated subsidiary cannot be a hedged item in a fair value hedge. This is because consolidation recognises in profit or loss the subsidiary's profit or loss, instead of changes in the investment's fair value. A hedge of a net investment in a foreign operation is different because it is a hedge of the foreign currency exposure, not a fair value hedge of the change in the value of the investment.

[IFRS 9.B6.3.2].

How we see it

Assuming an investment in a subsidiary is held at cost or fair value through other comprehensive income, it would in our view be possible to designate the foreign currency risk in the carrying value of a foreign currency denominated investment in the parent entity's separate financial statements (see section 7.3.6 below). Further, we believe it would be possible to hedge the change in the entire fair value of the investment even if the fair value is not reflected in the parent entity's separate financial statements. This hedge relationship would most likely be treated as a fair value hedge and would require an adjustment to be made to the carrying value of the investment.

The ongoing accounting for fair value hedges is described in section 7.1 below.

5.1.1 Hedges of firm commitments

A hedge of a firm commitment (e.g., a hedge of the change in fuel price relating to an unrecognised contractual commitment by an electricity utility to purchase fuel at a fixed price) is considered a hedge of an exposure to a change in fair value. Accordingly, such a hedge is a fair value hedge. However, a hedge of the foreign currency risk of a firm commitment may be accounted for as either a fair value hedge or a cash flow hedge (this is discussed further in section 5.2.2 below). [IFRS 9.B6.5.3].

5.1.2 Hedges of foreign currency monetary items

A foreign currency monetary asset or liability that is hedged using a forward exchange contract could be treated as a fair value hedge because its fair value will change as foreign currency rates change (see sections 7.1 and 7.2.3 below). Alternatively, it could be treated as a cash flow hedge because changes in exchange rates will affect the amount of cash required to settle the item (as measured by reference to the entity's functional currency) (see section 7.2 below).

5.2 Cash flow hedges

A cash flow hedge is a hedge of exposure to variability in cash flow attributable to a particular risk associated with an eligible hedged item that could affect profit or loss. The purpose of a cash flow hedge is to defer the gain or loss on the hedging instrument to a period or periods in which the hedged expected future cash flows affect profit or loss. An example of a cash flow hedge is the use of an interest rate swap to change floating rate debt (whether measured at amortised cost or fair value (see section 2.6.2 above)) to fixed rate debt, i.e., a hedge of a future transaction where the future cash flows being hedged are the future interest payments. [IFRS 9.6.5.2(b), IFRS 9.B6.5.2].

As noted in section 5.1 above, a hedge of the exposure to changes in the fair value of a fixed rate debt instrument as a result of changes in interest rates could be treated as a fair value hedge. This could not be a cash flow hedge because changes in interest rates will not affect the cash flows on the hedged item, only its fair value.

It is also noted in section 7.1.2 below that a copper forward, say, could be used in a fair value hedge of copper inventory. Alternatively, the same hedging instrument could qualify as a cash flow hedge of the highly probable future sale of the inventory. [IAS 39.F.3.6].

The following Illustration based on an example from the IAS 39 Implementation Guidance explains how a company might lock in current interest rates by way of a cash flow hedge of the anticipated issuance of fixed rate debt.

Illustration 5-1: Hedge of anticipated issuance of fixed rate debt

Company R periodically issues new bonds to refinance maturing bonds, provide working capital, and for various other purposes. When R decides it will be issuing bonds, it sometimes hedges the risk of changes in long-term interest rates to the date the bonds are issued. If long-term interest rates go up (down), the bond will be issued either at a higher (lower) rate, with a higher (smaller) discount or with a smaller (higher) premium than was originally expected. The higher (lower) rate being paid or decrease (increase) in proceeds is normally offset by the gain (loss) on the hedge.

In August 20X2 R decides it will issue GBP2m seven-year bonds in January 20X3. Historical correlation studies suggest that a seven-year UK treasury bond adequately correlates to the bonds R expects to issue, assuming a hedge ratio of 0.93 future contracts to one debt unit (see section 6.4.3 below). Therefore, it hedges the anticipated issuance of the bonds by selling ('shorting') GBP1.86m worth of futures on seven-year treasury bonds.

From August 20X2 to January 20X3 interest rates increase and the short futures positions are closed on the date the bonds are issued. This results in a GBP120,000 gain, which offsets the increased interest payments on the bonds and, therefore, will affect profit or loss over the life of the bonds. The hedge could qualify as a cash flow hedge of the interest rate risk on the forecast debt issuance (assuming all other conditions for hedge accounting are met) (see section 7.2 below for discussion on cash flow hedge accounting entries if hedge accounting is applied). [IAS 39.F.2.2].

Similarly, the forecast reinvestment of interest cash flows from a fixed rate asset can be the subject of a cash flow hedge using, say, a forward rate agreement to lock in the interest rate that will be received on that reinvestment.

Another common cash flow hedging strategy is to eliminate variability in cash flows attributable to highly probable forecast sales or purchases (see sections 2.1 and 2.6.1 above).

Illustration 5-2: Hedge of highly probable forecast purchases

Company P regularly purchases coffee for use within its restaurant business. Company P has a risk management strategy to eliminate variability in purchases of ingredients over a rolling 12 month period. Company P determines that it has highly probable forecast purchases of 37,500 pounds of coffee every 3 months. Accordingly, Company P purchases four NYMEX coffee futures, each for 37,500 pounds of coffee, for settlement in March, July, September and December.

As Company P purchases the coffee each quarter, the purchase price will be determined based on the prevailing coffee price. By purchasing the coffee futures, any increase (or decrease) in the price Company P paid for the coffee will be offset to some extent by a change in price of the relevant coffee futures purchased for that quarter. The variation in price of the actual purchases will affect profit or loss, so the hedge of variation in the coffee price could be an eligible hedge accounting relationship under IFRS 9. The extent to which 'offset' does arise in profit or loss depends on the relationship between Company P's actual purchase price of coffee and the underlying coffee price in the futures contract (see section 7.4 below).

The ongoing accounting for cash flow hedges is described in section 7.2 below.

5.2.1 All-in-one hedges

The Implementation Guidance of IAS 39 made specific reference to an 'all in one hedge'. Although none of the IAS 39 Implementation Guidance on hedge accounting was carried forward into IFRS 9, much of it remains relevant under IFRS 9 (see section 1.3 above). [IFRS 9.BC6.94, IFRS 9.BC6.95]. Accordingly, the IAS 39 guidance on an 'all in one hedge' is discussed below with respect to application within IFRS 9.

There are situations where an instrument that is accounted for as a derivative is expected to be settled gross by delivery of the underlying asset in exchange for the payment of a fixed price. The IAS 39 Implementation Guidance states that such an instrument can be designated as the hedging instrument in a cash flow hedge of the variability of the consideration to be paid or received in the future transaction that will occur on gross settlement of the derivative contract itself. It is explained that this is acceptable because there would be an exposure to variability in the purchase or sale price without the derivative. It is important to note that, in order to qualify for a hedge of a highly probable forecast transaction, the hedging entity must have the intention (and the ability) to gross settle the derivative. For example, consider an entity that enters into a fixed price contract to sell a commodity and that contract is accounted for as a derivative under IFRS 9 (see Chapter 41). This might be because the entity has a practice of settling such contracts net in cash or of taking delivery of the underlying and selling it within a short period after delivery for the purpose of generating a profit from short-term fluctuations in price or dealer's margin. In this case, the fixed price contract may be designated as a cash flow hedge of the variability of the consideration to be received on the sale of the asset (a future transaction) even though the fixed price contract is the contract under which the asset will be sold. [IAS 39.F.2.5].

Similarly, an entity may enter into a forward contract to purchase a debt instrument that will be settled by delivery of the debt instrument, but the forward contract is a derivative (some restrictions apply if the debt instrument is to be classified at fair value through profit or loss (see section 2.6.2 above)). This will be the case if its term exceeds the regular way delivery period in the marketplace (see Chapter 45). In this case the forward may be designated as a cash flow hedge of the variability of the consideration to be paid to acquire the debt instrument (a future transaction), even though the derivative is the contract under which the debt instrument will be acquired. [IAS 39.F.2.5].

Conversely, it is not possible to apply the all-in-one hedge strategy to a forward contract to purchase an equity instrument that will be settled by delivery of the equity instrument, where the forward contract is a derivative. This is because cash flow hedging of a forecast purchase of equity instrument is precluded, since any gain or loss on the hedging instrument that would be deferred could not be appropriately reclassified to profit (see section 2.6.2 above).

5.2.2 Hedges of foreign currency firm commitments

A hedge of the foreign currency risk of a firm commitment could be accounted for as a cash flow hedge or a fair value hedge (see section 5.1.1 above). [IFRS 9.B6.5.3]. This is because foreign currency risk affects both the cash flows and the fair value of the hedged item. Accordingly, a foreign currency cash flow hedge of a forecast transaction need not be redesignated as a fair value hedge when the forecast transaction becomes a firm commitment.

5.2.3 Hedges of foreign currency monetary items

A foreign currency monetary asset or liability that is hedged using a forward exchange contract could be treated as a fair value hedge because its fair value will change as foreign currency rates change. Alternatively, it could be treated as a cash flow hedge because changes in exchange rates will affect the amount of cash required to settle the item (as measured by reference to the entity's functional currency). There are some potential advantages to treating the hedge of a foreign currency monetary asset or liability using a forward exchange contract as a cash flow hedge (see section 7.2.3 below).

5.3 Hedges of net investments in foreign operations

Many reporting entities have investments in foreign operations which could be subsidiaries, associates, joint ventures or branches. As set out in Chapter 16, IAS 21 requires an entity to determine the functional currency of each of its foreign operations as the currency of the primary economic environment of that operation. When translating the results and financial position of its foreign operation into a presentation currency, it is required to recognise foreign exchange differences in other comprehensive income until disposal of the foreign operation. [IFRIC 16.1].

From the perspective of an investor (e.g., a parent) it is clear that an investment in a foreign operation is likely to give rise to a degree of foreign currency exchange rate risk and an entity with many foreign operations could be exposed to a number of foreign currency risks. [IFRIC 16.4]. Whilst equity method investments and investments in consolidated subsidiaries cannot be hedged items in a fair value hedge because changes in the investments' fair value are not recognised in profit or loss (see section 5.1 above), they could be designated in a net investment hedge relationship. A hedge of a net investment in a foreign operation is said to be different because it is a hedge of the foreign currency exposure, not a fair value hedge of the change in the value of the investment. [IFRS 9.B6.3.2].

Conceptually, net investment hedging is somewhat unsatisfactory, as it mixes foreign currency translation risk (largely an accounting exposure) with transactional risk (much more an economic exposure). IFRIC 16 *Hedges of a Net Investment in a Foreign Operation* addresses the question of what does and does not constitute a valid hedging relationship, a topic on which IFRS 9 provides very little guidance.

IFRIC 16 applies to any entity that hedges the foreign currency risk arising from its net investments in foreign operations and wishes to qualify for hedge accounting in accordance with IFRS 9. [IFRIC 16.7]. It only applies to those hedges and should not be applied by analogy to other types of hedge accounting. [IFRIC 16.8]. For the avoidance of doubt, IFRIC 16 explains that such a hedge can be applied only when the net assets of that foreign operation are included in the financial statements. This will be the case for consolidated financial statements, financial statements in which investments such as associates or joint ventures are accounted for using the equity method or those that include a branch or a joint operation (as defined in IFRS 11 *Joint Arrangements*). [IFRIC 16.2]. For convenience, IFRIC 16 refers to such an entity as a parent entity and to the financial statements in which the net assets of foreign operations are included as consolidated financial statements and this section follows this convention. [IFRIC 16.7].

Investments in foreign operations could be held directly by a parent entity or indirectly by its subsidiary or subsidiaries (see section 5.3.1 below). [IFRIC 16.12].

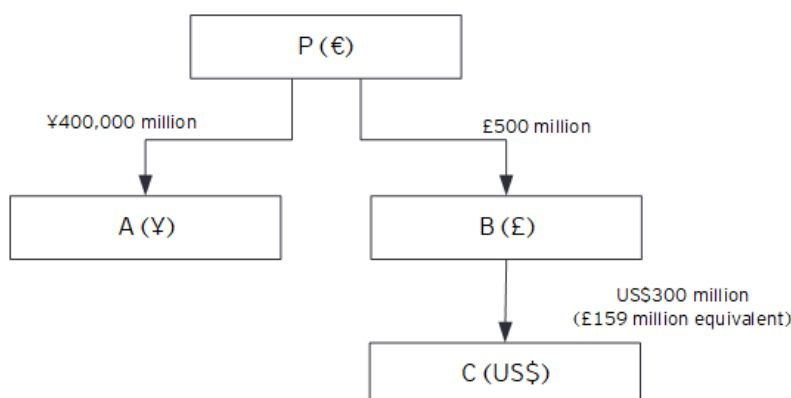

The requirements of IFRIC 16 are discussed in more detail in sections 5.3.1 to 5.3.3 below and, in the case of accounting for such a hedge, in section 7.3 below.

5.3.1 Nature of the hedged risk

Perhaps the most important decision made by the IFRS IC was that hedge accounting may be applied only to the foreign exchange differences arising between the functional currency of the foreign operation and the parent entity's functional currency. [IFRIC 16.10]. However, the hedged risk may be designated as the foreign currency exposure arising between the functional currency of the foreign operation and the functional currency of any parent entity (the immediate, intermediate or ultimate parent entity) of that foreign operation. The fact that the net investment is held through an intermediate parent does not affect the nature of the economic risk arising from the foreign currency exposure to the ultimate parent entity. [IFRIC 16.12]. This principle is shown in the following Illustration.

Illustration 5-3: Nature of the hedged risk in a net investment hedge

Company P is the ultimate parent entity of a group and presents its consolidated financial statements in its functional currency of euro. It has two direct wholly owned subsidiaries, Company A whose functional currency is Japanese yen and Company B whose functional currency is sterling. B has a wholly owned subsidiary, Company C, whose functional currency is US dollars. P's net investment in A is ¥400,000 million. P's net investment in B is £500 million including the equivalent of £159 million representing B's net investment in C of US\$300 million. P also has external borrowings of US\$300 million. This corporate structure is illustrated as follows:

P, in its consolidated financial statements, could hedge its net investment in each of A, B and C for the foreign exchange risk between their functional currencies (Japanese yen, sterling and US dollars respectively) and euro. P could, as an alternative to hedging P's investment in C, hedge the foreign exchange risk between the functional currencies of B (sterling) and C (US dollars).

In its consolidated financial statements, B could hedge its net investment in C for the foreign exchange risk between C's functional currency (US dollars) and its own (sterling). [IFRIC 16.AG1, IFRIC 16.AG2, IFRIC 16.AG3].

Where a non-derivative instrument is used as the hedging instrument, the designated risk must be the spot foreign exchange risk; if the hedging instruments were forward contracts (or other foreign currency derivatives), the forward or the spot foreign exchange risk could be designated as the hedged risk (see sections 7.3.3 and 7.3.4 below). [IFRIC 16.AG2].

5.3.2 Amount of the hedged item for which a hedging relationship could be designated

In a hedge of the foreign currency risks arising from a net investment in a foreign operation, the hedged item can be an amount of net assets equal to or less than the carrying amount of the net assets of the foreign operation in the consolidated financial statements of the parent entity. [IFRIC 16.11].

How we see it

Although the hedged item is described throughout IFRIC 16 with reference to the net assets, there is nothing within the guidance to suggest that a hedge of negative net assets would be precluded.

Illustration 5-4: Amount of hedged item in a net investment hedge

The facts are as in Illustration 5-3 above. If P wished to hedge the foreign exchange risk from its net investment in C, it could use its external borrowing of US\$300 million as a hedging instrument and the hedged item could be an amount of net assets equal to or less than the US\$300 million carrying amount of C in P's consolidated financial statements. [IFRIC 16.AG4].

The carrying amount of the net investment takes account of monetary items receivable from or payable to a foreign operation for which settlement is neither planned nor likely to occur in the future. These balances are considered to be, in substance, part of the reporting entity's net investment in the foreign operation. [IAS 21.15]. A loan made to the foreign operation, for which settlement is neither planned nor likely to occur in the future, will increase the amount that can be hedged; if a loan is made by the foreign operation, the amount that can be hedged will be reduced. [IFRIC 16.AG14].

In many cases the full economic value of a net investment will not be recognised in the financial statements. The most common reason will be the existence of, say, goodwill or intangible assets that are either not recognised or measured at an amount below their current value (see Chapter 10 and Chapter 18). In these situations, if an investor hedges the entire economic value of its net investment, it will not be able to obtain hedge accounting for the proportion of the hedging instrument that exceeds the recognised net assets.

A single hedging instrument can hedge the same designated risk only once. Consequently, in Illustration 5-3 and Illustration 5-4 above, P could not in its consolidated financial statements designate its external borrowing in a hedge of both the €/US\$ spot foreign exchange risk and the £/US\$ spot foreign exchange risk in respect of its net investment in C. [IFRIC 16.AG6].

The carrying amount of the net assets of a foreign operation that may be designated as the hedged item in the consolidated financial statements of a parent depends on whether any lower level parent of the foreign operation has applied hedge accounting for all or part of the net assets of that foreign operation and whether that accounting has been maintained in the parent's consolidated financial statements. [IFRIC 16.11]. An exposure to foreign currency risk arising from a net investment in a foreign operation may qualify for hedge accounting only once in the consolidated financial statements. Therefore, if the same net assets of a foreign operation are hedged by more than one parent entity within the group (for example, both a direct and an indirect parent entity) for the same risk, only one hedging relationship will qualify for hedge accounting in the consolidated financial statements of the ultimate parent. [IFRIC 16.13]. This is shown in the following Illustration.

Illustration 5-5: Amount of hedged item in a net investment hedge (different hedged risks)

The facts are the same as in Illustration 5-3 and Illustration 5-4 above except that P's net assets include £500 million external borrowings in addition to the US\$300 million of external borrowings. If P wished to hedge the foreign exchange risk in relation to its net investments in B and C, the designations it could make in its consolidated financial statements include the following: [IFRIC 16.AG10]

- US\$300 million of the US dollar borrowings designated as a hedge of the net investment in C with the risk being the spot foreign exchange exposure (€/US\$) between P and C and up to £341 million of the sterling borrowings designated as a hedge of the net investment in B with the risk being the spot foreign exchange exposure (€/£) between P and B.
- Or
- US\$300 million of the US dollar borrowings as a hedge of the net investment in C with the risk being the spot foreign exchange exposure (£/US\$) between B and C and up to £500 million of the sterling borrowings designated as a hedge of the net investment in B with the risk being the spot foreign exchange exposure (£/£) between P and B.

The €/US\$ risk from P's net investment in C is a different risk from the €/£ risk from P's net investment in B. However, in the first case described above, P would have already fully hedged the €/US\$ risk from its net investment in C and if P also designated its £500 million of borrowings as a hedge of its net investment in B, £159 million of that net investment, representing the sterling equivalent of its US dollar net investment in C, would be hedged twice for £/€ risk in P's consolidated financial statements. [IFRIC 16.AG11]. The £341 million that could be designated is just £500 million less £159 million.

In the second case described above, because the designation of the US\$/£ risk between B and C does not include the £/€ risk, P is also able to designate up to £500 million of its net investment in B with the risk being the spot foreign currency exposure (£/€) between P and B. [IFRIC 16.AG12].

A hedging relationship designated by one parent entity in its consolidated financial statements need not be maintained by another higher level parent entity. However, if it is not maintained by the higher level parent entity, the hedge accounting applied by the lower level parent must be reversed before the higher level parent's hedge accounting is recognised. [IFRIC 16.13]. This is shown in the following Illustration.

Illustration 5-6: Hedge accounting applied by intermediate parent

The facts are the same as in Illustration 5-3 and Illustration 5-4 above, except that P's net assets include £500 million of external borrowings and B's net assets of £341 million include US\$300 million of external borrowings which it designates as a hedge of the £/US\$ risk of its net investment in C in its own consolidated financial statements.

P could maintain B's designation of that hedging instrument as a hedge of its net investment in C for the £/US\$ risk and P could designate its £500 million external borrowings as a hedge of its entire net investment in B. The first hedge, designated by B, would be assessed by reference to B's functional currency (sterling) and the second hedge, designated by P, would be assessed by reference to P's functional currency (euro). In this case, only the £/US\$ risk from P's net investment in C has been hedged in its consolidated financial statements by B's US dollar borrowings, not the entire €/US\$ risk. Therefore, the entire €/£ risk from P's net investment in B may be hedged in P's consolidated financial statements. [IFRIC 16.AG13].

Alternatively, P could reverse the hedging relationship designated by B. In this case, it could designate B's US\$300 million external borrowing as a hedge of its net investment in C for the €/US\$ risk and designate £341 million of its borrowings as a hedge of part of the net investment in B. In this case the effectiveness of both hedges would be computed by reference to P's functional currency (euro). Consequently, both the US\$/£ and £/€ changes in value of B's US\$300 million borrowing would be included in P's foreign currency translation reserve. Because P has already fully hedged the €/US\$ risk from its net investment in C, it could hedge only up to £341 million for the €/GBP risk of its net investment in B. [IFRIC 16.AG15].

5.3.3 Where the hedging instrument can be held

IFRIC 16 also states that the hedging instrument(s) may be held by any entity or entities within the group, including the foreign operation being hedged, provided the designation, documentation and qualification criteria of IFRS 9 are satisfied. However, this could only be the case for an instrument held by the foreign operation if the remeasurement of the hedging instrument with respect to the functional currency of the parent has an impact on consolidated profit or loss (e.g., in the case of a derivative hedging instrument). The hedging strategy of the group should be clearly documented because of the possibility of different designations at different levels of the group (see section 5.3.2 above). [IFRIC 16.14, IFRIC 16.BC24A, IFRIC 16.BC24B, IFRIC 16.BC24C, IFRIC 16.BC24D]. This is illustrated by Illustration 7-7 in section 7.3.1.

Where the entity holding the hedging instrument has a functional currency that is not the same as the parent by which the hedged risk is defined, this could result in some of the foreign exchange difference on the hedging instrument remaining in profit or loss - this is discussed further in section 7.3.1 below.

Clearly the reporting entity (which, in the case of consolidated financial statements, includes any subsidiary consolidated by the parent) must be a party to the hedging instrument. In Illustration 5-4 and Illustration 5-5 above, therefore, B could not apply hedge accounting in its consolidated financial statements in respect of a hedge involving the US\$300 million borrowing issued by P because the hedging instrument is held outside of the group headed by B. [IFRIC 16.AG6].

6 Qualifying criteria

6.1 General requirements

In order to qualify for hedge accounting as set out in section 7 below, all of the following criteria must be met:

- The hedging relationship consists only of eligible hedged items and eligible hedging instruments (see sections 2 and 3 above).
- At inception of the hedging relationship, there is formal designation and documentation of the hedging relationship and entity's risk management objective and strategy for undertaking the hedge (see section 6.2 below). That documentation shall include an identification of the hedging instrument, the hedged item, the nature of the risk being hedged and how the entity will assess the effectiveness requirements (including its analysis of the sources of hedge ineffectiveness and how it determines the hedge ratio (see section 6.3 below)).

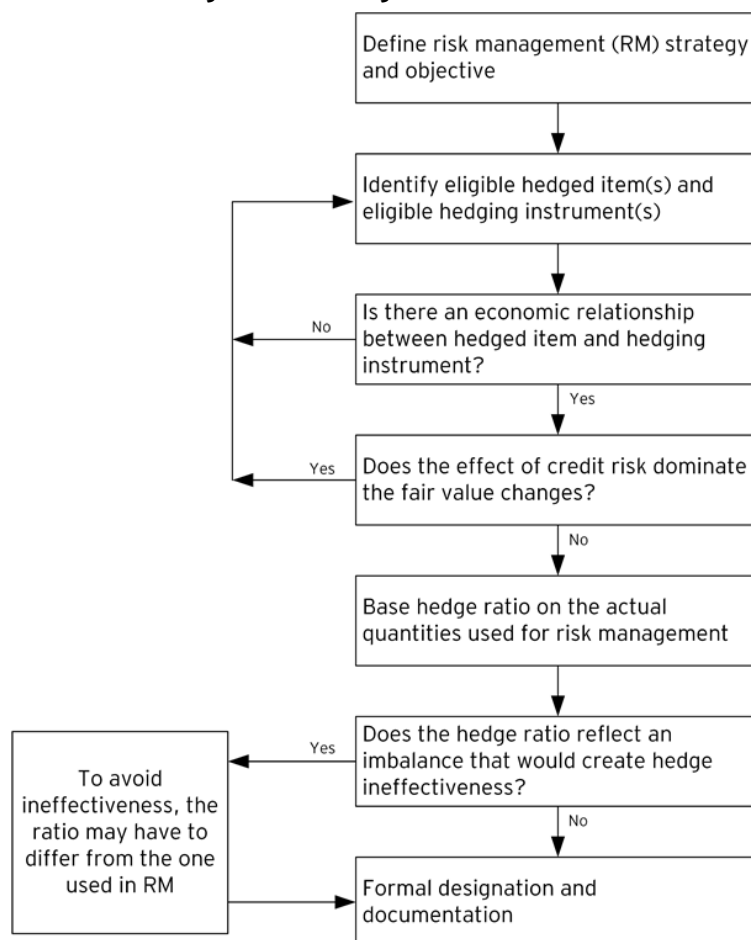

And

- The hedging relationship meets all the following hedge effectiveness requirements (see section 6.4 below):
 - There is an economic relationship between the hedged item and the hedging instrument (see section 6.4.1 below).
 - The effect of credit risk does not dominate the value changes that result from that economic relationship (see section 6.4.2 below).
 And
 - The hedge ratio of the hedging relationship is the same as that resulting from the quantity of the hedged item that the entity actually hedges and the quantity of the hedging instrument that the entity actually uses to hedge that quantity of the hedged item. However, that designation shall not reflect an imbalance between the weightings of the hedged item and the hedging instrument that would create hedge ineffectiveness (irrespective of whether recognised or not) that could result in an accounting outcome that would be inconsistent with the purpose of hedge accounting. The second part of this requirement is an anti-abuse clause that is explained in more detail in section 6.4.3 below. *[IFRS 9.6.4.1]*.

It is also a requirement that the designated hedge relationship is one of the three permitted types of hedges: a fair value hedge, a cash flow hedge, or a hedge of a net investment in a foreign operation (see sections 5.1, 5.2 and 5.3 respectively above). *[IFRS 9.6.5.2]*.

The required steps for designating a hedging relationship can be summarised in a flow chart as follows:

Figure 6-1: How to achieve hedge accounting

The initial effectiveness requirements also form the basis for the subsequent effectiveness assessment in order to continue to achieve hedge accounting, which is discussed in section 8 below.

6.2 Risk management strategy versus risk management objective

Linking hedge accounting with an entity's risk management activities requires an understanding of what those risk management activities are. IFRS 9 distinguishes between the risk management strategy and the risk management objective. One of the qualifying criteria for hedge accounting is that the risk management objective and strategy are documented. [IFRS 9.6.4.1(b)].

The risk management strategy is established at the highest level of an entity and identifies the risks to which the entity is exposed, and whether and how the risk management activities will address those risks. For example, a risk management strategy could identify changes in interest rates of loans as a risk and define a specific target range for the fixed to floating rate ratio for those loans. The strategy is typically maintained for a relatively long period of time. However, it could include some flexibility to react to changes in circumstances. [IFRS 9.B6.5.24].

IFRS 9 refers to the risk management strategy as normally being set out in "a general document that is cascaded down through an entity through policies containing more specific guidelines." [IFRS 9.B6.5.24].

Presumably, the documentation of the risk management strategy does not need to be in a separate formal written document in all circumstances. Small and medium-sized entities with limited risk management activities that use financial instruments might not have a formal written document outlining their overall risk management strategy that they have in place. In some instances, individuals within the entity could be formally empowered to decide on what is done for risk management purposes. In such situations entities do not have the benefit of being able to incorporate the risk management strategy in their hedge documentation by reference to a formal policy document, but instead have to include a description of their risk management strategy directly in their hedge documentation.

Consequently, a more informal risk management strategy must be both reflected in the disclosures and 'compensated' by a more detailed documentation of the hedging relationships.

The risk management strategy is an important cornerstone of the hedge accounting requirements in IFRS 9. Consequently, the Board added specific disclosure requirements that are expected to allow users of the financial statements to understand the risk management activities of an entity and how they affect the financial statements (see Chapter 50). [IFRS 7.21A(a)]. The disclosure requirements for the risk management strategy apply irrespective of whether or not an entity uses a formal written policy document as part of its risk management activities.

The risk management objective, on the contrary, is set at the level of an individual hedging relationship. It defines how a particular hedging instrument is designated to hedge a particular hedged item, and how that hedging instrument is used to achieve the risk management strategy. For example, this would define how a specific interest rate swap is used to 'convert' a specific fixed rate liability into a floating rate liability. Hence, a risk management strategy can involve many different hedging relationships whose risk management objective relates to executing that overall risk management strategy. [IFRS 9.B6.5.24].

Illustration 6-1: Risk management strategies with related risk management objectives

The table below shows three examples of a risk management strategy with a related risk management objective.

Risk management strategy	Risk management objective
Maintain 40% of financial debt at floating interest rate	Designate an interest rate swap as a fair value hedge of a GBP100m fixed rate liability
Hedge foreign currency risk of up to 70% of forecast sales in USD up to 12 months in advance	In January 20X2 designate a foreign currency forward contract to hedge the foreign currency risk of the first USD100 sales in June 20X2
Manage the duration risk from a portfolio of fixed rate loans within particular risk limits.	Designate a group of derivatives as hedging the interest rate risk in the portfolio for 3 months or until the duration of the designated hedged items and hedging instruments are no longer sufficiently matched, if earlier.

It is essential to understand the difference between the risk management strategy and the risk management objective. In particular, even if the risk management strategy remains the same, a change in a risk management objective will affect the entity's ability to continue applying hedge accounting as documented (see section 8.3.3 below). Furthermore, voluntary discontinuation of a hedging relationship without a respective change in the risk management objective is not allowed. This is described in section 8.3 below.

The Implementation Guidance within IAS 39 contained some guidance that risk reduction on an entity-wide basis was not a condition for hedge accounting. Within the context of the risk management objective, that guidance remains relevant under IFRS 9. [IAS 39.F.2.6]. However, as the risk management strategy is established at the highest level of an entity, it would seem contrary to the objective of the hedge accounting if the strategy was to increase entity-wide risk. [IFRS 9.6.1.1].

6.2.1 Designating 'proxy hedges'

The objective of the standard is "to represent, in the financial statements, the effect of an entity's risk management activities". [IFRS 9.6.1.1]. However, this does not mean that an entity can only designate hedging relationships that exactly mirror its risk management activities. The Basis for Conclusions notes that, in some circumstances, the designation for hedge accounting purposes is inevitably not the same as an entity's risk management view of its hedging, but that the designation reflects risk management in that it relates to the same type of risk that is being managed and the instruments used for this purpose. The IASB refer to this situation as 'proxy hedging' (i.e., designations that do not exactly represent the actual risk management). In redeliberating the September 2012 draft standard, the Board decided that proxy hedging is permitted, provided the designation is directionally consistent with the actual risk management activities.¹⁷ Furthermore, where there is a choice of accounting hedge designation, there is no apparent requirement for an entity to select the designation that most closely matches the risk management view of hedging as long as the chosen approach is still directionally consistent with actual risk management. [IFRS 9.BC6.98, IFRS 9.BC6.99, IFRS 9.BC6.100].

17 [IASB Update](#), January 2013, available on the IFRS Foundation's website.

In June 2019, within the context of a fair value hedge of foreign currency risk of a non-financial asset held for consumption, the IFRS IC discussed the extent to which a designated hedge relationship must be consistent with an entity's risk management activities (see section 2.6.8 above).¹⁸

Paragraph 6.4.1(b) of IFRS 9 requires that, at the inception of a hedging relationship, "there is formal designation and documentation of the hedging relationship and the entity's risk management objective and strategy for undertaking the hedge". Accordingly, the IFRS IC observed that, in applying IFRS 9, an entity can apply hedge accounting only if it is consistent with the entity's risk management objective and strategy for managing its exposure. An entity therefore cannot apply hedge accounting solely on the basis that it identifies items in its statement of financial position that are measured differently but are subject to the same type of risk.

The IFRS IC observed that to the extent that an entity intends to consume a non-financial asset (rather than to sell it), changes in the fair value of the non-financial asset could be of limited significance to the entity. In such cases, an entity might not be economically managing or hedging risk exposures on the non-financial asset and, in that case, it cannot apply hedge accounting.

However, although the IFRS IC has reiterated the importance of consistency between designation of a hedge relationship and the entity's risk management objective and strategy, proxy hedging is still permitted, as long as the hedge designation is still directionally consistent with actual risk management. The examples below are common proxy hedging designations:

Illustration 6-2: Common proxy hedging designations

Net position cash flow hedging

IFRS 9 limits the designation of net positions in cash flow hedges to hedges of foreign currency risk (see section 2.5.3 above). However, in practice, entities often hedge other types of risk on a net cash flow basis. Such entities could still designate the net position as a gross designation. [IFRS 9.BC6.100(a)].

For example, an entity holds CU2m of variable rate loan assets and CU10m of variable rate borrowings. The treasurer is hedging the cash flow risk exposure on the net position of CU8m, by entering into a pay fixed/receive variable interest rate swap (IRS) with a nominal amount of CU8m. Rather than designate the net CU8m as the hedged item, the entity could designate the IRS in a hedge of variable rate interest payments on a portion of CU8m of its CU10m variable rate borrowing.

The same approach could be applied when hedging the net foreign currency risk from forecast purchases and sales.

Risk components

An entity that hedges on a risk component basis in accordance with its risk management view might not meet the criteria for designating the hedged item as a risk component (see section 2.2 above). This does not mean that the entity is prohibited from applying hedge accounting altogether. The entity could designate the item in its entirety as the hedged item and apply hedge accounting, if all the qualifying criteria are met. [IFRS 9.BC6.100(b)].

For example, in the case where the price of the hedged item is based on a benchmark rate plus a negative spread, it is not possible to identify a benchmark rate risk component in the hedged item (see section 2.4 above). However, it would be possible to designate the entire hedged item within a hedge relationship, if all the other criteria for hedge accounting were met.

Macro hedging strategies

Permitting proxy hedging is of particular relevance for banks wishing to apply macro cash flow hedging strategies (see section 10 below). Typically, banks manage the interest margin risk resulting from fixed-floating mismatches of financial assets and financial liabilities held at amortised cost on their banking books. Assume the assets are floating rate and the liabilities are fixed rate. The fixed-floating mismatches are offset by entering into receive fixed/pay variable interest rate swaps. Currently there is no hedge accounting model that perfectly accommodates such hedges of the interest margin. Consequently, banks are forced to use either fair value hedge accounting for the liabilities or cash flow hedge accounting for the assets, although the actual risk management activity is neither to hedge fair values nor cash flows, but to hedge the interest margin. Both cash flow hedge accounting and fair value hedge accounting would be directionally consistent with the risk management activity and so acceptable as proxy hedging designations. [IFRS 9.BC6.98].

¹⁸ [IFRIC Update](#), June 2019, available on the IFRS Foundation's website.

6.3 Documentation and designation

An entity may choose to designate a hedging relationship between a hedging instrument and a hedged item in order to achieve hedge accounting. [IFRS 9.6.1.2]. At inception of the hedging relationship the documentation supporting the hedge must include the identification of:

- The hedging relationship and entity's risk management objective and strategy for undertaking the hedge (see section 6.2 above)
 - The hedging instrument (see section 3 above)
 - The hedged item (see section 2 above)
 - The nature of the risk being hedge (see section 2.2 above)
- And
- How the entity will assess the effectiveness requirements (including its analysis of the sources of hedge ineffectiveness and how it determines the hedge ratio (see section 6.4 below)) [IFRS 9.6.4.1(b)]

All the criteria in section 6.1 above, including the documentation requirements, must be met in order to achieve hedge accounting. [IFRS 9.6.4.1]. Accordingly, hedge accounting can be applied only from the date all the necessary documentation is completed and designation of a hedge relationship takes effect prospectively from that date. In particular, hedge relationships cannot be designated retrospectively.

Illustration 6-3: Hedge documentation

In order to meet the above documentation requirements, the hedge documentation must include definitive information on the following, where relevant:

IFRS 9.6.4.1 requirement	Detailed documentation required
Risk management objective and strategy (see section 6.2 above)	<ul style="list-style-type: none"> ▪ Risk management strategy (could reference a formal policy document) ▪ Risk management objective (specific to the hedge relationship)
Hedging instrument	<ul style="list-style-type: none"> ▪ Specific identification of hedging instrument(s), including whether hedging instrument(s) might be replaced by substitute hedging instruments (see section 8.3 below) ▪ Specified proportion (see section 3.6 above) ▪ Exclusion of time value, forward element or foreign currency basis (see sections 3.6.4 and 3.6.5 above) ▪ Whether part of a rollover strategy (see section 7.7 below) ▪ Whether part of a dynamic strategy (see section 6.3.2 below)
Hedged item	<ul style="list-style-type: none"> ▪ Identification of hedged item(s) with sufficient specificity to determine whether/when the hedged item has occurred (see sections 6.3.3 and 8.3.4 below) ▪ Specified proportion or layer (see section 2.3 above) ▪ Specified risk component (see section 2.2 above) ▪ Which contractual cash flows (if not all) (see section 2.1 above) ▪ Timing of and rationale for forecast transactions being highly probable (see section 2.6.1 above)
Risk being hedged	<ul style="list-style-type: none"> ▪ Hedge type (e.g., fair value, cash flow or net investment hedge) (see section 5 above) ▪ Specific identification of hedged risk ▪ Designation of a one side risk (see section 2.1 above)
Approach to effectiveness assessment (see section 6.4 below)	<ul style="list-style-type: none"> ▪ Rationale for existence of an economic relationship ▪ Hedge ratio and how determined ▪ The effects of credit risk and how determined ▪ Method for assessing the effectiveness qualification criteria ▪ Sources of hedge ineffectiveness ▪ Frequency of assessment
Date of designation	<ul style="list-style-type: none"> ▪ Date of designation ▪ Approval signature

Hedge effectiveness is the extent to which changes in the fair value or the cash flows of the hedging instrument offset changes in the fair value or the cash flows of the hedged item. When the hedged item is a risk component, the relevant change in fair value or cash flow of an item is the one that is attributable to the hedged risk (see section 2.2.1 above). [IFRS 9.B6.4.1].

If there are changes in circumstances that affect the hedge effectiveness, an entity may have to change the method for assessing whether a hedge relationship meets the hedge effectiveness requirements, in order to ensure that the relevant characteristics of the hedging relationship, including the sources of ineffectiveness are still captured. The hedge documentation must be updated to reflect any such changes. [IFRS 9.B6.4.2, IFRS 9.B6.4.17, IFRS 9.B6.4.19].

An entity can designate a new hedging relationship that involves the hedging instrument or hedged item of a previous hedging relationship, for which hedge accounting was (in part or in its entirety) discontinued (see section 2.4.1 above). This does not constitute a continuation but is a restart and requires redesignation. [IFRS 9.B6.5.28]. Hedge accounting will apply prospectively from redesignation, provided all other qualifying criteria are met. Even where the qualifying criteria are met, a hedge relationship in which an existing hedging instrument is designated, could result in higher levels of ineffectiveness (see section 7.4.3 below).

The need to meet the documentation requirements must not just be seen as a compliance exercise in order to achieve hedge accounting. The way in which the hedge relationship is documented can have significant implications on the way in which hedge accounting is applied, in particular in consideration of whether the hedge relationship must be discontinued (see section 8.3 below).

6.3.1 Business combinations

In a business combination accounted for using the purchase method of accounting, where the acquiree has designated hedging relationships, the question arises of whether the acquirer is:

- Permitted to continue to apply the hedge accounting model to hedge relationships designated previously by the acquiree, assuming it is consistent with the acquirer's strategies and policies
- Or
- Required to re-designate hedge relationships at the acquisition date¹⁹

IFRS 3 *Business Combinations* provides guidance that in order to obtain hedge accounting in their consolidated financial statements, acquirers are required to redesignate the acquiree's hedges. [IFRS 3.15, IFRS 3.16(b)]. Further, the acquirer must not recognise in its consolidated financial statements any amounts in equity in respect of any cash flow hedges of the acquiree relating to the period prior to acquisition (see section 7.2.4 below).

Redesignating the hedge relationships at the acquisition date means that if the hedging instrument has a fair value other than zero (see section 7.4.3 below), it is likely that ineffectiveness will be introduced in a hedge that might have been nearly 100% effective prior to the acquisition, particularly for cash flow hedges. To mitigate this, the acquirer could, subsequent to the combination, choose to settle the existing hedging instruments and replace them with similar 'on market' contracts with a zero fair value. Furthermore, this source of ineffectiveness could influence the chosen methodology used to demonstrate the existence of an economic relationship in order to qualify for hedge accounting in the acquirer's consolidated financial statements (see section 6.4.1 below). [IFRS 9.B6.4.15].

For business combinations under common control, for which IFRS 3 is not applicable, see further discussion in Chapter 9 and Chapter 11.

For discussion on the ability to achieve hedge accounting for management of risks arising from a proposed business combination, see section 2.6.4 above.

¹⁹ [INFORMATION FOR OBSERVERS](#), Board Meeting: 22 February 2007, London, Project: *Business Combinations II*, Subject: *Reassessments (Agenda Paper 2B)*, para. 25. Available on the IFRS Foundation's website.

6.3.2 Dynamic hedging strategies

A dynamic risk management strategy is one where the entity uses a dynamic process in which the exposure and the hedging instruments used to manage the exposure do not remain the same for long.

[IFRS 9.B6.5.24(b), IFRS 7.23C].

One such dynamic hedging strategy is where an entity assesses both the intrinsic value and time value of option contracts when hedging a risk exposure. Consider, as an example, a delta-neutral option hedging strategy (i.e., a strategy that is designed to create a net risk position (including the full option value) that is unlikely to be affected by small movements in the price of the underlying). In this situation it is helpful that there is no requirement to exclude the time value of hedging option contracts from the hedge relationship. IFRS 9 permits, but does not require, separation of the intrinsic and time value of an option contract and designation only of the intrinsic value as the hedging instrument (see section 3.6.4 above). [IFRS 9.6.2.4(a)]. Accordingly, for a delta-neutral option hedging strategy, it is possible to achieve hedge accounting without excluding the option time value, as long as the other qualifying criteria are met (see section 6.1 above).

Similarly, other dynamic hedging strategies under which the hedging instrument is constantly adjusted in line with the risk management strategy (perhaps in response to changes in the hedged items) in order to maintain a desired level of offset (e.g., to achieve a flat duration position, insensitive to changes in the fair value of the hedged item), could qualify for hedge accounting.

For a dynamic hedging strategy to qualify for hedge accounting, the documentation must specify how the hedge will be monitored and updated and how the effectiveness criteria will be assessed (see section 6.4 below). This would include documentation of the period over which the economic relationship assessment is considered, taking account of the dynamic nature of the hedge relationship (see section 6.4.1 below).

A key consideration is whether the periodic changes made as part of dynamic hedging strategy must be treated as:

- A discontinuation and redesignation of the hedge relationship. This will be the case if it is determined the risk management objective has changed (see section 6.2 above and section 8.3 below); or
- A rebalancing of the hedge relationship. This will be the case if it is determined that there is no change to the risk management objective for the hedge relationship but the change is in response to changes in the economic relationship between the hedged item and the hedging instrument (see section 6.2 above and section 8.2 below).

Such a determination is not a choice but based on facts and circumstances; for example, treatment as rebalancing is only permitted where entities change the quantity of hedged item compared to the quantity of hedging instrument (or *vice versa*) in response to changes in the economic relationship between them (i.e., changes to the hedge ratio are made), but the risk management objective otherwise continues as originally designated (see section 8.2 below). In contrast, the introduction of new types of hedging instruments would most likely be treated as a discontinuation and redesignation, as the use of new hedging instruments indicates that the entity no longer considers the existing hedging instruments to be sufficient to meet the risk management strategy.

A further example of a dynamic hedging strategy is a bank's interest rate risk management of an open portfolio of debt instruments, i.e., to which new exposures are frequently added, existing exposures mature, where frequent changes also occur to the hedged item(s) (see Illustration 8-8 in section 8.3.3 below). In that case, as the hedged items frequently change, the bank often looks at new hedging instruments and creates new relationships instead of continuing the relationship between the hedging instrument and the hedged item as they were designated previously. The risk management strategy remains the same, but there is no risk management objective that continues for those previously designated hedging relationships, which as such no longer exist. [IFRS 9.B6.5.24(b)]. Accounting for dynamic risk management of the associated risk in an open portfolio is the subject of a live project for the IASB (see section 10.1 below).

For any designated dynamic hedging strategies that do meet the IFRS 9 hedge accounting requirements, additional disclosures are required (see Chapter 50). [IFRS 7.23C].

6.3.3 Forecast transactions

In the case of a hedge of a forecast transaction, the documentation must identify the date on, or time period in which, the forecast transaction is expected to occur. This is because, in order to qualify for hedge accounting:

- The hedge must relate to a specific identified and designated risk [IFRS 9.6.3.7]
 - It must be possible to measure its effectiveness reliably [IFRS 9.6.3.2]
- And
- The hedged forecast transaction must be highly probable (see section 2.6.1 above) [IFRS 9.6.3.3]

To meet these criteria, entities are not required to predict and document the exact date a forecast transaction is expected to occur. However, the time period in which the forecast transaction is expected to occur is required to be identified and documented within a reasonably specific and generally narrow range of time from a most probable date, as a basis for measuring hedge ineffectiveness. Consideration of the effectiveness criteria would need to reflect differences in timing of the hedged and hedging cash flows in a manner consistent with the designated hedged risk (see sections 6.4.1 and 7.4.2 below).

If a forecast transaction such as a commodity sale is properly designated in a cash flow hedge relationship, and subsequently its expected timing changes to an earlier (or later) period, this does not necessarily affect the validity of the original designation. If the entity can conclude that this transaction is the same as the one designated as being hedged, then hedge accounting might be able to continue (see section 8.3.4 below). However, ineffectiveness could arise due to the change in timing, as the calculation of the change in fair value of the hedged item would be based on the up-to-date expectation of the timing of the hedged forecast transaction. For example, if a forecast transaction was originally thought to occur in five months but is now expected one month earlier, the hedging instrument (still with five months remaining) will be designated for the remaining period of its existence, which will exceed the period to the forecast sale. Ineffectiveness will arise from the comparison of the change in value of the hedged item (with four months remaining) to the hedging instrument with a residual maturity of five months (see section 7.4.4 below).

Further, hedged forecast transactions must be identified and documented with sufficient specificity so that when the transaction occurs, it is clear whether the transaction is, or is not, the hedged transaction. Therefore, a forecast transaction may be identified as the sale of the first 15,000 units of a specific product during a specified three-month period (see section 2.3.1 above), but it could not be identified as the last 15,000 units of that product sold because they cannot be identified when they occur. For the same reason, a forecast transaction cannot be specified solely as a percentage of sales or purchases during a period, without also specifying the forecast value of forecast sales or purchases. The need for documented specificity of the hedged item was reiterated by the IFRS IC in March 2019 in a discussion within the context of the Application of the Highly Probable Requirement when a Specific Derivative is Designated as a Hedging Instrument (IFRS 9 and IAS 39)²⁰ (see section 2.6.1 above). However, specific questions relating to power purchase agreements (PPA's) for renewable energy were submitted to the IFRS IC and escalated to the IASB in 2023. This included the difficulties resulting from the prohibition on designating a percentage of sales or purchases as the hedged item.

Subsequently, on 18 December 2024, the IASB published Amendments to IFRS 9 and IFRS 7 - Contracts Referencing Nature-dependent Electricity.²¹ The narrow scope amendments relate solely to contracts referencing nature-dependent electricity, which may not include all PPA contracts. The amendments address how the 'own-use' requirements apply to in-scope contracts, amend the designation requirements for a hedged item in a cash flow hedging relationship for in-scope contracts, and add new disclosure requirements. It is a narrow scope amendment that relates only to in-scope contracts that meet specified scope criteria and it should not be applied by analogy to other contracts, items or transactions (see section 3.2.6.A below).

It might also be possible for a forecast transaction of an aggregated exposure to be an eligible hedged item (i.e., combination of a forecast derivative and non-derivative transaction) (see Illustration 2-26 in section 2.7.3.D above). [IFRS 9.6.3.4].

²⁰ [IFRIC Update](#), March 2019, available on the IFRS Foundation's website.

²¹ [IFRS - IASB updates IFRS Accounting Standards for nature-dependent electricity contracts](#)

6.4 Assessing if the hedge effectiveness requirements are met

A hedging relationship can only qualify for hedge accounting if all the hedge effectiveness requirements are met, assuming the other qualifying criteria are also met (see section 6.1 above).

The hedge effectiveness requirements are as follows:

- There is an economic relationship between the hedged item and the hedging instrument (see section 6.4.1 below).
- The effect of credit risk does not dominate the value changes that result from that economic relationship (see section 6.4.2 below).

And

- The hedge ratio of the hedging relationship is the same as that resulting from the quantity of the hedged item that the entity actually hedges and the quantity of the hedging instrument that the entity actually uses to hedge that quantity of the hedged item. However, that designation shall not reflect an imbalance between the weightings of the hedged item and the hedging instrument that would create hedge ineffectiveness (irrespective of whether recognised or not) that could result in an accounting outcome that would be inconsistent with the purpose of hedge accounting. The second part of this requirement is an anti-abuse clause that is explained in more detail in section 6.4.3 below. [IFRS 9.6.4.1(c)].

An entity shall assess at the inception of the hedging relationship, and on an ongoing basis whether the hedge effectiveness requirements are met (see section 8.1 below). The assessment relates to expectations about hedge effectiveness and is therefore only forward looking. The standard does not specify a particular method for assessing whether the effectiveness requirements are met, however the methods selected must be documented within the hedge documentation. Further, if there are changes in circumstances that affect the hedge effectiveness, an entity might have to change the method for assessing whether a hedge relationship meets the hedge effectiveness requirements, without interrupting the hedge relationship (see section 6.3 above). [IFRS 9.B6.4.12, IFRS 9.B6.4.13, IFRS 9.B6.4.19].

How we see it

At a minimum, an entity must perform the ongoing assessment of hedge effectiveness at each reporting date or upon a significant change in circumstances affecting the hedge effectiveness requirements, whichever comes first.

'Reporting period' in this context refers to a period for which financial statements are produced in accordance with IFRS accounting standards. This includes both annual (full IFRS accounting standards) and interim (IAS 34 *Interim Financial Reporting*) financial reporting periods, if any. Other reporting periods such as internal reporting periods for which financial statements produced are not compliant with IFRS accounting standards are not 'reporting periods'. However, if an entity voluntarily performs this testing more frequently than their reporting periods, e.g., at the end of the period normally used by the entity for internal reporting purposes, this is not contrary to the objective of this requirement, provided this approach is consistently applied.

6.4.1 Economic relationship

The first effectiveness requirement means that the hedging instrument and the hedged item must generally be expected to move in opposite directions as a result of a change in the hedged risk. This is within the context of how the hedged item and hedging instrument have been designated as described in sections 2 and 3 above. [IFRS 9.B6.4.1]. The guidance does not require a belief that the value changes of the hedging instrument and the hedged item move in the opposite direction for the hedged risk in all circumstances, but that generally there is an expectation that they will systematically move in opposite directions. It is clear therefore, that there can be instances where the value changes in the hedged item and hedging instrument move in the same direction, although they will typically be expected to move in opposite directions.

IFRS 9 does not specify a method for assessing whether there is an economic relationship but provides the following guidance: [IFRS 9.B6.4.13]

Extract from IFRS 9

B6.4.13 This Standard does not specify a method for assessing whether a hedging relationship meets the hedge effectiveness requirements. However, an entity shall use a method that captures the relevant characteristics of the hedging relationship including the sources of hedge ineffectiveness. Depending on those factors, the method can be a qualitative or a quantitative assessment.

[IFRS 9.B6.4.13].

Determining which methods to use to assess whether there is an economic relationship, including statistical methods such as regression or sensitivity analysis, as well as the thresholds attached to them, will require judgement. No 'bright lines' are mandated by the guidance, nor is there a requirement for an entity to determine their own bright lines. [IFRS 9.BC6.238]. Instead, judgement is required in determining whether an economic relationship exists or not. However, it follows from the objective of the hedge accounting requirements, to represent the effect of an entity's risk management activities, that the main source of information to perform the assessment would be that an entity uses to perform its risk management activities. [IFRS 9.6.1.1, IFRS 9.B6.4.18].

In practice, an entity will normally have assessed the economic relationship for risk management purposes and, in most cases, assuming sound risk management, we would expect that this assessment to be appropriate for accounting purposes as well. However, in some cases, existing risk management techniques might not adequately consider all sources of ineffectiveness, such that additional analysis could be required, although this is likely to be rare. The chosen technique will depend on the complexity of the relationship, availability of data, the time value of money and the level of uncertainty of offset in the hedge relationship. If there are changes in circumstances that affect hedge effectiveness, an entity may have to change the method for assessing whether an economic relationship exists. [IFRS 9.B6.4.17]. However, if the economic relationship has in fact broken down, a change in assessment methodology would be insufficient to fix it, and the hedge relationship must be discontinued (see section 8.3 below).

The requirement that there is an economic relationship may be fulfilled qualitatively for many hedging relationships, as the nominal amount, maturity and underlying of the hedging instrument often matches, or is closely aligned with, the hedged risk. [IFRS 9.B6.4.14]. Even though it is not sufficient to focus solely on changes in value due to the hedged risk (in particular for the hedging instrument (see section 3.1 above)), the economic relationship will often still be capable of being demonstrated using a qualitative assessment. Drivers of fair value movements that are excluded from the hedge relationship (e.g., a change in credit risk on a hedged bond, if the designated risk is the benchmark rate), can be ignored for the purposes of the assessment of whether there is an economic relationship. However, a change in credit risk in the hedged item will still be relevant in consideration of the requirement that the impact of credit risk must not be of a magnitude such that it dominates the value changes (see section 6.4.2 below).

A qualitative assessment could also be used to determine that an economic relationship does not exist. For example, a hedge of one-sided risk in forecast purchases could be designated as being hedged by an out-of-the-money call option. If the main driver of value change in the option is expected to be the time value of the option, (perhaps because the option is expected to remain out of the money) then it can easily be seen the hedged item and hedging instrument are generally not expected to move in opposite directions with respect to the hedged risk. Of course, in this example, if the time value of the option were to be excluded from the hedge relationship (see section 3.6.4 above), then it would be easier to demonstrate that there is an economic relationship.

When the critical terms of the hedging instrument and hedged item are not closely aligned, and there is increased uncertainty about the extent of offset, such that hedge effectiveness is more difficult to predict, as noted above, IFRS 9 suggests that "it might only be possible for an entity to conclude [that there is an economic relationship] on the basis of a quantitative assessment." [IFRS 9.B6.4.16, IFRS 9.BC6.269]. The standard does not provide any further guidance on when a quantitative assessment might be required or how it would be made. However, it would seem to be most relevant when the hedged item and the hedging instrument are each based on prices derived from different markets, as in the example of WTI and Brent crude oil, discussed below, where there is a reasonable chance that the value changes of the hedging instrument and the hedged item will frequently move in the same direction. Although judgement will be required, we expect the need for a quantitative assessment over and above what is already undertaken for risk management purposes, to be relatively infrequent. [IFRS 9.B6.4.18].

The standard also mentions hedging relationships where a derivative with a non-zero fair value is designated as the hedging instrument, as an example of a situation where a quantitative assessment might be required to establish an economic relationship. It depends on the particular circumstances as to whether hedge effectiveness arising from the non-zero fair value could potentially have a magnitude that a qualitative assessment would not adequately capture. [IFRS 9.B6.4.15]. However, as noted above, the standard does not provide guidance on how large the non-zero fair value would have to be for a quantitative assessment to be required, or for an economic relationship to be considered not to exist.

The standard also mentions that a quantitative method, (e.g., regression analysis), might help demonstrate a suitable hedge ratio (see section 6.4.3 below). [IFRS 9.B6.4.16].

The following Illustration shows an approach that uses a qualitative assessment.

Illustration 6-4: Economic relationship between HKD and USD

An entity has foreign currency exposures in both Hong Kong dollars (HKD) and US dollars (USD). The entity aggregates its exposures in the two currencies and only uses USD linked hedges to hedge those currency exposures.

Because the HKD is pegged to the USD in a way that allows fluctuations only within a very narrow band (between HKD 7.75 - HKD 7.85 per USD) the entity concludes that an economic relationship exists between its USD linked hedges (with the USD as the underlying) and its HKD denominated foreign currency exposures.

The entity monitors the currency peg for changes and treats the movements of the HKD within the narrow band as a source of some ineffectiveness for all hedges in which the hedged item relates to amounts denominated in HKD.

The standard cites an example where the price of the hedging instrument is based on the West Texas Intermediate (WTI) price of oil whereas the price of the hedged item is based on the Brent crude oil price. The values of the hedging instrument and the hedged item can both move in the same direction if, for example, there is only a minor change in the relative underlyings of each of the hedging instrument and hedged item (i.e., the WTI and Brent oil prices) but there is a change in the price differential between the two. However, no guidance is provided as to how frequently this would have to happen so as to lead us to reject the expectation that they would 'generally' move in opposite directions. One possibility might be to use correlation analysis to demonstrate that there is, over time, a reliable and systematic price relationship. [IFRS 9.B6.4.4, IFRS 9.B6.4.5].

The assessment of whether there is an economic relationship must be based on an economic rationale rather than it just arising by chance, as could be the case if the relationship is based only on a statistical correlation. That is, causality cannot be assumed purely from correlation or, to quote the IASB, "the mere existence of a statistical correlation between two variables does not, by itself, support a valid conclusion that an economic relationship exists". [IFRS 9.B6.4.6].

Conversely, a statistical correlation could provide corroboration of an economic rationale. For example, if it can be seen that value drivers exist such that there is an expectation that the value of the hedged item and hedging instrument would generally move in opposite directions, but that significant sources of ineffectiveness exist within a relationship that might counteract the offset, then quantitative analysis could assist in determining whether an economic relationship exists or not. For example, in the case of a fair value hedge of an inflation risk component in a fixed rate bond (assuming it is determined that there is an eligible risk component (see section 2.2.6 above)), quantitative analysis could provide additional evidence as to whether an economic relationship exists or not. In summary, a quantitative assessment alone is not enough to establish an economic relationship, but it could be useful in a small number of cases to support a qualitative analysis that an economic relationship exists.

The assessment of the economic relationship, whether qualitative or quantitative, would need to consider, amongst other possible sources of mismatch between the designated hedged item and the hedging instrument, the following:

- Maturity
 - Volume or nominal amount
 - Cash flow dates
 - Interest rate basis, or quality and location basis differences
 - Day count methods
 - Features that arise only in either the designated hedged item or hedging instrument
 - Differences in valuation methods and inputs such as discount rates or credit risk
- And
- The extent that the hedging instrument is already 'in the money', or 'out of the money' when designated

The assessment must be forward looking at all times. This does not mean that retrospective offset is never relevant, but it can only be relied upon if there is a reasonable expectation that it is representative of the future. [IFRS 9.B6.4.12].

The assessment must include an analysis of the possible behaviour of the hedging relationship during its term to ascertain whether it can be expected to meet the risk management objective. [IFRS 9.B6.4.6]. The assessment must include consideration of all features of the hedging instrument and hedged item, and how they are expected to behave during the hedging relationship term. In the case of a deeply out of the money knock-out option which is not replicated in the hedged item, if there was no expectation that the knock-out feature will be exercised then it could be possible to determine that there is an economic relationship, despite the fact that offset would not arise if the knock-out feature occurred (see Illustration 3-3 in section 3.2.2 above). This assessment would necessarily be repeated as part of the subsequent assessment of effectiveness, if the result of the assessment was that an economic relationship did not exist, the hedge would be discontinued prospectively (see section 8.1 below).

In some cases, it could be difficult to demonstrate that an economic relationship exists for the entire life of the hedged item and hedging instrument, for example in the case of a hedging instrument with a longer life than the hedged item (see section 3.6.6 above), where there is a prepayment option within the hedged item, which is not matched by the hedging instrument (see section 2.3.2 above), in a documented rollover strategy (see section 7.7 below) or in a documented dynamic hedging strategy (see section 6.3.2 above).

The assessment as to whether an economic relationship exists must consider possible behaviours over the 'term' of the hedging relationship. [IFRS 9.B6.4.6]. The meaning of the 'term' of the hedging relationship is not explicitly defined. In some cases, it would be appropriate to assume that it refers to the remaining life of the hedging instrument or hedged item, however, an entity's risk management must not be ignored in the assessment. [IFRS 9.B6.4.18].

For example, in the case of a documented dynamic hedging strategy, using a process in which the hedged item(s) and/or the hedging instrument(s) do not remain the same for long (see section 6.3.2 above), there is an expectation that changes will be required in future to the hedge designation in order to continue to meet the risk management strategy. IAS 39 contained some explicit guidance on effectiveness testing for dynamic hedging strategies, that an entity "must be able to demonstrate an expectation that the hedge will be highly effective for a specified short period of time during which the hedge is not expected to be adjusted". [IAS 39.AG107, IAS 39.F.1.9].

How we see it

While the above guidance has not explicitly been carried forward into IFRS 9, it appears consistent with the requirement to consider the entity's risk management when assessing whether an economic relationship exists.

An entity's risk management is the main source of information to perform an assessment of whether a hedging relationship meets the effectiveness requirements, for example whether an economic relationship exists between the hedged item and the hedging instrument.

Accordingly, we believe that the term of the hedging relationship and the assessment of whether there is an economic relationship must be consistent with the risk management objective.

Hence if it is the case, and is documented as such, that sources of ineffectiveness, for example, prepayment risk or duration mismatches, are expected to result in changes to the risk management objective for that hedge relationship (typically in a dynamic hedging strategy), then the relevant term of the hedging relationship for assessment purposes is until the hedge is expected to be reset or reassessed, rather than the life of the hedging instrument or hedged item. However, all ineffectiveness must be measured and recorded in the usual way, irrespective of whether the hedge term for assessment purposes is considered to be shorter than the life of either the hedged item or instrument (see section 7.4 below).

Similarly, in the case of a documented roll over strategy (see section 7.7 below), as part of the entity's risk management there is an expectation that rollover hedging instruments will be transacted in order to maintain the documented risk management objective. Therefore, when making an assessment of the hedge term of a rollover hedging strategy for the purposes of assessing the existence of an economic relationship, we believe the relevant hedge term will reflect the timing of the expected rollover, despite the fact that the risk management objective will not change at that time (see section 7.7 below).

When using a statistical method such as regression analysis, either to corroborate an economic relationship or to determine a suitable hedging ratio, an entity is required to consider its expectations of future developments. A prominent historic example is negative interest rates in some European countries (see section 2.4.2 above). Many variable debt instruments such as mortgages include an explicit or implicit floor while the interest rates swaps used to hedge the variability of cash flows of those exposures usually do not. Although the interest cash flows of the hedged item and the variable leg of the hedging instrument might well have been highly correlated in the past, in an environment where interest rates are expected to be negative in the foreseeable future, this might no longer be expected because of the floor in the hedged item. This means that an entity needs to incorporate changes in expectations and re-calibrate its regression analysis accordingly.

It might also be necessary to ensure any expectations or rationale applied when undertaking a qualitative assessment to determine whether an economic relationship exists, continue to be relevant for the current economic environment.

6.4.2 Credit risk and the effectiveness assessment

IFRS 9 requires that, to achieve hedge accounting, the impact of credit risk must not be of a magnitude such that it dominates the value changes, even if there is an economic relationship between the hedged item and hedging instrument. Credit risk can arise on both the hedging instrument and the hedged item in the form of counterparty credit risk or the entity's own credit risk.

Judgement must be used in determining when the impact of credit risk is 'dominating' the value changes. But clearly, to 'dominate' would mean that there would have to be a very significant effect on the fair value of the hedged item or the hedging instrument (i.e., 'the loss (or gain) from credit risk frustrating the effect of changes in the underlyings on the value of the hedging instrument or hedged item, even if those changes were significant'). However, the standard provides guidance that in the case where there is little change in the underlyings in a particular period, the fact that even small credit risk related changes in the value of the hedging instrument or the hedged item might affect the value more than the underlying does not create dominance. [IFRS 9.B6.4.7].

Extract from IFRS 9

B6.4.8 An example of credit risk dominating a hedging relationship is when an entity hedges an exposure to commodity price risk using an uncollateralised derivative. If the counterparty to that derivative experiences a severe deterioration in its credit standing, the effect of the changes in the counterparty's credit standing might outweigh the effect of changes in the commodity price on the fair value of the hedging instrument, whereas changes in the value of the hedged item depend largely on the commodity price changes.

[IFRS 9.B6.4.8].

The assessment of the effect of credit risk on value changes for hedge effectiveness purposes, which often could be made on a qualitative basis, must not be confused with the requirement to measure and recognise the impact of credit risk on the hedging instrument and, where appropriate, the designated hedged item, which will normally give rise to hedge ineffectiveness recognised in profit or loss (see section 7.4.9 below).

The sections below provide more discussion on the assessment of whether credit risk arising in either the hedging instrument or hedged item dominates the value changes in the hedge relationship.

6.4.2.A Credit risk on the hedging instrument

IFRS 13 is clear that the effect of credit risk, both the counterparty's credit risk and the entity's own credit risk, must be reflected in the measurement of fair value (see Chapter 15). The effect of counterparty and own credit risk on the measurement of the hedging instrument will obviously result in some hedge ineffectiveness, as the same credit risk does not usually arise in the hedged item. However, the expected effect of that ineffectiveness must not be of a magnitude that it frustrates the offsetting impact of a change in the values of the hedging instrument and the hedged item that results from the economic relationship (as explained in section 6.4.2 above).

We expect the assessment of the effect of credit risk to be a qualitative assessment in most cases. For example, entities typically have counterparty risk limits defined as part of their risk management policy. The credit standing of the counterparties is monitored on a regular basis. However, a quantitative assessment of the impact of credit risk on the value changes of the hedging relationship might be required in some instances, if the counterparty's credit standing deteriorates.

Nowadays, most over-the-counter derivative contracts between financial institutions are collateralised by cash margins. Furthermore, initiatives in several jurisdictions, such as, the European Market Infrastructure Regulation (EMIR) in the European Union or the Dodd-Frank Act in the United States, have resulted in more derivative contracts being collateralised by cash (see section 8.3.5 below).

Cash collateralisation significantly reduces the credit risk for both parties involved, meaning that credit risk is unlikely to dominate the change in fair value of such hedging instruments. This is also true for any derivatives that are a settled-to-market (STM) interest rate swap, in which the daily variation margin is used to settle the interest rate swap's outstanding fair value (see section 8.3.6 below).

6.4.2.B Credit risk on the hedged item

The analysis of the hedged item is somewhat different, as credit risk does not apply to all types of hedged items. For example, while loan assets typically have counterparty credit risk and financial liabilities bear the issuing entity's own credit risk, inventory and forecast transactions do not pose credit risk.

Credit risk is defined as: *[IFRS 7 Appendix A]*

Extract from IFRS 7

Appendix A Defined terms

credit risk

The risk that one party to a financial instrument will cause a financial loss for the other party by failing to discharge an obligation.

Credit risk cannot dominate the value change in a hedge of a forecast transaction as the transaction is, by definition, only anticipated but not committed. *[IFRS 9 Appendix A]*. Similarly, inventory does not involve credit risk.

This should be contrasted with the assessment of whether a forecast transaction is highly probable (see section 2.6.1 above). Even though such a transaction does not involve credit risk, depending on the possible counterparties for the anticipated transaction, the credit risk that affects them can indirectly affect the assessment of whether the forecast transaction is highly probable. For example, assume an entity sells a product to only one particular customer abroad for which the sales are denominated in a foreign currency and the entity does not have alternative customers to sell the product to in that currency (or other sales in that currency). In that case, the credit risk of that particular customer would indirectly affect the likelihood of the entity's forecast sales in that currency occurring. Conversely, if the entity has a wider customer base for sales of its product that are denominated in the foreign currency then the potential loss of a particular customer would not significantly (or even not at all) affect the likelihood of the entity's forecast sales in that currency.

It is noted in IFRS 9 that a magnitude that gives rise to dominance is one that would result in the loss (or gain) from credit risk frustrating the effect of changes in the underlying on the value of the hedging instrument or the hedged item, even if those changes were significant. *[IFRS 9.B6.4.7]*. The guidance refers to both a loss and a gain due to changes in credit risk for the hedged item and the hedging instrument. However, it will only be relevant to consider a decrease in credit risk for the hedged item, if such a change in credit risk would frustrate the hedge relationship. For example, a decrease in credit risk in a hedged financial asset is unlikely to cause the level of offset within the hedge relationship to become erratic, if credit risk is excluded from the hedge relationship. In contrast, this would not be the case for an increase in the credit risk of hedged financial assets, as higher levels of credit risk could affect the hedged cash flows themselves.

For regulatory and accounting purposes, banks usually have systems in place to determine the credit risk on their loan portfolios. Therefore, banks are likely to be able to identify loans for which credit risk is so high that it would require an assessment of whether credit risk is dominating the value changes in the hedging relationship.

The introduction of the impairment model of IFRS 9 (see Chapter 47) raised the question of whether there is a linkage between:

- The impairment model concept of a significant increase in credit risk (i.e., the move from 'stage one' to 'stage two') and the subsequent transfer of a credit-impaired financial assets to 'stage three'
- And
- The concept of when the effect of credit risk dominates the value changes of the hedged item that represent the hedged risk

There is no direct link between the stages of the impairment model and credit risk eligibility criterion of the hedge accounting model. However, in practice, an entity might consider the indicators cited in the definition of a credit-impaired financial asset (see Chapter 47). This is because those indicators characterise situations with a magnitude of credit risk that normally suggests that its effect would dominate the value changes of the hedged item that represent the hedged risk. This implies that the hedge effectiveness criteria would cease to be met no later than when a financial asset is classified as credit-impaired (i.e., in stage three). How much earlier the hedge effectiveness criteria might be failed is a matter of judgement, which might need to be supported by quantitative assessment in some situations. But also, in the context of stage three of the impairment model, it should be remembered that the effect of credit risk on the fair value of an item involves not only the probability of default but also the loss given default, whereas the indicators cited in the definition of a credit-impaired financial asset relate only to the probability of default. That difference is relevant when assessing whether credit risk is dominant in the case of items that are highly collateralised.

In practice, we expect that entities with a sound risk management would be unlikely to struggle with the assessment of when the effect of credit risk dominates the value changes of the hedged item that represent the hedged risk. This is because such entities would have developed suitable criteria for when risk exposures can no longer be economically hedged because credit risk creates too much uncertainty as to whether that exposure will eventually crystallise as per the terms in the contract from which it arises. Entities normally evaluate this for risk management purposes because they want to avoid being 'over-hedged' as a result of the offset from the hedged item for the gains or losses on the hedging instrument being eroded by credit risk. In other words, this is predominantly an economic question rather than an accounting consideration (similar to the discussion in section 6.4.2.A above regarding the credit risk of hedging instruments and entities' criteria for selecting counterparties for those instruments).

It has been suggested that there is also interaction between the hedge accounting model and the impairment model regarding the effect that a fair value hedge might have on the measurement of the expected credit loss (ECLs). Specifically, as IFRS 9 requires that expected cash flows are discounted at the effective interest rate (EIR) for the purposes of calculation of the ECL, the question is whether fair value hedge accounting changes the EIR of hedged financial assets for this purpose.

Where the hedged item in a fair value hedge is a financial instrument (or component thereof) for which the effective interest method of accounting is used, the adjustment must be amortised to profit or loss. Amortisation may begin as soon as the adjustment exists and shall begin no later than when the hedged item ceases to be adjusted for hedging gains and losses. The adjustment must be based on a recalculated effective interest rate at the date amortisation begins (see sections 7.1.2 and 8.3.1 below). [IFRS 9.6.5.10].

How we see it

As a fair value hedge adjustment is only required to be amortised when the hedged item ceases to be adjusted for changes in fair value attributable to the risk being hedged, arguably there is no need to adjust the EIR until then, and hence the rate used to discount ECLs. We believe the requirement is not clear and that there is an accounting policy choice on the matter (see Chapter 47).

If an accounting policy choice is made that fair value hedges do change the EIR, then the EIR used for discounting the ECLs must be adjusted for the effects of fair value hedging. Under IFRS 9, every debt instrument recorded at amortised cost or at fair value through other comprehensive income has an associated ECL. This would mean, for every fair value hedge in relation to such financial assets, the measurement of the ECLs would require taking into account the effect of the fair value hedge accounting.

The systems used to assess the credit risk of loans would also usually permit banks to determine the appropriate economic hedge when hedging the interest rate risk of such loans, as illustrated by Illustration 6-5 below:

Illustration 6-5: Designating interest rate hedges of loan assets when credit risk is expected

Assume a bank wishes to hedge the interest rate risk of a portfolio of non-pre-payable loans that have similar credit risk characteristics. Economically, the bank will hedge only the cash flows it expects to collect. When expecting to collect 95% of all cash flows in a loan portfolio, the bank is likely to designate a bottom layer nominal amount reflecting the first 95% of cash flows only. A designation of a nominal amount equal to more than 95% would result in an economic over-hedge and would also increase the risk of credit risk dominating the value changes of the hedging relationship.

The designation of such a nominal component (often referred to as a bottom layer) is possible under IFRS 9 (as discussed in section 2.3 above). This type of designation would require that all items included in the layer are exposed to the same hedged risk so that the measurement of the hedged layer is not significantly affected by items that make up the 95% layer from the overall 100% of the portfolio. [IFRS 9.6.6.3(c)]. Therefore, the entity has to designate the same kind of benchmark interest rate risk component of each loan to make up the bottom layer. If there is a deterioration in the credit risk of a particular loan that results in credit risk dominating the economic relationship with the benchmark interest rate, such that its benchmark interest rate risk component will no longer qualify to be designated as a hedged item, it would not be considered to be part of the bottom layer unless and until those loans for which credit risk dominates the economic relationship exceed 5% of the portfolio.

For pre-payable loans the designation is more complicated as there are additional criteria to be applied in order to designate a bottom layer in such a portfolio within a fair value hedge (see section 2.3.2 above).

The example should not be taken to imply that for an individual loan with an expected loss of, say, 5% an entity could not hedge the interest rate risk using an interest rate swap that has a notional amount equal to the loan's face value. However, if the loan deteriorated in its credit quality to an extent where the credit risk-related changes in fair value start to dominate the interest rate risk-related changes, the hedging relationship would have to be discontinued.

6.4.3 The hedge ratio

The hedge ratio is the ratio between the amount of hedged item and the amount of hedging instrument. For many hedging relationships, the hedge ratio would be 1:1 as the underlying of the hedging instrument perfectly matches the designated hedged risk.

Some hedging relationships could include basis risk such that the fair value changes of the hedged item and the hedging instrument do not have a simple 1:1 relationship. In such cases, risk managers will generally set the hedge ratio so as to be other than 1:1, in order to improve the effectiveness of the hedge. Consequently, the third IFRS 9 hedge effectiveness requirement is that the hedge ratio used for accounting will ordinarily be the same as that used for risk management purposes. [IFRS 9.6.4.1(c)(iii), IFRS 9.B6.4.9].

Illustration 6-6: Setting the hedge ratio

An entity purchases a raw material whose price is at a discount to the commodity benchmark price, reflecting that the raw material is not yet processed to the same extent as the benchmark commodity, as well as quality differences. The entity runs a rolling 12 month regression analysis at each month end to ascertain that the price of the commodity in the futures market and the price of the raw material remain highly correlated. The slopes of the regression analyses (commodity benchmark price to raw material price) over recent months varied between 1.237 and 1.276.

The entity considers that the pattern of its regression analyses is consistent with its longer term view that the raw material trades at an approximately 20% discount to the commodity benchmark price and does not indicate a change in trend but fluctuations around that discount. Therefore, the entity uses a notional amount of 1 tonne of a forward contract for the benchmark commodity to hedge highly probable forecast purchases of 1.25 tonnes of the raw material. Note that this is not exactly the same as the particular slope of the most recent monthly regression, which is not required because the standard requires only that the entity uses the hedge ratio that it actually uses for risk management purposes, and not that it is required to minimise ineffectiveness. The example also illustrates what the standard acknowledges: there is no 'right' answer, as different entities would run different regression analyses (e.g., in terms of frequency and data inputs used, which means there is no one hedge ratio that could be required). The fluctuation of the actual discount around the particular hedge ratio chosen for designating the hedging relationship will give rise to some ineffectiveness that will need to be recorded.

However, the standard requires the hedge ratio for accounting purposes to be different from the hedge ratio used for risk management if the latter hedge ratio reflects an imbalance that would create hedge ineffectiveness “that could result in an accounting outcome that would be inconsistent with the purpose of hedge accounting.” [IFRS 9.6.4.1(c)(iii), IFRS 9.B6.4.10]. This complex language was introduced because the Board is specifically concerned with deliberate ‘under-hedging’, either to minimise recognition of ineffectiveness in cash flow hedges or the creation of additional fair value adjustments to the hedged item in fair value hedges. [IFRS 9.B6.4.11(a)].

Illustration 6-7: Deliberate under-hedging in a cash flow hedge to avoid recognition of ineffectiveness

IFRS 9 requires the cash flow hedge reserve to be adjusted for the lower of (a) the cumulative gain or loss on the hedging instrument or (b) the cumulative change in fair value of the hedged item (see section 7.2 below). [IFRS 9.6.5.11(a)]. If (a) exceeds (b), the difference is recognised in profit or loss as ineffectiveness. On the other hand, no ineffectiveness is recognised if (b) exceeds (a).

An entity has highly probable forecast purchases of a raw material used in its manufacturing process. The average volume of raw material purchases is expected to be CU200 million per month. The entity wishes to hedge the commodity price risk on those forecast purchases. The only derivative available does not have an underlying risk exactly matching the one from the actual raw material hedged. The slope of a linear regression analysis is 0.93, indicating the ideal hedge ratio.

To seek to avoid recognition of accounting ineffectiveness, the entity ensures (b) will exceed (a), applying the accounting requirement discussed above. It enters into derivatives with a notional amount of only CU150m per month and designates the CU150 million of derivatives as hedging instruments in cash flow hedges of highly probable forecast purchases of CU200 million (thereby setting the hedge ratio at 0.75:1).

In this scenario, the hedge ratio would be considered unbalanced and only entered into to avoid recognition of accounting ineffectiveness. For hedge accounting purposes, the hedge ratio would have to be based on the expected sensitivity between the hedged item and the hedging instrument (in this example possibly around the 0.93:1 based on the linear regression analysis, which would give a hedged volume of CU161m). As a result, if the actual relative change in the fair value of the hedging instrument is greater than that on the hedged item because the relationship between the underlyings changes, some ineffectiveness will have to be recognised.

Illustration 6-8: Deliberate under-hedging in a fair value hedge to create fair value accounting

An entity acquires a CU50 million portfolio of debt instruments. The debt instruments fail the ‘cash flow characteristics test’ of IFRS 9 (i.e., the contractual cash flows do not solely represent payments of principal and interest on the principal amount outstanding) and are therefore accounted for at fair value through profit or loss (see Chapter 44). [IFRS 9.4.1.2(b), IFRS 9.4.1.2A(b), IFRS 9.4.1.4].

The treasurer dislikes the profit or loss volatility resulting from the fair value accounting. He realises that one of the entity’s fixed rate bank borrowings has a similar term structure and that fair value changes on the liability due to interest rate risk would more or less offset the fair value changes on the asset portfolio. However, at the time of entering into the bank borrowing, the entity did not apply the fair value option to this liability (see Chapter 44).

The treasurer enters into a CU1 million receive fixed/pay variable interest rate swap (IRS) and designates the IRS in a fair value hedge of CU50 million of fixed rate liability (thereby setting the hedge ratio at 0.02:1). As a result, the entire CU50 million of liability would be adjusted for changes in the hedged interest rate risk. There would still be a measurement mismatch as only fair value changes due to the interest rate risk components would offset between the portfolio of debt instruments and the designated hedged liability and there would be no offset for fair value changes in the portfolio of debt instruments due to other drivers.

In this scenario, the hedge ratio is unbalanced as the real purpose of the hedging relationship is to achieve fair value accounting (related to changes in interest rate risk) for CU49 million of the liability. The hedge ratio used for hedge accounting purposes would have to be different (likely close to 1:1). Such a designation is also unlikely to be directionally consistent with the entity’s risk management objective and strategy and so would be precluded for that reason also (see section 6.2.1 above).

Alternatively, the entity could consider designating the CU50 million portfolio of debt instruments as the hedging instrument in a fair value hedge of the fixed rate bank borrowings for interest rate risk (see section 3.3 above), in that case a 1:1 hedge ratio might also be required.

However, the same mismatch as mentioned previously would still arise, as all changes in fair value of non-derivative hedging instruments must be considered to be part of the hedge relationship. For a hedging instrument it is not possible to restrict the fair value changes to interest rate risk only.

The above examples are of course extreme scenarios and instances of unbalanced hedge designations are likely to be rare; IFRS 9 does not however require an entity to designate a 'perfect hedge'. For instance, if the hedging instrument is only available in multiples of 25 metric tonnes as the standard contract size, an imbalance due to using, say, 400 metric tonnes nominal value of hedging instrument to hedge 409 metric tonnes of forecast purchases, would not be regarded as resulting in an outcome 'that would be inconsistent with the purpose of hedge accounting' and so would meet the qualifying criteria. [IFRS 9.B6.4.11(b)].

The subsequent prospective effectiveness assessment requires consideration as to whether the accounting hedge ratio is still appropriate, or indeed whether a change is required. This 'rebalancing' of a live hedge relationship is further discussed in section 8.2 below.

7 Accounting for effective hedges

If any entity chooses to designate a hedging relationship of a type described in section 5 above, between a hedged item and a hedging instrument as described in sections 2 and 3 above and it meets the qualifying criteria set out in section 6 above, the accounting for the gain or loss on the hedging instrument and the hedged item will be as set out in this section. *[IFRS 9.6.1.2, IFRS 9.6.5.1].*

7.1 Fair value hedges

7.1.1 Ongoing fair value hedge accounting

If a fair value hedge (see section 5.1 above) meets the qualifying conditions set out in section 6 above during the period, it must be accounted for as follows:

- The gain or loss on the hedging instrument shall be recognised in profit or loss (or OCI if the hedging instrument hedges an equity instrument for which an entity has elected to present changes in fair value in OCI in accordance with IFRS 9.5.7.5 (see section 2.6.3 above and Chapter 44)).

And

- The hedging gain or loss on the hedged item shall adjust the carrying amount of the hedged item (if applicable) and be recognised in profit or loss.

If the hedged item is a debt instrument (or a component thereof) that is measured at fair value through OCI in accordance with IFRS 9.4.1.2.A (see Chapter 44) the hedging gain or loss on the hedged item shall be recognised in profit or loss.

If the hedged item is an equity instrument for which an entity has elected to present changes in fair value in OCI, those amounts shall remain in OCI.

Where a hedged item is an unrecognised firm commitment (or a component thereof), the cumulative change in the fair value of the hedged item subsequent to its designation is recognised as an asset or liability with a corresponding gain or loss recognised in profit or loss. *[IFRS 9.6.5.8].*

The hedging gain or loss on the hedged item is not necessarily the full fair value change in the hedged item, but reflects the change in value since designation of the designated portion or component of the hedged item (see sections 2.2 and 2.3 above) attributable to the hedged risk. Any changes in the fair value of the hedged item that are unrelated to the hedged risk (or occurred prior to the hedge designation) must only be recognised in compliance with the normal requirements of IFRS accounting standards. *[IFRS 9.B6.3.11].*

The gain or loss on the hedging instrument for the purposes of accounting for a fair value hedge, refers to all changes in fair value of the hedging instrument since designation in the hedge relationship. Only fair value changes with respect to the time value of an option, forward element of a forward contract or foreign currency basis spreads if excluded from the hedge designation (see sections 3.6.4 and 3.6.5 above), or a documented excluded proportion of the instrument (see section 3.6.1 above) are not included within the gain or loss on the hedging instrument.

Hedge ineffectiveness is the extent to which the changes in the fair value or the cash flows of the hedging instrument are greater or less than those on the hedged item. *[IFRS 9.B6.3.11, IFRS 9.B6.4.1].* Where hedge ineffectiveness arises in a fair value hedge, a net amount will be recognised in profit or loss, (unless the hedged item is an equity instrument for which an entity has elected to present changes in fair value in OCI in accordance with IFRS 9.5.7.5, in which case it will be recognised in OCI). Hedge ineffectiveness is an important concept with IFRS 9, and measurement of it is considered more fully in section 7.4 below.

Although not clearly stated in IFRS 9, it is implied that the gain or loss on the hedging instrument (at least to the extent it is effective) and the hedging gain or loss on the hedged item is likely to be recognised in the same line item in profit or loss, to reflect the offsetting effect of hedge accounting (see Chapter 50).

[IFRS 9.6.5.8].

The following simple examples illustrate how fair value hedge treatment would apply to a hedge of fair value interest rate risk on an investment in fixed rate debt. Illustration 7-1 below demonstrates the accounting for a fixed rate debt held at amortised cost as well as one measured at fair value through OCI.

Illustration 7-1: Fair value hedge

At the beginning of Year 1 an investor purchases a fixed rate debt security for £100. At the end of Year 1, the fair value of the debt security is £110. In order to protect this value, at the end of Year 1 the investor enters into a hedge by acquiring an interest rate derivative with a nil fair value and designates it in a fair value hedge of interest rate risk. By the end of Year 2, the derivative has a fair value of £5 and the debt security has a corresponding decline in fair value. Fair value changes in both the fixed rate debt security and the derivative have only occurred due to interest rates.

Case 1: the investor has classified the fixed rate debt security at amortised cost (see Chapter 44).

Case 2: the investor classifies the fixed rate debt security as measured at fair value through OCI (see Chapter 44).

Case 1: debt held at amortised cost

The investor would record the following accounting entries:

Year 1

Beginning of year

	£	£
Dr Debt security	100	
Cr Cash		100

To reflect the acquisition of the debt security.

Although the fair value of the debt security has changed by the end of Year 1, no accounting entries are applied as it is held at amortised cost.

Year 2

Beginning of year

	£	£
Dr Derivative	-	
Cr Cash		-

To record the acquisition of the derivative at its fair value of nil.

End of year

	£	£
Dr Derivative	5	
Cr Profit or loss		5

To recognise the increase in the derivative's fair value in profit or loss.

	£	£
Dr Profit or loss	5	
Cr Debt security		5

Applying fair value hedge accounting, to recognise the decrease in the fair value of the debt security due to changes in interest rates since the hedge was designated at the beginning of Year 2.

Case 2: debt held at fair value through OCI

The investor would record the following accounting entries:

Year 1

Beginning of year

	£	£
Dr Debt security	100	
Cr Cash		100

To reflect the acquisition of the debt security.

End of year

	£	£
Dr Debt security	10	
Cr Other comprehensive income		10

To record the increase in the debt security's fair value in other comprehensive income.

Year 2

Beginning of year

	£	£
Dr Derivative	-	
Cr Cash		-

To record the acquisition of the derivative at its fair value of nil.

End of year

	£	£
Dr Other comprehensive income	5	
Cr Debt security		5

To record the decrease in the debt security's fair value in other comprehensive income.

	£	£
Dr Derivative	5	
Cr Profit or loss		5

To recognise the increase in the derivative's fair value in profit or loss.

	£	£
Dr Profit or loss	5	
Cr Other comprehensive income		5

Applying fair value hedge accounting, to recognise the decrease in the fair value of the debt security due to changes in interest rates since the hedge was designated at the beginning of Year 2.

For Case 1 in Illustration 7-1 above, the £5 credit to the carrying amount of the debt security reflects a change to the usual amortised cost accounting entries. However, for Case 2, the treatment is consistent with the usual accounting for instruments measured at fair value through OCI in accordance with IFRS 9.4.1.2A (see Chapter 46). In both Cases, the £5 debit to profit or loss is a change to the usual accounting; the entry would not occur at all in Case 1 under amortised cost accounting and would be recognised in OCI rather than profit or loss in Case 2.

It can be seen that the 'benefit' of fair value hedge accounting is that the change in fair value of the hedged item with respect to interest rate risk provides offset in profit or loss for the change in fair value of the hedging instrument. In this simple example the offset is 'complete' as the change in fair value of the hedged item with respect to interest rate risk and the change in fair value of the hedging instrument are equal and opposite, however this will not always be the case. Where offset is not complete, some ineffectiveness will remain in profit or loss (see section 7.4 below).

As illustrated above for Case 1, for hedged items not held at fair value, the adjustment to both the carrying amount of the hedged item and profit or loss would only occur as a result of the application of fair value hedge accounting. However, when hedging the foreign currency risk on a foreign currency monetary item, IAS 21 retranslation gains or losses would be recognised in profit or loss in any event. Accordingly, any incremental adjustment to the carrying amount as part of fair value hedge accounting must not include the retranslation effect again (see section 5.1.2 above).

Where an unrecognised firm commitment is designated as a hedged item in a fair value hedge, the application of fair value hedge accounting requires that the subsequent cumulative change in its fair value attributable to the hedged risk be recognised as an asset or liability with a corresponding gain or loss recognised in profit or loss. Thereafter, the firm commitment would be a recognised asset or liability (albeit that its carrying amount will not represent either its cost or, necessarily, its fair value). The changes in the fair value of the hedging instrument would also be recognised in profit or loss. [IFRS 9.6.5.8(b)].

It can be seen that applying fair value hedge accounting adjustments does not change the accounting for the hedging instrument (unless it hedges an equity instrument for which an entity has elected to present changes in fair value in OCI, or if the time value of an option, forward element of a forward contract or foreign currency basis spreads are excluded from the hedge and accounting for the costs of hedging is applied (see section 7.5 below)). This is true whether the hedging instrument is a derivative or non-derivative instrument. For example, if a foreign currency cash instrument was designated as the hedging instrument in a fair value hedge (see section 3.3.1 above), the foreign currency component of its carrying amount would continue to be measured in accordance with IAS 21.

7.1.2 Dealing with adjustments to the hedged item

In general, adjustments to the hedged asset or liability arising from the application of hedge accounting as described in section 7.1.1 above are dealt with in accordance with the normal accounting treatment for that item. For example, copper inventory might be the hedged item in a fair value hedge of the exposure to changes in the copper price. In this case, the adjusted carrying amount of the copper inventory becomes the cost basis for the purpose of applying the lower of cost and net realisable value test under IAS 2 (see Chapter 23). [IAS 39.F.3.6]. See also section 8.3.1 below for further discussion on the accounting for discontinuation of fair value hedges.

Where the hedged item is a financial instrument (or component thereof) for which the effective interest method of accounting is used, the adjustment must be amortised to profit or loss. Amortisation may begin as soon as the adjustment exists and must begin no later than when the hedged item ceases to be adjusted for hedging gains and losses. The adjustment must be based on a recalculated effective interest rate at the date amortisation begins. [IFRS 9.6.5.10]. The purpose of the amortisation is to reflect the effect of the fair value hedge in the profit and loss, but also to ensure the adjustment is fully amortised by maturity. If the fair value of the hedged component is zero when designated and the hedge relationship remains in place to its maturity, it is likely that no additional amortisation will be required as the cumulative fair value adjustment to the hedged item will naturally revert to zero through ongoing fair value hedge accounting adjustments.

However, in other circumstances, such as when the fair value of the hedged component is not zero on designation and/or if the hedge relationship does not remain in place throughout the life of the hedge relationship, the cumulative fair value adjustment to the hedged item will not naturally revert to zero. This has the effect that a residual amount will remain on maturity of the hedged item unless an adjustment to the effective interest rate amortisation is applied. The purpose of this adjustment to the effective interest rate is to ensure the carrying amount of the hedged item is equal to its redemption amount on maturity.

If the hedged item is measured at fair value through OCI in accordance with IFRS 9.4.1.2A, it is the cumulative gain or loss previously recognised in OCI that is adjusted, not the carrying amount. [IFRS 9.6.5.10].

See Chapter 47 for details on how the recalculated effective interest rate interacts with the IFRS 9 expected credit loss calculation.

When a hedged item in a fair value hedge is a firm commitment (or component thereof) to acquire an asset or assume a liability, the initial carrying amount of the asset or liability that results from the entity meeting the firm commitment is adjusted to include the cumulative change in the fair value of the hedged item that was recognised in the statement of financial position. [IFRS 9.6.5.9].

Illustration 7-2: Hedge of a firm commitment to acquire equipment

Company X has the euro as its functional currency. It has chosen to treat all hedges of foreign currency risk associated with firm commitments as fair value hedges. In January 20X2 it contracts with a US supplier (with the US dollar as its functional currency) to purchase an item of machinery it intends to use in its business. The machinery will be delivered at the start of July 20X2 and the contracted price, payable on delivery, is US\$1,000.

X has no appetite to take on foreign currency exchange risk in relation to euro/US dollar exchange rates and so contracts with a bank to purchase US\$1,000 at the start of July in exchange for €900 (the six-month forward exchange rate is US\$1:€0.90). In other words, X has effectively fixed the price it will pay for the machinery (in euro terms) at €900.

The fair value of the forward exchange contract at the end of March 20X2 (X's year end) is €30 positive to X, and on delivery is €50 positive to X (the spot exchange rate on delivery is US\$1:€0.95). Assuming the hedge is perfectly effective (this might be the case if the hedged risk is identified as the forward exchange rate - see section 7.4.7 below, and it is assumed that no sources of ineffectiveness such as foreign currency basis spreads exist - see section 7.4.8 below) and meets all the requirements for hedge accounting, the journal entries to record this hedging relationship would be as follows:

January 20X2

No entries are required as the firm commitment is unrecognised, the forward exchange contract is recognised but has a zero fair value and no cash is paid or received.

March 20X2		€	€
Dr	Forward exchange contract	30	
	Cr Profit or loss		30

To recognise the change in fair value of the forward exchange contract in profit or loss.

		€	€
Dr	Profit or loss	30	
	Cr Firm commitment		30

To recognise the change in fair value of the (previously) unrecognised firm commitment in respect of changes in forward exchange rates in profit or loss.

	July 20X2	€	€
Dr	Forward exchange contract	20	
	Cr Profit or loss		20

To recognise the change in fair value of the forward exchange contract in profit or loss.

		€	€
Dr	Profit or loss	20	
	Cr Firm commitment		20

To recognise the change in fair value of the (now recognised) firm commitment in respect of changes in forward exchange rates in profit or loss.

		€	€
Dr	Cash	50	
	Cr Forward exchange contract		50

To record the settlement of the forward exchange contract at its fair value. (Only the net cash movement is reflected here, although settlement is likely to be on a gross basis).

		€	€
Dr	Machinery	950	
	Cr Cash		950

To record the settlement of the firm commitment at the contracted price of US\$1,000 at the spot rate of US\$1:€0.95.

		€	€
Dr	Firm commitment	50	
	Cr Machinery		50

To remove the carrying amount of the firm commitment from the statement of financial position and adjust the initial carrying amount of the machinery that results from the firm commitment.

In summary, the result of these accounting entries is as follows:

		€	€
Dr	Machinery	900	
	Cr Cash		900

Which is somewhat reassuring given the starting presumption, i.e., that X had effectively fixed the purchase price of its machine at €900.

7.2 Cash flow hedges

7.2.1 Ongoing cash flow hedge accounting

If a cash flow hedge (see section 5.2 above) meets the qualifying conditions set out in section 6 above during the period, it must be accounted for as follows: [IFRS 9.6.5.11, IAS 1.92, IFRS 18.90]

Extract from IFRS 9

- 6.5.11** As long as a cash flow hedge meets the qualifying criteria in paragraph 6.4.1, the hedging relationship shall be accounted for as follows:
- (a) the separate component of equity associated with the hedged item (cash flow hedge reserve) is adjusted to the lower of the following (in absolute amounts):
 - (i) the cumulative gain or loss on the hedging instrument from inception of the hedge; and
 - (ii) the cumulative change in fair value (present value) of the hedged item (ie the present value of the cumulative change in the hedged expected future cash flows) from inception of the hedge.
 - (b) the portion of the gain or loss on the hedging instrument that is determined to be an effective hedge (ie the portion that is offset by the change in the cash flow hedge reserve calculated in accordance with (a)) shall be recognised in other comprehensive income.
 - (c) any remaining gain or loss on the hedging instrument (or any gain or loss required to balance the change in the cash flow hedge reserve calculated in accordance with (a)) is hedge ineffectiveness that shall be recognised in profit or loss.
 - (d) the amount that has been accumulated in the cash flow hedge reserve in accordance with (a) shall be accounted for as follows:
 - (i) if a hedged forecast transaction subsequently results in the recognition of a non-financial asset or non-financial liability, or a hedged forecast transaction for a non-financial asset or a non-financial liability becomes a firm commitment for which fair value hedge accounting is applied, the entity shall remove that amount from the cash flow hedge reserve and include it directly in the initial cost or other carrying amount of the asset or the liability. This is not a reclassification adjustment (see IAS 1) and hence it does not affect other comprehensive income.
 - (ii) for cash flow hedges other than those covered by (i), that amount shall be reclassified from the cash flow hedge reserve to profit or loss as a reclassification adjustment (see IAS 1) in the same period or periods during which the hedged expected future cash flows affect profit or loss (for example, in the periods that interest income or interest expense is recognised or when a forecast sale occurs).
 - (iii) however, if that amount is a loss and an entity expects that all or a portion of that loss will not be recovered in one or more future periods, it shall immediately reclassify the amount that is not expected to be recovered into profit or loss as a reclassification adjustment (see IAS 1).

[IFRS 9.6.5.11].

No specific guidance is provided on how to perform the recoverability test set out in IFRS 9.6.5.11(d)(iii) above, hence a hierarchy of guidance must be considered in the selection of an appropriate accounting policy, in line with IAS 8 *Accounting Policies, Changes in Accounting Estimates and Errors* (see Chapter 3). [IAS 8.10].

Accordingly, consideration is likely to be given to the guidance on the recoverability of assets which is contained in other IFRS accounting standards such as IAS 2 on determining net realisable value of inventory, IAS 36 *Impairment of Assets* on impairment testing of non-financial assets or IAS 37 *Provisions, Contingent Liabilities and Contingent Assets* on onerous contracts. The outcome of applying these different methodologies could differ. Therefore, judgement is required in determining the most appropriate methodology based on the specific facts and circumstances of the hedge relationship. Although the recoverability test is described with respect to amounts that have been accumulated in the cash flow hedge reserve it also appears to be relevant for amounts accumulated in other comprehensive income from transaction related hedges for which the cost of hedging guidance has been applied (see section 7.5.1 below). [IFRS 9.BC6.399].

Unlike fair value hedge accounting (see section 7.1.1 above), the application of cash flow hedge accounting does not amend the accounting for the hedged items, it is the accounting for the hedging instrument that is changed. However, cash flow hedge accounting only changes the accounting for the designated portion of the hedging instrument. For example, if the time value of an option, forward element of a forward contract or foreign currency basis spreads are excluded from the hedge (see section 7.5 below) or a proportion of the instrument is not designated (see section 3.6.1 above), the accounting for those excluded elements remains unchanged by cash flow hedge accounting. However, if the costs of hedging guidance is applied to the excluded time value of an option, forward element of a forward contract or foreign currency basis spreads, the accounting for those excluded portions will also change (see section 7.5 below).

The requirements set out in (a) above are often referred to as the 'lower of' requirements. This accounting treatment is shown in the following Illustrations.

Illustration 7-3: Cash flow hedge of anticipated commodity sale

On 30 September 20X2, Company A hedges the anticipated sale of 24 tonnes of pulp on 1 March 20X3 by entering into a short forward contract. The contract requires net settlement in cash, determined as the difference between the future spot price of 24 tonnes of pulp on a specified commodity exchange and £1m. A expects to sell the pulp in a different, local market.

A designates the forward contract as the hedging instrument in a cash flow hedge of changes in the pulp price on the cash flows from the anticipated sales. A determines that the hedge effectiveness requirements and the other hedge accounting criteria are met (see section 6 above).

On 31 December 20X2, the spot price of pulp has increased both in the local market and on the exchange, although the increase in the local market exceeds the increase on the exchange. As a result, the present value of the expected cash inflow from the sale on the local market is £1.1 million and the fair value of the forward is £85,000 negative. The hedge is still determined to meet the hedge effectiveness criteria. In particular Company A considers the difference in relative value changes in the local and exchange market price of pulp to be fluctuations around an appropriate hedge ratio, rather than an indication that the existing 1:1 hedge ratio is no longer appropriate (see section 6.4.3 above). [IFRS 9.B6.5.11].

The cumulative change in the fair value of the forward contract is £85,000, while the fair value of the cumulative change in expected future cash flows on the hedged item is £100,000. Ineffectiveness is not recognised in the financial statements because the cumulative change in the fair value of the hedged cash flows exceeds the cumulative change in the value of the hedging instrument. The whole of the fair value change in the forward contract would be recognised in other comprehensive income.

	December 20X2	£'000	£'000
Dr	Other comprehensive income	85	
	Cr Forward contract		85

Illustration 7-4: Cash flow hedge of commodity risk component in anticipated foreign currency commodity purchase

On 31 Dec 20X2, Company A, which has the euro as its functional currency, hedges the highly probable anticipated purchase of 50 tonnes of aluminium on 31 March 20X3 by buying 50 tonnes of aluminium futures on the LME. The futures are net settled in cash, determined as the difference between the LME future spot price of 50 tonnes of aluminium and US\$1.2m. Although A's aluminium purchase price is determined in US\$, A does not wish to eliminate the associated foreign currency risk as it expects to have sufficient US\$ funds available from anticipated US\$ sales also in March 20X3. Given the market structure in which A purchases the aluminium, A has identified the US\$ LME aluminium price as an eligible risk component in the highly probable anticipated purchase of aluminium (see section 2.2.3.B and 2.2.5 above). [IFRS 9.6.3.7(a)].

A designates the futures contract as the hedging instrument in a cash flow hedge of changes in the LME US\$ aluminium price risk component of the anticipated purchases. A determines that the hedge effectiveness requirements and the other hedge accounting criteria are met. In fact, as the hedged risk component matches exactly the underlying in the hedging futures, no major sources of ineffectiveness are anticipated. [IFRS 9.B6.3.11].

At the 31 January 20X3, the US\$ LME aluminium price has increased compared to the price at 31 December 20X0, and the euro/US\$ foreign currency rate is 1:1.07.

As a result, the cumulative change in present value of the expected cash outflow from A's anticipated purchase of aluminium due to changes in the US\$ LME price is an increase of US\$0.1m. The fair value of the hedging futures contracts is US\$0.1m positive. Other changes in A's anticipated purchase price for the 50 tonnes of aluminium are not considered within the hedge relationship, as hedge accounting is restricted to changes in the eligible risk component, in this case the US\$ LME aluminium price. [IFRS 9.B6.3.11]. Hence the hedge is still determined to meet the hedge effectiveness criteria.

A undertakes the cumulative 'lower of' accounting in the euro, its functional currency, translating both the cumulative change in present value of the expected cash inflow from A's anticipated purchase of aluminium and the cumulative change in fair value of the hedging futures contracts at the prevailing foreign currency rate.

Accordingly, for hedge accounting purposes, both the cumulative change in the fair value of the futures contracts and the present value of the change in expected cash inflow from A's anticipated purchase of aluminium due to changes in the US\$ LME price are €0.093m (= US\$0.1m / 1.07) therefore the hedge is perfectly effective and no ineffectiveness should be recorded, the whole of the fair value change in the futures contract is recognised in other comprehensive income. [IFRS 9.6.5.11(a)].

January 20X3		€'000	€'000
Dr	Futures contracts	93	
	Cr Other comprehensive income		93

Illustration 7-5: Cash flow hedge of a floating rate liability

Company A has a floating rate liability of £1 million with five years remaining to maturity. It enters into a five year pay-fixed, receive-floating interest rate swap with the same principal terms to hedge the exposure to variable cash flow payments on the floating rate liability attributable to interest rate risk.

At inception, the swap's fair value is £nil. Subsequently, there is an increase of £49,000 which consists of a change of £50,000 resulting from an increase in market interest rates and a change of minus £1,000 resulting from an increase in the credit risk of the swap counterparty. There is no change in the fair value of the floating rate liability, but the fair value (present value) of the future cash flows needed to offset the exposure to variable interest cash flows on the liability increases by £50,000.

Even if A determines that the hedge of interest rate risk meets the hedge effectiveness requirements (which is quite likely based on the fact pattern), it is not fully effective if part of the change in the fair value of the derivative is due to the counterparty's credit risk (see section 7.4.9 below). The accounting will be to credit the effective portion of the swap's fair value change, £49,000, to other comprehensive income. There is no debit to profit or loss for the change in fair value of the swap attributable to the deterioration in the credit quality of the swap counterparty because the cumulative change in the present value of the future cash flows needed to offset the exposure to variable interest cash flows on the hedged item, £50,000, exceeds the cumulative change in value of the hedging instrument, £49,000.

Alternatively, if the fair value of the swap increased to £51,000 of which £50,000 results from the increase in market interest rates and £1,000 from a decrease in the swap counterparty's credit risk, there would be a credit to profit or loss of £1,000 for the change in the swap's fair value attributable to the improvement in the counterparty's credit quality. This is because the cumulative change in the value of the hedging instrument, £51,000, exceeds the cumulative change in the present value of the future cash flows needed to offset the exposure to variable interest cash flows on the hedged item, £50,000. The difference of £1,000 represents the ineffectiveness attributable to the swap and is recognised in profit or loss. [IAS 39.F.5.2].

The above example illustrates that measurement of hedge ineffectiveness differs for a cash flow hedge when compared to a fair value hedge. In a cash flow hedge, if the fair value of the derivative increases by £10 and the present value of the hedged expected cash flows change by only £8, the £2 difference is recognised in profit or loss (as would be the case for a fair value hedge). However, in a cash flow hedge, if the present value of the hedged expected cash flows changes by £10, but the fair value of the derivative changes by only £8, this £2 of hedge ineffectiveness is not recognised in profit or loss (which would not be the case for a fair value hedge).

Because of this, an entity might consider deliberately under-hedging an exposure in a cash flow hedge. It might do this by targeting an offset of, say, 85% to 90%, however, whilst it still might be possible to demonstrate the existence of an economic relationship for such a designation (see section 6.4.1 above), it is unlikely to meet the hedge ratio requirements (as it seems the hedge ratio was established to avoid recognising ineffectiveness in a cash flow hedge) and so would most likely be precluded (see section 6.4.3 above). [IFRS 9.B6.4.11(a)].

7.2.2 Reclassification of gains and losses recognised in cash flow hedge reserve from OCI to profit or loss

The amount that has been accumulated in the cash flow hedge reserve in accordance with section 7.2.1 above shall be accounted for as follows:

- (a) If a hedged forecast transaction subsequently results in the recognition of a non-financial asset or liability, or a hedged forecast transaction for a non-financial asset or liability becomes a firm commitment for which fair value hedge accounting is applied, the entity shall remove that amount from the cash flow hedge reserve and include it directly in the initial cost or other carrying amount of the asset or liability. This is often referred to as a 'basis adjustment'. It is not a reclassification adjustment and hence it does not affect the statement of OCI for the period. Rather, it is presented as a separate item in the statement of changes in equity. [IAS 1.96, IFRS 18.B89].

And

- (b) For a hedged transaction in a cash flow hedge other than those covered in (a) above, that amount shall be reclassified from the cash flow hedge reserve to profit or loss as a reclassification adjustment in the same period(s) during which the hedged expected future cash flows affect profit or loss, e.g., in the periods that interest income or interest expense is recognised or when a forecast sale occurs.

[IFRS 9.6.5.11(d), IAS 1.92, IFRS 18.90].

The treatments for (a) above are shown in the following Illustration.

Illustration 7-6: Hedge of a firm commitment to acquire equipment

Consider a variation of the situation in Illustration 7-2 in section 7.1.2 above whereby Company X has chosen to treat all hedges of foreign currency risk associated with firm commitments as cash flow hedges, rather than as fair value hedges, as permitted by the standard (see section 5.2.2 above). Otherwise, the underlying facts and assumptions are the same. The accounting entries made at the end of March 20X2 have not been reflected here (as they were in Illustration 7-2) because they are not relevant to the issue being illustrated.

The journal entries to record this hedging relationship would be as follows:

January 20X2

No entries are required as the firm commitment is unrecognised, the forward contract is recognised but has a zero fair value and no cash is paid or received.

July 20X2		€	€
Dr	Forward contract	50	
	Cr Other comprehensive income (cash flow hedge reserve)		50

To recognise the change in fair value of the forward contract and, because no ineffectiveness arises, the whole of this change is recognised in other comprehensive income.

		€	€
Dr	Cash	50	
	Cr Forward contract		50

To record the settlement of the forward contract at its fair value.

		€	€
Dr	Machinery	950	
	Cr Cash		950

To record the settlement of the firm commitment at the contracted price of US\$1,000 at the spot rate of US\$1:€0.95.

		€	€
Dr	Other comprehensive income (cash flow hedge reserve)	50	
	Cr Machinery		50

To remove the gain recognised in other comprehensive income (cash flow hedge reserve) and adjust the carrying amount of the machinery that results from the hedged transaction by this amount. This is not a reclassification adjustment as per IAS 1 *Presentation of Financial Statements*²² and so does not appear in other comprehensive income for the period but is presented as a separate item in the statement of changes in equity. [IFRS 9.6.5.11(d)(i), IAS 1.96].

In summary, the result of these accounting entries is as follows:

	€	€
Dr Machinery	900	
Cr Cash		900

Which again reflects the starting presumption, i.e., that X had effectively fixed the purchase price of its machine at €900.

In applying treatment (b) above to hedged items that are not forecast transactions that subsequently result in the recognition of a non-financial asset or liability, or a hedged forecast transaction for a non-financial asset or liability becomes a firm commitment for which fair value hedge accounting is applied, an appropriate reclassification method must be applied. When instruments such as conventional interest rate swaps with a zero fair value on designation are used as a hedging instrument in a cash flow hedge, it is common for entities to recognise net interest income or expense on the hedging instrument directly in profit or loss on an accrual basis to meet the requirements of treatment (b) above. Other changes in fair value of the hedging instrument (i.e., the 'clean value' or fair value excluding accrued interest) are recognised in other comprehensive income, subject to the 'lower of' requirements (see section 7.2.1 above). Such an approach avoids the need to reclassify from cash flow hedge reserve to profit or loss the net interest as the hedged item impacts profit or loss. However, care must be taken to ensure the portion of the gain or loss on the hedging instrument that is recognised in the cash flow hedge reserve appropriately excludes ineffectiveness, which must be recognised in profit or loss. The hedging derivative would still be recognised in the statement of financial position at the full fair value.

Although not clearly stated in IFRS 9, it is implied that the reclassification from the cash flow hedge reserve to profit or loss gain or loss is likely to be recognised in the same line item in profit or loss as the hedged transaction, to reflect the offsetting effect of hedge accounting (see Chapter 50). [IFRS 9.6.5.11(d)].

If a hedge of a foreign currency forecast intragroup transaction qualifies for hedge accounting (see section 4.3.2 above), any gain or loss that is recognised in other comprehensive income must be reclassified from cash flow hedge reserve to profit or loss in the same period(s) during which the foreign currency risk of the hedged transaction affects consolidated profit or loss. [IFRS 9.B6.3.6]. In order for the consolidated profit or loss to be affected by a foreign currency forecast intragroup transaction, an associated external forecast transaction must also exist. Accordingly, that external transaction also drives the timing of recycling of the effective portion of the hedge relationship.

Guidance is provided on the accounting for the amount that has been accumulated in the cash flow hedge reserve on discontinuation of hedge accounting (see section 8.3.2 below). [IFRS 9.6.5.12].

7.2.3 Recycling for a hedge of foreign currency monetary items

It was stated in section 5.2.3 above that using a forward foreign currency contract to hedge a foreign currency payable or receivable could be treated either as a fair value hedge, or a cash flow hedge. In a fair value hedge, the gain or loss on remeasurement of both the forward contract and the hedged item are recognised immediately in profit or loss. Even if the forward foreign currency risk was the designated hedged risk, then ineffectiveness would arise from changes in the forward points, as the retranslation of the foreign currency payable or receivable is restricted to the IAS 21 spot revaluation (see section 7.1.1 above). [IFRS 9.B6.2.3].

22 IFRS 18 Presentation and Disclosure in Financial Statements, which supersedes IAS 1 for reporting periods beginning on or after 1 January 2027 (with earlier application permitted) was issued by the IASB in April 2024. See Chapter 4 for further details on the new concepts and requirements of IFRS 18.

However, in a cash flow hedge of the forward foreign currency risk, the cumulative gain or loss on remeasuring the forward contract is recognised in the cash flow hedge reserve (assuming no sources of ineffectiveness) and reclassified from the cash flow hedge reserve to profit or loss when the payable or receivable affects profit or loss (see section 7.2.2 above). Because the payable or receivable is remeasured continuously in respect of changes in foreign currency rates per IAS 21, there is a requirement for the gain or loss on the forward contract to be reclassified from the cash flow hedge reserve to profit or loss as the payable or receivable is remeasured, not when the payment occurs. There is variation in practice as to the method used to facilitate the reclassification over the period the payable or receivable affects profit or loss (see Illustration 7-18 in section 7.4.7 below).

The forward element of a forward contract can be excluded from a designated fair value or cash flow hedge relationship (designation of the spot exchange risk only - see section 3.6.5 above). In that case any fair value changes attributable to the forward element are recognised in other comprehensive income if accounted for as costs of hedging (see sections 7.4.7 and 7.5.2 below). [IFRS 9.6.5.16].

7.2.4 Cash flow hedges within subsidiaries on acquisition or disposal

Where a reporting entity acquires a subsidiary that is applying cash flow hedge accounting, additional considerations arise. In applying the acquisition method of accounting in its consolidated financial statements, the reporting entity does not inherit the subsidiary's existing cash flow hedge reserve, since this clearly represents cumulative pre-acquisition gains and losses (see Chapter 10). This has implications for the assessment of hedge effectiveness and the measurement of ineffectiveness because, so far as the group is concerned, it has effectively started a new hedge relationship with a hedging instrument that is likely to have a non-zero fair value (see section 6.3.1 above and section 7.4.3 below). Where a subsidiary is acquired as part of a transaction under common control and the acquisition method of accounting is not applied the situation is different (see Chapter 11).

The standard does not address the situation when it is anticipated that a subsidiary will be disposed of. In November 2016, the IFRS IC discussed the issue of whether a group must discontinue hedge accounting in the consolidated financial statements where the group applies cash flow hedge accounting to forecast transactions that are anticipated in a subsidiary after the expected date of disposal of that subsidiary. The IFRS IC were of the tentative view that the assessment of a qualifying hedging relationship must be performed from the group's perspective based on whether the transaction is highly probable and could affect the group's profit or loss. Given that the forecast transactions are expected to occur only after the expected date of disposal of the subsidiary, these transactions are no longer expected to occur from the group's perspective as soon as the subsidiary is classified as held for sale. According to the IFRS IC's tentative view the forecast transactions would no longer be eligible hedged items and the group would discontinue hedge accounting from the date the subsidiary is classified as held for sale.²³ The IFRS IC suggested that outreach would be helpful to understand if diverse accounting is currently applied in practice and is likely to be an issue to be considered in the Post Implementation Review of the IFRS 9 hedge accounting guidance. If the IFRS IC's view is confirmed, existing accounting policies might need to be changed retrospectively, although this has still not happened at the time of writing.

7.3 Accounting for hedges of a net investment in a foreign operation

Hedges of a net investment in a foreign operation (see section 5.3 above), including a hedge of a monetary item that is accounted for as part of the net investment (see section 5.3.2 above and Chapter 16), shall be accounted for similarly to cash flow hedges:

- The portion of the gain or loss on the hedging instrument that is determined to be an effective hedge must be recognised in other comprehensive income and (as clarified by IFRIC 16) included with the foreign exchange differences arising on translation of the results and financial position of the foreign operation. [IFRIC 16.3].
- And
- The ineffective portion shall be recognised in profit or loss. [IFRS 9.6.5.13].

²³ [IFRIC Update](#), November 2016, available on the IFRS Foundation's website.

Accordingly, as a result of accounting for hedges of a net investment there is no change to the usual IAS 21 requirement to retranslate the net investment at the closing spot rate (see Chapter 16). [IAS 21.39]. Consequently, as for cash flow hedge accounting, accounting for a net investment hedge only has the potential to change the accounting for the hedging instrument and only to the extent of the effective portion. The cumulative gain or loss on the hedging instrument relating to the effective portion of the hedge that has been accumulated in the foreign currency translation reserve shall be reclassified from equity to profit or loss as a reclassification adjustment on disposal or, in certain circumstances, partial disposal of the foreign operation in accordance with IAS 21 (see Chapter 16). [IFRS 9.6.5.14].

The meaning of 'similarly to cash flow hedges' is not immediately clear and has been the subject of some debate. It is readily understood that the portion of the gain or loss on the hedging derivative that is determined to be an effective hedge must be recognised in other comprehensive income (as it would for a cash flow hedge). However, the wording in the standard also seems to indicate that ineffectiveness must be measured in the same way as for cash flow hedges, i.e., no ineffectiveness is recognised in profit or loss if the gain or loss on the hedging instrument is less, in absolute terms, than the gain or loss on the hedged item (see section 7.2.1 above). This is despite the fact that there appears to be no good reason why ineffectiveness is not also recognised in profit or loss if the gain or loss on the hedging instrument is less, in absolute terms, than the gain or loss on the hedged item. This is different to the accounting for net investment hedges under US GAAP,²⁴ for which it is clear that ineffectiveness must be recognised in profit or loss for under-hedges as well as over-hedges.

In its March 2016 meeting, the IFRS IC discussed this issue. The IFRS IC concluded that the guidance in IFRS 9 is sufficiently clear and would require an entity to apply the lower of test for net investment hedges. One of the arguments put forward was that the application of the lower of test in determining the effective portion of the gains or losses arising from the hedging instrument when accounting for net investment hedges, avoids the recycling of exchange differences arising from the hedged item that have been recognised in other comprehensive income before the disposal of the foreign operation. Such an outcome would be consistent with the requirements of IAS 21.²⁵

Whilst the above accounting might appear relatively straight forward at first consideration, a number of additional complexities arise in the accounting for net investment hedges. The complexity is largely driven by the requirement to apply guidance written for a cash flow hedge to a situation where no cash flow arises, and the accounting for net investments in foreign operations within complex groups. These are further considered in the following sections. An overview of the various hedge designation alternatives for net investment hedges is also provided in section 7.3.4 below.

7.3.1 Identifying the effective portion in a net investment hedge

In accounting for a hedge of a net investment, IFRS 9 requires that the portion of the gain or loss on the hedging instrument that is determined to be an effective hedge must be recognised in other comprehensive income. [IFRS 9.6.5.13]. IFRIC 16 provides some helpful guidance in calculating the effective portion of the gain or loss on the hedging instrument.

As set out in section 5.3.1 above, IFRIC 16 explains that the hedged risk in a net investment hedge is defined by reference to the functional currency of a parent of the foreign operation that is the subject of the hedge. The cumulative gain or loss on the hedging instrument that is determined to be effective is the change in value of the hedging instrument in respect of foreign exchange risk, this must also be computed by reference to the functional currency of this parent entity. [IFRIC 16.15].

Depending on where the hedging instrument is held, in the absence of hedge accounting the total change in its value might be recognised in profit or loss, in other comprehensive income, or both (see Illustration 7-8 below). The interpretation states that the calculation of the effective portion is not affected by where the change in value of the hedging instrument would be recognised. In applying hedge accounting, the total effective portion of the change must be included in other comprehensive income. [IFRIC 16.15].

²⁴ ASC 815-35-35-1 through 35-26 (formerly, Statement 133 Implementation Issue H8, *Foreign Currency Hedges: Measuring the Amount of Ineffectiveness in a Net Investment Hedge*).

²⁵ [IFRIC Update](#), March 2016, available on the IFRS Foundation's website.

Illustration 7-7: Identification of the effective portion in a net investment hedge (1)

Consider the situation outlined in Illustration 5-3 above (see section 5.3.1 above). In summary, Company P is the ultimate parent entity of a group and presents its consolidated financial statements in its functional currency of the euro. It has two direct wholly owned subsidiaries, Company A whose functional currency is Japanese yen and Company B whose functional currency is sterling. B has a wholly owned subsidiary, Company C, whose functional currency is US dollars. P's net investment in A is ¥400,000 million. P's net investment in B is £500 million including the equivalent of £159 million representing B's net investment in C of US\$300 million. Also assume in this example that A has external borrowings of US\$300 million and that A's borrowings are designated in a hedge of the €/US\$ spot risk associated with P's net investment in C. In the absence of hedge accounting, the total US\$/€ foreign exchange difference on A's US\$300 million external borrowing would be recognised in P's consolidated financial statements as follows: [IFRIC 16.AG5]

- US\$/¥ spot foreign exchange rate change, translated to euro, in profit or loss
- And
- ¥/€ spot foreign exchange rate change in other comprehensive income

The fact that gain or loss on the hedging instrument is split between profit or loss and OCI does not affect the calculation of the effective portion in applying paragraph 6.5.13 of IFRS 9.

The cumulative gain or loss on the hedging instrument that is determined to be effective is computed by reference to the functional currency of P, the hedging parent, which is euro. [IFRIC 16.15]. Hence, according to the guidance, all of the €/US\$ foreign exchange difference on A's US\$300 million external borrowing would, after the application of hedge accounting, be recognised in other comprehensive income and be included in the foreign currency translation reserve relating to C.

The guidance says this is because the change in value of both the hedging instrument and the hedged item are computed by reference to the functional currency of P (euro) against the functional currency of C (US dollars). [IFRIC 16.AG4, IFRIC 16.AG7].

IFRIC 16 doesn't include a worked example. We have simplified the illustration by only revaluing the US\$ liability at year end and assumed the following spot exchange rates:

	JPY:US\$	US\$:Euro	JPY:Euro
1/1/20X0	125.0	1.2	150.0
31/12/20X0	108.0	1.3	140.4

Without hedge accounting, the revaluation entries on 31/12/20X0 relating just to the hedging instrument held by A and P's investment in C would be:

	€m	€m
Dr US\$ liability	36.32	
Cr Profit or loss		36.32

To revalue the US\$300m liability in A in profit or loss, translated into euros ((US\$300m × 125) - (US\$300m × 108) = JPY5,100m) ÷ 140.4). [IAS 21.39(b)].

Dr OCI	17.09	
Cr US\$ liability		17.09

To revalue A's US\$300m liability from yen to euros, through OCI (US\$300 × 125 ÷ 150) - (US\$300 × 125 ÷ 140.4) as part of the revaluation of P's opening net investment in A from yen to euros. [IAS 21.39(a)].

Dr OCI	19.23	
Cr Net assets of C		19.23

To revalue P's opening US\$300m net investment in C from US\$ into euros ((US\$300m ÷ 1.2) - (US\$300m ÷ 1.3)). [IAS 21.39(a)].

The hedge accounting entries would simply be to reverse the first two profit or loss and OCI entries in order to offset the third:

Dr Profit or loss	36.32	
Cr OCI for yen/euro revaluation		17.09
Cr OCI for US\$/euro revaluation		19.23

Illustration 7-8: Identification of the effective portion in a net investment hedge (2)

Using the same fact pattern as in Illustration 7-7 above, except, P designated its own US\$ denominated borrowings in a hedge of the spot foreign exchange exposure (£/US\$) between B and C, only the £/US\$ part of the change in the value of the borrowings (the effective portion of the hedging instrument) would be included in P's foreign currency translation reserve relating to C. The remainder of the change (equivalent to the £/€ change on £159 million) would be included in P's consolidated profit or loss. [IFRIC 16.AG12].

The calculation of the effective portion is not affected by whether the hedging instrument is a derivative or a non-derivative instrument or by the method of consolidation. [IFRIC 16.15]. Hence whether the direct or step-by-step method of consolidation is applied, the effective portion will be calculated in the same way (see Chapter 16). It should be noted however that the method of consolidation can result in a potential difference in the accounting outcome on disposal of a foreign operation (see section 8.3.8 below).

7.3.2 Non-derivative liabilities hedging a net investment

A foreign currency denominated non-derivative financial liability, such as a borrowing, can be used as the hedging instrument in a hedge of a net investment in a foreign operation (see section 3.3.1 above). [IFRIC 16.14]. This can be seen as purely an 'accounting' hedge, i.e., the retranslation gain or loss on the borrowing (an accounting entry representing a part of its change in fair value that is accounted for on a continuous basis) can offset the retranslation gain or loss on the net investment (another accounting entry). In fact, if the liability is:

- Denominated in the same currency as the functional currency of the hedged net investment
 - Held by an entity with the same functional currency as the parent by which the hedged risk is defined
 - Has an amortised cost that is lower than the net investment in the foreign operation
- And
- Is designated appropriately

Then the hedge is likely to be perfectly effective in terms of the offsetting retranslation gains and losses on the liability and the hedged proportion of the net investment.

If a borrowing or similar liability is denominated in a different currency to the functional currency of the net investment, it might still be possible to designate it as the hedging instrument. However, it will need to be demonstrated that the two currencies are sufficiently correlated so that the hedging instrument is expected to result in offsetting gains and losses over the period that the hedge is designated, i.e., an economic relationship exists (see section 6.4.1 above). This might be the case if the two currencies are formally pegged or otherwise linked to one another or if the relevant exchange rates move in tandem because of, say, similarities in the underlying economies.

Even if such a hedge meets the hedge effectiveness requirements (see section 6.4 above), it is likely to result in some ineffectiveness. Under US GAAP it is suggested that the retranslation gains and losses on the actual instrument must be compared to those on a hypothetical non-derivative (e.g., a borrowing in the correct currency) with any difference recognised in profit or loss.²⁶ This approach will normally be acceptable under IFRS 9, if applied in conjunction with the accounting requirements for net investment hedges (see section 7.3 above).

For hedges of foreign currency risk, the foreign currency risk component of a non-derivative financial instrument is determined in accordance with IAS 21. [IFRS 9.B6.2.3]. Therefore, when designating a foreign currency denominated non-derivative financial liability as the hedging instrument in a hedge of a net investment, it is only possible to designate the spot foreign exchange risk, and not a forward foreign exchange risk (see section 7.3.4 below). [IFRIC 16.AG2].

26 ASC 815-35-35-1 to 35-26 (formerly, Statement 133 Implementation Issue H8, *Foreign Currency Hedges: Measuring the Amount of Ineffectiveness in a Net Investment Hedge*).

7.3.3 Derivatives hedging a net investment

It is clear that a derivative instrument may be designated as the hedging instrument in a hedge of a net investment. [IFRIC 16.14]. What is harder to determine is how various types of derivatives might be designated in a hedge of a net investment in order that the hedge relationship meets the usual hedge accounting criteria, and how the relationship must be accounted for. For example:

- Is it possible to designate the forward foreign currency risk as the hedged risk in a net investment hedge?
- How should the hedged risk in the net investment be represented for ineffectiveness measurement purposes when the hedging instrument is a derivative?
- What is the accounting treatment for any excluded portions of a derivative hedging instrument in a net investment hedge?

These questions will be considered in the remainder of this section.

In the application guidance to IFRIC 16, it is noted that if the hedging instrument is a forward contract, then it is possible to designate a forward foreign currency risk as the hedged risk in a hedge of a net investment (see section 3.6.5 above). [IFRIC 16.AG2]. Forward foreign currency risk must therefore be deemed to exist within the net investment. If the forward foreign currency risk is designated for a net investment hedge, then the entire change in fair value of the hedging instrument (including changes in the forward element) must be included in the calculation of the portion of the gain or loss on the hedging instrument that is determined to be an effective hedge. [IFRS 9.6.5.13]. This could be achieved by using a hypothetical derivative that is also a forward foreign contract (see sections 7.3.4 and 7.4.4 below).

Like forward contracts, cross-currency interest rate swaps are sometimes used as hedging instruments in net investment hedges. It is often said that fixed-for-fixed cross-currency swaps are essentially a series of forward contracts and so arguably the treatment for forwards is equally applicable to cross-currency swaps. Therefore, it will also be possible for a fixed-for fixed cross-currency swap to be a good representation of the forward foreign currency risk in a net investment hedge (see sections 7.3.3.B and 7.3.4 below).

There is no reason why an option contract, that is not a written option, cannot be designated as the hedging instrument in a hedge of a net investment (see section 3.2.2 above). In fact, such a hedge is included as an example in the IFRS 9 application guidance. [IFRS 9.B6.5.29(b)]. However, it will most likely be helpful to designate only the change in intrinsic value of the option as the hedging instrument, as the time value does not exist in the hedged item (see section 7.5.1 below).

It is also possible to designate only the spot foreign currency risk associated with a derivative hedging instrument in a net investment hedge, thereby excluding other elements (e.g., the forward element) from the hedge relationship. [IFRS 9.6.2.4(b)]. In that case the hypothetical derivative would be a spot foreign currency contract.

Even when only spot risk is hedged, there is a requirement to consider the time value of money when measuring ineffectiveness (see sections 7.4.2 and 7.4.7 below). However, in the case of a hedge of a net investment, for which there are no cash flows or maturity date with respect to the hedged item, the concept of discounting the spot element back from the date the hedged item is expected to occur has no relevance. A net investment hedge is generally viewed as a hedge of an 'accounting' outcome, i.e., to offset the IAS 21 retranslation gain or loss on the net investment. In that sense the hedged item has already occurred and so the effect of the time value of money is zero (i.e., a discount factor of 1 is appropriate). Hence in the hedge of spot foreign currency risk within a net investment, and only in such a hedge, no discounting of the spot revaluation is required for the purposes of measuring ineffectiveness (see section 7.3.4 below).

Where such portions are excluded, they could be treated as costs of hedging (see section 7.5 below) or, alternatively, the excluded forward element of forwards and/or foreign currency basis spread could remain at fair value through profit or loss. [IFRS 9.6.5.16]. There is no choice of treatment for the excluded time value of options, as they must be treated as a cost of hedging. [IFRS 9.6.5.15].

If using a derivative in the hedge of a net investment of a foreign operation, as foreign currency basis spread cannot be assumed to exist in a non-derivative hedged item, ineffectiveness will occur unless the cost of hedging treatment is applied to the foreign currency basis spread (see section 7.4.8 below). This treatment for hedges of a net investment is discussed in more detail in section 7.5.2.A below.

Given the variety of hedging instruments and designation choices available in the hedge of a net investment and also considering the limited specific guidance available within IFRS 9 on this topic, we provide more discussion in the rest of this section, focusing on the different hedging instruments.

Additional application guidance is provided in section 7.3.4 below, illustrating the different designation approaches in the hedge of a net investment and the associated accounting consequences.

7.3.3.A Forward currency contracts hedging a net investment

It is very common for forward currency contracts to be used as the hedging instrument in a hedge of a net investment and, as noted above, it is possible to designate a forward foreign currency risk for such a hedge (see section 7.3.3 above). [IFRIC 16.AG2]. In that case, the hedged foreign currency risk in the net investment hedge would ordinarily be represented by a hypothetical forward foreign currency contract.

If on the other hand the spot risk is designated (i.e., the hedged foreign currency risk in the net investment hedge is represented by a hypothetical spot foreign currency exposure), the costs of hedging guidance could be applied to the excluded portion rather than fair value changes in the excluded portion being recognised immediately in profit or loss (see section 7.5 below).

Under either designation, the minimum amount of net investment required to match the hedging instrument would be an amount equal to the foreign currency leg of the forward currency contract (see section 7.3.4 below).

It is clear under IFRS 9 that foreign currency basis spread cannot be assumed to exist in a non-derivative hedged item (including a foreign currency net investment), hence this will be an additional source of ineffectiveness, unless foreign currency basis spread is excluded from the hedging instrument (see sections 7.4.8 and 7.5.3 below). [IFRS 9.B6.5.5].

7.3.3.B Cross-currency interest rate swaps hedging a net investment

Like forward contracts, cross-currency interest rate swap instruments are commonly used as hedging instruments in net investment hedges. However, the general suitability of a cross-currency swap as the hedging instrument in the hedge accounting of a net investment and what the appropriate hypothetical derivative would be for measuring ineffectiveness, depends very much on the type of cross-currency interest rate swap used.

At a conceptual level, it is easy to see that the changes in value of a cross-currency swap with two floating-rate legs are likely to offset the spot retranslation gains and losses of a net investment, provided the floating rate resets sufficiently frequently. Hence such a designation will most probably meet the requirement to demonstrate that an economic relationship exists, although some residual ineffectiveness is likely to occur from fair value changes in the most recently reset floating rate legs of the cross-currency swap and also from foreign currency basis spread (if not excluded from the hedge relationship (see sections 7.3.4, 7.4.8 and 7.5.2.A below)). With the transition from term IBOR rates to the use of daily compounding overnight risk-free rates as part of IBOR reform, ineffectiveness caused by floating legs will be significantly reduced (see the *Supplement: IBOR Reform*).

Although the forward element is not explicitly defined by the standard, it is explained that the difference between the forward rate and the spot rate (i.e., 'the forward element') represents the interest differential between the two currencies at inception (see section 3.6.5 above). [IFRS 9.BC6.424]. Accordingly, as the interest differential in a cross-currency swap with two floating-rate legs is not set at inception, it appears that it is not possible to designate the forward foreign currency risk for such a hedging instrument (see section 7.3.4 below).

It is also reasonably easy to see that a swap with one floating-rate leg and one fixed-rate leg could result in levels of ineffectiveness that would contradict the existence of an economic relationship between the hedged item and hedging instrument, which would preclude hedge accounting (see section 6.4.1 above). This is because the fair value of a swap with one floating-rate leg and one fixed-rate leg will change due to factors unrelated to changes in forward exchange rates.

As noted previously (see section 7.3.3 above), a fixed-for-fixed cross-currency swap is often viewed as a combination of a series of forward contracts, (i.e., each interest and principal fixed foreign currency cash flow and associated fixed functional currency cash flow is a forward contract, albeit based on a blended forward rate across the life of the instrument). Accordingly, it would make sense that designation of either the forward foreign currency risk or the spot foreign currency risk is permitted. This is well established in practice and is relatively uncontroversial. However, variation in practice does arise in how the spot and forward elements are identified when using a fixed-for-fixed cross-currency swap in the hedge of a net investment. This variation in practice is partly driven by the fact that IFRS 9 requires that net investment hedges shall be accounted for similarly to cash flow hedges. [IFRS 9.6.5.13]. This guidance, which requires the existence of cash flows within hedged items, therefore requires some interpretation when it is applied to hedged items for which no cash flows exist.

One alternative is to designate the fixed-for-fixed cross-currency swap, such that the amount of the hedged item would be equal to the sum of the undiscounted foreign currency interest and principal payments, (i.e., an amount higher than just the notional amount of the swap). This approach is consistent with a cash flow hedge view, since it best matches the cash flows on the swap, but arguably overstates the foreign exchange risk as it is based on undiscounted foreign currency exposures.

Another approach would be to designate the fixed-for-fixed cross-currency swap, such that the amount of the hedged item would equal just the undiscounted foreign currency principal payment (i.e., the notional amount of the swap). This approach is based on the view that the interest payments on the cross-currency swap economically represent the forward interest element within the swap, and so will not form part of the spot element. [IFRS 9.BC6.416].

How we see it

We believe it is acceptable to designate amounts equal to either the sum of a fixed-for-fixed cross-currency swap's undiscounted foreign currency interest and principal payments, or just its notional principal, as the hedged item in a net investment hedge.

Both views are explained further in Illustration 7-9 below.

Illustration 7-9: Hedge of a foreign currency net investment using a cross-currency swap

Entity P, functional currency euro, has a £120m foreign currency net investment in Subsidiary S. S's functional currency is GBP. In order to hedge a proportion of the foreign currency EUR/GBP translation risk associated with P's net investment in S, P has transacted a 2 year fixed-for-fixed cross-currency swap as follows: a foreign currency leg with a notional amount of £100 million, paying 3% annually, and a functional currency leg with €110m notional, receiving 2.5% annually.

P chooses to designate the forward foreign currency risk in £106 million of the net investment (i.e., a proportion of the net investment is hedged by each foreign currency cash flow arising from the cross-currency swap, in this case the £100 million plus the two payments of interest of £3 million). The foreign currency risk for such a designated hedged item could be represented by a fixed-for-fixed cross-currency swap (this would be for both the hypothetical derivative used to measure the effective portion and the aligned hedging derivative if the costs of hedging guidance is applied to the cross-currency basis spread) (see sections 7.3.4, 7.4.4. and 7.5.2 below). If cost of hedging is not applied, then the changes in the fair value of the cross-currency swap due to cross-currency basis spreads would be recognised in profit or loss. [IFRS 9.B6.5.5].

If P were to choose to designate the spot foreign currency risk of the £106 million of net investment, only the undiscounted spot revaluation of the aggregate of the swap foreign currency notional and interest payments would form part of the hedge relationship (see section 3.6.5 above). As no sources of ineffectiveness exist in this fact pattern, other changes in the fair value of the cross-currency swap would form part of the cost of hedging for the forward element and cross-currency basis spreads, if cost of hedging accounting is applied. If cost of hedging is not applied, then the other changes in the fair value of the cross-currency swap would be recognised in profit or loss.

Alternatively, P could choose to designate the fixed-for-fixed cross-currency swap with a foreign currency notional amount of £100 million as a hedge of the forward foreign currency risk in a net investment of only £100 million. In that case, (similar to the designation of £106 million of net investment above) the foreign currency risk for such a designated hedged item could be represented by a fixed-for-fixed cross-currency swap (this would be for both the hypothetical derivative used to measure the effective portion and the aligned hedging derivative if the costs of hedging guidance is applied to the cross-currency basis spreads). If cost of hedging is not applied, then the changes in the fair value of the cross-currency swap due to cross-currency basis spreads would be recognised in profit or loss.

If P were to choose to designate the spot foreign currency risk only of the £100 million net investment, only the undiscounted spot revaluation of the swap foreign currency notional would form part of the hedge relationship. As no sources of ineffectiveness exist in this fact pattern, other changes in the cross-currency swap fair value will form part of the cost of hedging for the forward element and cross-currency basis spreads. If the cost of hedging guidance is not applied, then the other changes in fair value of the cross-currency swap would be recognised in profit or loss.

See section 7.3.4 below for a further illustration of the different designation possibilities.

It can be seen from the above illustrations that if there are no sources of ineffectiveness, then volatility in profit or loss from fair value changes in the hedging cross-currency swap can be eliminated under all designation alternatives if the cost of hedging guidance is also applied. However, given that volatility in profit or loss from changes in fair value due to cross-currency basis spreads can only be eliminated if the cost of hedging guidance is applied, it might be operationally simpler to hedge only the spot foreign currency risk, and apply the cost of hedging guidance to both the forward element and the cross-currency basis spreads (see section 7.5.3.A below). This will result in both being amortised to profit or loss on a systematic and rational basis. However, under a forward foreign currency risk designation, the forward element would remain in foreign currency reserve, until the net investment was disposed of (see section 8.3.8 below).

7.3.3.C Purchased options hedging a net investment

It is possible to designate the intrinsic value of a purchased option as the hedging instrument (i.e., its time value is excluded from the hedge relationship) (see section 3.6.4 above). Such a designation would require the costs of hedging treatment to be applied. The costs of hedging accounting would require changes in fair value of the excluded time value to be initially recorded in other comprehensive income to the extent it relates to the hedged item (see section 7.5.1 below).

As discussed in section 3.6.4 above, designating the entire purchased option as the hedging instrument is likely to result in high levels of ineffectiveness and could challenge the existence of an economic relationship (see section 6.4.1 above). This is because no offset will arise for changes in the time value of the purchased option, as the time value is not a component of the hedged net investment. [IFRS 9.B6.3.12].

7.3.4 Overview of alternatives for designation of a net investment hedge

As can be seen from the sections above there are a variety of different ways in which a net investment (NI) hedge can be designated. In order to compare and contrast the different outcomes for net investment hedge accounting, we set out below a high-level summary of some of the more common strategies for a net investment hedge. In the examples below within Figures 7-1, 7-2 and 7-3, for simplicity, we have assumed that there are no sources of ineffectiveness, including from foreign currency basis spreads. However, given that an assumption of no ineffectiveness from foreign currency basis spreads is an unlikely scenario, an indication of the effect of foreign currency basis spread is provided in the footnotes below the tables (also see section 7.4.8 below).

Figure 7-1: Designation of the spot element in a net investment hedge without application of costs of hedging

	Hedging instrument			
	Foreign currency issued debt	Foreign currency forward contract	Floating-floating cross-currency swap	Fixed-fixed cross-currency swap
Risk measure applied in identifying the designated portion of the hedging instrument and NI that is used to determine the effective portion of the hedge (the 'lower of assessment') (see section 7.3 above)	Undiscounted spot for NI and hedging instrument ⁽¹⁾	Undiscounted spot for NI and hedging instrument ⁽¹⁾	Undiscounted spot for NI and hedging instrument ⁽¹⁾	Undiscounted spot for NI and hedging instrument ⁽¹⁾

Minimum amount of NI required to match the hedging instrument	N/A	Foreign currency leg of foreign currency forward contract	Foreign currency principal of hedging swap	(a) Aggregate of foreign currency principal plus coupons of hedging swap Or (b) Foreign currency principal of hedging swap ⁽³⁾
Aligned instrument (cost of hedging) ⁽¹⁵⁾	N/A	Foreign currency forward contract	Floating-floating cross-currency swap ⁽¹³⁾	Fixed-fixed cross-currency swap
Accounting for NI (no change to IAS 21 requirements (see section 7.3 above))	N/A	Undiscounted spot to FX reserve	Undiscounted spot to FX reserve	Undiscounted spot to FX reserve ⁽⁴⁾
Accounting for changes in fair value of the hedging instrument ⁽¹⁵⁾	N/A	Undiscounted spot to FX reserve Residual changes in fair value to separate component of equity, amortised to P&L over the life of the foreign currency forward contract ⁽¹⁴⁾	Undiscounted spot to FX reserve Changes in fair value of aligned foreign currency basis to separate component of equity, and amortised to P&L over the life of the hedging swap Any residual fair value changes (e.g., once floating coupons are fixed) is taken to profit or loss ⁽¹³⁾	(a) Undiscounted spot on principal and coupons of hedging swap to FX reserve Or (b) Undiscounted spot on principal of hedging swap to FX reserve (a) and (b) residual changes in FV to separate component of equity, and amortised to P&L over the life of the hedging swap ⁽¹⁴⁾

Hedging instrument				
	Foreign currency issued debt	Foreign currency forward contract	Floating-floating cross-currency swap	Fixed-fixed cross-currency swap
Profit or loss profile after hedge accounting (14) (6)	N/A	Forward element amortised to P&L over the life of the FX forward	Floating legs recognised in P&L, including some fair value volatility from coupon fixings over time Cross-currency basis spread amortised to P&L over the life of the swap (13)	Fixed legs interest recognised in P&L over the life of the hedge
OCI profile after hedge accounting	N/A	Some volatility over the life of the hedge from forward element, but net nil on maturity of foreign currency forward contract	Some volatility over the life of the hedge from foreign currency basis spreads, but net nil on maturity of hedging swap	Some volatility over the life of the hedge from discounting of fixed legs, but net nil on maturity of hedging swap

- (1) In the hedge of spot foreign currency risk within a NI, and only in such a hedge, no discounting of the spot revaluation is required for the purposes of measuring ineffectiveness as the hedged item does not have any cash flows or maturity date to discount back from (see section 7.3.3 above).
- (2) Although in most cases the hypothetical derivative will take the same form as the hedging instrument (i.e., debt, foreign currency forward, foreign currency swap etc.) it is clear that the terms of the hypothetical derivative are based on the hedged item (NI in this case). Hence if there is a mismatch between the designated amount of NI and the hedging instrument, then ineffectiveness could arise as the hypothetical and actual hedging instrument will not be the same (see section 7.4.4 below).
- (3) As per 7.3.3.B.
- (4) The amounts in OCI will not be the same under designation a) and b). This is because the amount of designated NI is different under each designation, and so the amount of offset from the undiscounted spot revaluation of the designated NI will also be different.
- (5) Where the hedging instrument is a non-derivative, the foreign currency risk component of a non-derivative financial instrument is determined in accordance with IAS 21 (see section 7.3.2 above).
- (6) The above scenarios all assume no sources of ineffectiveness. Where sources of ineffectiveness do arise (e.g., insufficient NI is designated) some additional P&L volatility might arise, subject to the 'lower of assessment'.
- (7) Although the above assumes that foreign currency basis does not exist, in reality profit or loss volatility would also arise from changes in fair value in the hedging instrument due to foreign currency basis spreads (unless the costs of hedging treatment is applied) (see sections 7.4.8 and 7.5 below).
- (8) The amounts in P&L will not be the same under designation a) and b). This is because under designation a), in addition to the spot revaluation of the foreign currency principal being recognised in OCI, the undiscounted spot revaluation of the foreign currency coupons will also be recognised there rather than P&L. However, this additional spot revaluation will be offset in OCI by the additional amount of NI designated under designation a).
- (9) Designation of the forward element is not permitted when hedging with a non-derivative (see section 7.3.2 above). [IFRS 9.B6.2.3, IFRIC 16.AG2].
- (10) As the forward element has been designated, the risk management objective must be to hedge the forward foreign currency risk over the life of the hedging instrument - in that case it is appropriate to infer a forward date for the purposes of hedge accounting. [IFRIC 16.AG2].
- (11) As the forward element in a floating-floating cross-currency swap has not been locked in, this is not a hedge of a forward rate, hence there is no forward element to designate (see section 7.3.3.B above). [IFRS 9.6.2.4(b), IFRS 9.BC6.426].
- (12) There are no eligible cost of hedging within a non-derivative hedging instrument, so designation is not permitted (see section 7.5 below).

- (13) As the forward element in a floating-floating cross-currency swap has not been locked in, it is not possible to apply the costs of hedging guidance to a forward element - however the cost of hedging guidance is relevant for foreign currency basis (see sections 7.4.8 and 7.5.2 below).
- (14) Although the above assumes that foreign currency basis does not exist, it is possible to apply the costs of hedging guidance to foreign currency basis under this designation, in the same way as for the forward element.
- (15) Although when hedging NI it will be common for the aligned instrument to have the same terms as the hedging instrument, if there is insufficient NI and/or the hedging derivative did not have a zero fair value on designation, some differences will arise that could result in additional P&L volatility (see section 7.5.1.A below).

7.3.5 Combinations of derivative and non-derivative instruments hedging a net investment

It is not uncommon for entities to hedge their net investments using synthetic foreign currency debt instruments. For example, consider a parent with the euro as its functional currency that has a net investment in a Japanese subsidiary with yen as its functional currency. The parent might borrow in US dollars and enter into a pay-Japanese yen, receive-US dollar cross-currency interest rate swap. In this way the two instruments might be considered a synthetic Japanese yen borrowing, although they are required to be accounted for separately (see Chapter 42).

As noted in section 3.5 above, a combination of derivatives and non-derivatives may be viewed in combination and jointly designated as a hedging instrument. [IFRS 9.6.2.5]. However, all the hedging instruments must be clearly identified in the hedge documentation (see section 6.3 above). [IFRS 9.6.4.1(b)].

The European parent in the above fact pattern might wish to designate the spot rate only when hedging a net investment with a combination of derivatives and non-derivatives. Designation of the combination as hedging a forward rate is more problematic as the foreign currency risk component of a non-derivative financial instrument is restricted to the spot rate, in accordance with IAS 21 (see sections 3.3.1 and 7.3.4 above). [IFRS 9.6.2.3].

Another alternative could be to notionally decompose the cross-currency swap by introducing an interest bearing functional currency denominated leg and designating one part as a hedge of the borrowing and the other as a hedge of the net investment (see section 3.6.2 above).

7.3.6 Individual or separate financial statements

The discussion so far has concentrated on the accounting for a hedge of the foreign currency risk in a foreign operation in the parent's consolidated financial statements. However, all references to consolidated financial statements in the guidance on accounting for net investment hedges apply equally to standalone financial statements in which the net assets of a foreign operation are included. This will include financial statements in which investments in a foreign operation that is a joint venture, an associate or a branch are accounted for using the equity method. [IFRIC 16.2, IFRIC 16.7].

In a parent's individual or separate financial statements there is an accounting policy choice as to how the investment in the foreign operation is accounted for:

- As an asset measured at cost
 - As a financial asset in accordance with IFRS 9
- Or
- Using the equity method as described in IAS 28 *Investments in Associates and Joint Ventures* (see Chapter 12) [IAS 27.10]

So although not explicitly stated in IFRIC 16, it would also be possible to apply the guidance on net investment hedges in standalone financial statements in which investments in subsidiaries are accounted for using the equity method. [IFRS 9.6.5.2(c), IAS 21.44, IAS 27.10(c)].

Where net investment hedges have been designated in a parent's consolidated financial statements there is also the question of whether hedge accounting can be applied in that parent's individual or separate financial statements if the equity method is not applied. This question is only likely to arise where an eligible hedging instrument exists within the parent entity (e.g., the parent entity has foreign currency external borrowings which are designated as the hedging instrument in a net investment hedge in the consolidated financial statements).

In the reporting entity's individual or separate financial statements, if the accounting policy choice is to measure the investment either at cost or in accordance with IFRS 9, it is not accounted for as a net investment in a foreign operation and hence net investment hedge accounting is precluded. [IFRS 9.6.5.2(c), IAS 21.8]. This means a borrowing designated as the hedging instrument in a net investment hedge in the consolidated financial statements, could not be similarly designated in a net investment hedge for the purposes of the separate financial statements.

However, if hedge accounting is desirable, it could be possible to designate the borrowing as the hedging instrument in another type of hedge relationship.

How we see it

It would in our view be possible to designate the foreign currency risk in the carrying value of the foreign currency denominated investment in the parent entity's separate financial statements. Typically, this would be a fair value hedge of the foreign currency risk arising from the investment (see section 5.1 above). This will be an independent hedge relationship, separate from the net investment hedge in the consolidated financial statements. Therefore, all of the other hedge accounting criteria (including the documentation requirements) will need to be met for this hedge too. Of course, the effects of this hedge accounting will need to be reversed when preparing the group's consolidated financial statements (otherwise those financial statements will reflect as an asset or liability certain changes in the fair value of a parent's investment in its subsidiary which would be contrary to the general principles of IFRS 10 see Chapter 8).

7.4 Measuring ineffectiveness

7.4.1 General requirements

Hedge ineffectiveness is the extent to which the changes in the fair value or cash flows of the hedging instrument are greater or less than those on the hedged item. [IFRS 9.B6.4.1].

All hedge ineffectiveness is recognised in the profit or loss for fair value hedges (except where the hedged item is an equity instrument measured at fair value through OCI) (see section 7.1.1 above). For cash flow and net investment hedges ineffectiveness is recognised in the profit or loss to the extent that the cumulative change in the fair value or cash flows of the hedging instrument are greater than those on the hedged item (see sections 7.2.1 and 7.3 above). Accordingly, the measurement of ineffectiveness is an important aspect of IFRS 9. [IFRS 9.6.5.8, IFRS 9.6.5.11, IFRS 9.6.5.13].

Although, for many hedge relationships, it will be acceptable to undertake a qualitative assessment as to whether the hedge effectiveness requirements are met (see section 6.4 above) there is still a requirement to measure and record ineffectiveness appropriately within the financial statements. Other differences arise between assessing effectiveness for hedge qualification purposes and measuring ineffectiveness for the purposes of accounting for effective hedges. For example, in the hedge of foreign currency risk in a net investment the accounting for the net investment is restricted to the IAS 21 retranslation at the closing spot rate, but this is not the case in assessing effectiveness (see section 7.3 above).

In determining the ineffectiveness of a hedge relationship, it is important to closely follow the hedge designation. In particular it is necessary to determine the hedged risk, and whether any portions or proportions have been excluded from the hedged item (see sections 2.2 and 2.3 above) and/or the hedging instrument (see section 3.6 above). Hedge ineffectiveness only relates to those elements not excluded from the hedge relationship, and for the hedged item only, with respect to changes in the hedged risk, not the full price risk (see Illustration 7-4 in section 7.2.1 above). [IFRS 9.B6.3.11, IFRS 9.B6.4.1]. The initial designation and documentation of a hedge relationship is therefore very important and can in some cases significantly reduce the expected ineffectiveness levels from hedge relationships. However, it should be noted that not all sources of ineffectiveness can be eliminated via clever hedge designation. All sources of ineffectiveness must be documented as part of the hedge documentation. [IFRS 9.6.4.1(b)].

The calculation of ineffectiveness compares the monetary amount of the change in fair value of the hedging instrument with the monetary amount of the change in fair value or cash flows of the hedged item or transactions attributable to the hedged risk, over the assessment period. This is illustrated by the following simplified example:

Illustration 7-10: Calculation of ineffectiveness

An entity issues fixed rate debt at par of £100, with annual fixed interest of 3%. On the same day, the entity designates an existing interest rate swap in a fair value hedge relationship with the issued debt, for changes in SONIA. The existing swap has a notional of £100, a receive leg of 2.5% annually and a floating leg paying a compounded SONIA rate every 6 months. At the first quarterly reporting period after designation, (i.e., prior to settlement of any coupons on the debt or interest rate swap) the effectiveness would be calculated as follows:

	Hedged item (issued debt)	Hedging instrument (existing swap)
Fair value on initial designation	£100 CR	£4.5 CR
Fair value on first reporting date	£107 CR	£2.4 DR
Change in fair value of the hedging instrument over the assessment period		£6.9 gain
Change in fair value of the hedged item attributable to the hedged risk over the assessment period	£7 loss	

Hedge ineffectiveness is calculated by comparing the £6.9 gain on the hedging instrument with £7 loss on the hedged item over the assessment period.

Whilst it might be relatively obvious how to calculate the change in fair value or cash flows of a hedged item with fixed flows for changes in the hedged risk since designation (typically a fair value hedge) (see section 5.1 above), it is less obvious how this might be achieved where the hedged flows are not fixed, in particular, as hedged items with variable flows do not tend to attract fair value risk. This is discussed in more detail in sections 7.4.4 and 7.4.6 below.

7.4.2 The time value of money

Entities must consider the time value of money when measuring hedge ineffectiveness. This means that an entity must determine the value of the hedged item on a present value basis (thereby including the effect of the time value of money). [IFRS 9.B6.5.4]. The inclusion of the words “the changes in the fair value or cash flows” in the definition of ineffectiveness is unhelpful (see section 7.4.1 above), but the need for consideration of the time value of money is clear based on the noted application guidance of IFRS 9. In valuation practice, the effect of the time value of money is also included when measuring the fair value of financial instruments. Consequently, it is logical to apply the same principle to the hedged item as well.

It is possible to designate a spot element of a hedged item if it can be determined to be an eligible risk component (see section 2.2 above). Whilst a spot designation is relatively commonplace for both foreign currency and commodity risk, the need to consider the time value of money for effectiveness purposes for spot designations has been a matter of some debate in the past. The IAS 39 Implementation Guidance contains an example in which an entity designates changes in the spot element only. The example indicates that the time value of money is still relevant for the measurement of ineffectiveness even when the spot element is designated in a hedge relationship. Although the example is based on the IAS 39 Implementation Guidance it is still relevant under IFRS 9 (see section 7.4.7 below). [IAS 39.F.5.6].

How we see it

IFRS 9 requires that the time value of money is considered when measuring ineffectiveness. Accordingly, when measuring ineffectiveness in the hedge of changes in spot risk this too must be undertaken on a present value basis, which means the spot rates used will need to be discounted from the date of the hedged cash flow.

There are a couple of exceptions to the requirement to use discounted spot when measuring ineffectiveness, such that the normal IAS 21 revaluation requirements are applied; in the hedge of foreign currency risk by a non-derivative financial instrument, and in the hedge of a net investment in a foreign operation, whereby the net investment and (if applicable) the non-derivative financial instrument are retranslated at the closing rate (an undiscounted spot rate) (see sections 3.3.1 and 7.3 above).

Illustration 7-11 below simply demonstrates how ineffectiveness can arise when there are differences in the timing of hedged and hedging cash flows, even when only hedging changes in spot risk.

Illustration 7-11: Impact of time value of money when measuring ineffectiveness

A manufacturing company in India, having the Indian Rupee as its functional currency, is expecting forecast sales in USD. The company assesses sales of USD1 million per month for the next twelve months to be highly probable and wishes to hedge the related foreign currency exposure. The company also holds a borrowing of USD20 million with a bullet repayment in fourteen months' time. Instead of entering into foreign currency forward contracts, the company designates the US dollar borrowing as a hedging instrument in hedges of the spot risk of the monthly highly probable US dollar sales.

When measuring hedge ineffectiveness, the revaluation of the forecast sales for foreign currency spot risk would have to be made on a discounted basis (i.e., a present value calculation reflecting the time between the reporting date and the individual future cash flow dates), whereas the revaluation of the hedging instrument would not (as this follows the requirements of IAS 21) (see section 3.3.1 above). [IFRS 9.B6.2.3].

Similarly, if instead of using a US dollar borrowing as the hedging instrument, the entity transacted a forward foreign currency contract to sell USD12 million for Indian Rupee in 12 months' time, ineffectiveness will arise due to the differences in the timing of hedged and hedging cash flows. For the hedged cash flows, the revaluation for foreign currency spot risk would have to be a present value calculation reflecting the time between the reporting date and the individual future monthly cash flow dates. In the same way, to measure hedge effectiveness, the present value of the spot foreign currency revaluation of the hedging instrument would reflect the time value to the ultimate maturity of the forward contract, which is not the same as the timing of the hedged individual monthly forecast cash flows. The treatment of the excluded forward element of the forward contract is discussed further in section 7.5.2 below.

The requirement to calculate ineffectiveness on a present value basis intuitively makes sense in cases where the cash flows of the hedged item and hedging instrument are not aligned. It would seem inappropriate to have no ineffectiveness under a spot designation, for example in the situation described in section 3.3.1 above, where a 7-year financial liability denominated in a foreign currency is used as the hedging instrument for a 12 month forecast sale in that foreign currency. See Illustrations 7-17 and 7-18 in section 7.4.7 below for detailed examples of the accounting for hedge relationships where the foreign currency spot risk is designated.

7.4.3 Hedging using instruments with a non-zero fair value

There is no requirement for hedge accounting to be designated on initial recognition of either the hedged item or the hedging instrument. [IFRS 9.B6.5.28]. However, there is often a hidden danger when designating a derivative as a hedging instrument subsequent to its inception. For non-option derivatives, such as forwards or interest rate swaps, any fair value is likely to create 'noise' in measuring hedge ineffectiveness that might not be fully offset by changes in the hedged item, especially in the case of a cash flow hedge. This is because the derivative contains a 'financing' element (the initial fair value), gains and losses on which will not be replicated in the hedged item and therefore the hedge contains an inherent source of ineffectiveness. For example, if applying the hypothetical derivative method for measurement of ineffectiveness (see section 7.4.4 below) this financing element will be evident as the hypothetical derivative will be based on the prevailing market rates on designation, which will result in cash flows that differ from those of the actual now 'off market' derivative.

When hedging with an in the money option contract (i.e., it has positive intrinsic value), a similar issue arises. If applying the hypothetical derivatives method for measurement of ineffectiveness, any existing intrinsic value of the hedging option will not be replicated in the hypothetical derivative as it represents changes in the hedged risk in the period prior to the hedge designation and so is not relevant for the hedge relationship (see section 7.4.4 below).

Consequently, there is likely to be more ineffectiveness recognised and, in extremis, a quantitative assessment could be needed to demonstrate the existence of an economic relationship (see section 6.4.1 above). It depends on the circumstances whether hedge ineffectiveness arising from the financing element (or intrinsic value) on designation could have a magnitude that a qualitative assessment would not adequately capture. [IFRS 9.B6.4.15]. Only by coincidence will a derivative that was entered into previously still have a fair value that is zero, or close to zero, on the date of designation which would minimise this problem. In the case of a fair value hedge, it might be possible to designate a risk component that matches a non-option hedging instrument even though it has a non-zero fair value (see section 2.4.1 above).

This situation can not only arise when a derivative is designated or redesignated in a hedging relationship subsequent to its initial recognition, but also in a business combination (see section 6.3.1 above).

This same issue does not arise for hedged items that are designated after initial recognition, however difficulties can occur identifying eligible risk components (see section 2.4.1 above).

7.4.4 Hypothetical derivatives

A method commonly used in practice to calculate ineffectiveness of cash flow hedges (and net investment hedges) is the use of a so-called 'hypothetical derivative'. The method involves establishing a notional derivative that has terms that match the critical terms of the hedged exposure (normally an interest rate swap or forward contract with no unusual terms) and a zero fair value at inception of the hedging relationship. The fair value of the hypothetical derivative is then used as a proxy to measure the change in the value of the hedged item against which changes in value of the actual hedging instrument are compared to calculate ineffectiveness. The use of a hypothetical derivative is one possible way of determining the change in the value of the hedged item when measuring ineffectiveness. [IFRS 9.B6.5.5].

IFRS 9 is clear that a hypothetical derivative has to be a replication of the hedged item and not the 'perfect hedge'. Also, the standard makes clear that any different method for determining the change in the value of the hedged item would have to give the same outcome. Consequently, an entity cannot include features in the hypothetical derivative that only exist in the hedging instrument, but not in the hedged item.

[IFRS 9.B6.5.5]. Whilst this appears to be a logical requirement, it could have wider implications for cash flow hedges than many would have expected. An entity cannot simply assume no ineffectiveness for a cash flow hedge because the principal terms of the hedging instrument exactly match the principal terms of a hedged item, if there are differences in other features of the hedging instrument and the hedged item. For example, IFRS 13 requires an entity to reflect both the counterparty's credit risk and the entity's own credit risk when determining the fair value of a derivative. The same credit risk cannot be assumed in the hypothetical derivative. This difference in credit risk would result in some ineffectiveness (see sections 7.4.5 and 7.4.9 below).

It is possible to exclude the credit risk in the hedged item from the hedge relationship, for example by designating interest rate risk as the hedged risk (see section 2.2 above). This does not eliminate ineffectiveness from changes in the credit risk of the hedging derivative but prevents additional ineffectiveness from changes in the credit risk of the hedged item. (This assumes that credit risk is not of a magnitude such that it dominates the value changes of the hedged item (see section 6.4.2 above)).

Illustration 7-12 and Illustration 7-13 below provide simple examples of how an entity might establish and apply a hypothetical derivative for the calculation of ineffectiveness in a hedge relationship.

Illustration 7-12: Determination of a hypothetical derivative in a cash flow hedge of interest rate risk

Company X has purchased £200m of variable rate 5-year debt securities. The debt securities yield 1-month SONIA plus 100 basis points with coupons paid monthly. Company X wishes to mitigate cash flow variability from the debt securities by transacting a 5-year interest rate swap with £200m notional, receiving a fixed coupon of 2.0% quarterly and paying an overnight SONIA rate, compounded daily. The swap and the debt securities were acquired on the same day at prevailing market rates and designated in a cash flow hedge relationship for changes in 1-month SONIA, i.e., excluding credit risk from the debt securities.

As the hedged item and the hedging swap reference different indices, there is likely to be a difference between the hypothetical derivative and the actual hedging swap.

The hypothetical derivative representing the hedged risk in the issued debt might be determined as follows:

A 5-year interest rate swap with £200m notional, receiving 1-month SONIA, and paying a 2.02% fixed coupon monthly. The fixed coupon of 2.02% is calculated such that the hypothetical derivative has a zero fair value on the date of designation. The 2bp difference with the variable leg of the actual hedging swap reflects the difference between overnight SONIA compounding daily and 1-month SONIA (see section 7.4.5 below for a discussion on the selection of an appropriate discounting curve for calculation of fair value changes in the hypothetical derivative).

The fact that the actual hedging derivative is referenced to overnight SONIA and cash flows occur quarterly has no impact on the determination of the hypothetical derivative. The hypothetical derivative can only be based on features that arise in the hedged item, which attracts a monthly coupon. The difference between the hypothetical derivative and the hedging derivative is likely to lead to ineffectiveness (see section 7.4.1 above).

Illustration 7-13: Impact on ineffectiveness of changes in credit risk in the hedged item when the hedged risk is a benchmark rate component

Entity A has issued floating rate debt, paying a benchmark floating rate plus a credit spread of 1%. Entity A also transacts a pay fixed, receive benchmark interest rate swap in order to eliminate variability in cash flows from changes in the benchmark rate. The entity designates this swap as a hedge of the benchmark rate component of the issued debt and excludes credit risk on the debt from the hedge relationship. Accordingly, if subsequently Entity A's credit rating changes such that the current credit spread is now 0.95%, this will have no impact on the change in value of the hedged item for the purposes of measuring ineffectiveness, as credit risk in the hedged item has been excluded from the hedge relationship. Conversely, if there is a change in the credit risk with respect to the interest rate swap (either that of the counterparty or the entity itself), resulting in a change in the fair value of the interest rate swap, this would affect the measurement of hedge ineffectiveness. The credit risk associated with the interest rate swap includes both counterparty and own credit risk (see section 7.4.9 below).

When considering the credit risk of the hedged item, any changes must not be of a magnitude that it dominates the value changes in the hedged item such that the hedge effectiveness requirements are no longer met (see section 6.4.2.B above). That is unlikely to be the case for a change in credit spread from 1% to 0.95%.

One other example of when the features of the hedging instrument and the hedged item are likely to differ is when an entity hedges a debt instrument denominated in a foreign currency in a cash flow hedge with a cross-currency swap (irrespective of whether it is fixed-rate or variable-rate debt). IFRS 9 is explicit that when using a hypothetical derivative to calculate ineffectiveness, the hypothetical derivative cannot simply include an imputed charge for exchanging different currencies (i.e., the foreign currency basis spread) even though actual derivatives (for example, cross-currency interest rate swaps) under which different currencies are exchanged might include such a charge. [IFRS 9.B6.5.5]. Although cross-currency interest rate swaps are used to highlight the fact that foreign currency basis spreads must not be replicated in hypothetical derivatives, this issue is also likely to arise in other foreign currency contracts settled in the future. To address this, IFRS 9 includes the ability to account for the foreign currency basis spread as a cost of hedging (see section 7.5 below).

In many cases where the critical terms of the hedged item are closely matched by a hedging instrument which had a zero fair value on designation, the hypothetical derivative is likely to have similar terms to the actual hedging derivative - subject to the known differences mentioned above (e.g., foreign currency basis spreads and credit risk).

When hedging a one sided risk (i.e., to designate only changes in the cash flows or fair value of a hedged item above or below a specified price or other variable (see section 2.1 above)) additional considerations apply in determining an appropriate hypothetical derivative. Although the hypothetical derivative must be based on the features that occur in the hedged item, the hypothetical derivative must also reflect that one sided nature of the hedge relationship. [IFRS 9.B6.5.5]. This is usually achieved by the hypothetical derivative taking the form of the intrinsic value of a hypothetical option contract, matching the features of the hedged item where possible, but introducing a strike price above or below which the one sided risk arises. However, the time value associated with the hypothetical option contract is excluded from the hedge relationship as it is not a component of the hedged item (see section 7.4.11 below).

For hedges of risks other than one sided risks, the hypothetical derivative is required to have a zero fair value on designation. In the case of hypothetical derivatives for one sided risks, the intrinsic value of the hypothetical option must be zero (see section 3.6.4 above for discussion on acceptable ways to calculate the intrinsic value).

Illustration 7-14 below provides some examples as to how to identify an appropriate hypothetical derivative in the hedge of a one sided risk.

Illustration 7-14: Identifying an appropriate hypothetical derivative in the case of a one sided risk.

Company AA wishes to protect itself against a reduction in the price of Commodity X. It has highly probably forecast sales of 100 tonnes in 6 months time. The current price of 100 tonnes of Commodity X is CU11. Company AA purchases a floor with an underlying of 100 tonnes of Commodity X, for net settlement in 6 months time. Company AA designates the floor as a hedging instrument in a cash flow hedge of a one sided risk of Commodity X.

Set out below are three different scenarios each with a different strike price transacted in the actual hedging instrument.

Scenario 1

Company AA chooses to protect itself against a fall in the price of Commodity X below CU8, and so transacts an out of the money floor with a strike price of CU8, at premium of CU0.5. The floor has zero intrinsic value, the premium reflects time value.

The one sided risk is below CU8 so an appropriate hypothetical derivative would have a strike price of CU8, other terms of the hypothetical derivative must be based on the forecast sales in terms of timing and pricing features.

Scenario 2

Company AA chooses to protect itself against any fall in the price of Commodity X (i.e., below the current price of CU11), and so transacts an at the money floor with a strike price of CU11, at a premium of CU1. The floor has zero intrinsic value, the premium reflects time value.

The one sided risk is below CU11 so an appropriate hypothetical derivative would have a strike price of CU11, other terms of the hypothetical derivative must be based on the forecast sales in terms of timing and pricing features.

Scenario 3

Company AA transacts an in the money floor with a strike price of CU13, paying a premium of CU2.75, made up of intrinsic value of CU2 and time value of CU0.75.

If the floor was designated as the hedging instrument in a cash flow hedge of a one sided risk of Commodity X, the appropriate hypothetical derivative would have a strike price of CU11, i.e., the current market price for Commodity X and the level at which the intrinsic value reaches zero. The fact that the actual derivative is already in the money (i.e., has a positive intrinsic value) is not relevant for the hedged risk. The CU2 of intrinsic value represents changes in the price of Commodity X in the period prior to the hedge designation and so is not relevant for the hedge relationship. This would also be the case if Company AA had identified an existing in the money floor.

In all three scenarios, the time value associated with the hypothetical derivative is excluded from the hedge relationship as it is not a component of the hedged item (see section 7.4.11 below).

The issues in Illustration 7-14 above are also applicable in the determination of the aligned derivative when hedging a one sided risk and applying the cost of hedging (see section 7.5.1.A below).

The hypothetical derivative is first determined at inception of the hedge relationship based on the critical terms of the hedged item and prevailing market rates at that time. However, should any of the critical terms of the hedged item change subsequently, e.g., timing, volume or pricing inputs, then the hypothetical derivative will need to be updated to reflect those changes.

Although the terms of the hypothetical derivative are updated to reflect current expectations of the hedged item, it is still constructed based on market rates at inception of the hedge relationship. This is to ensure the cumulative change in fair value of the hedged item since inception of the hedge relationship is captured for measurement and assessment of effectiveness. [IFRS 9.6.4.1(c), IFRS 9.6.5.11(a)]. Illustration 7-15 below provides an example of a hypothetical derivative being updated due to changes in the hedged item.

Illustration 7-15: Change in expectations with respect to the hedged item

Entity Z, with USD functional currency, as at 1/1/20X2 expects to purchase 10 industrial ovens from a UK supplier. The price of the ovens will be determined in GBP and will be agreed on 30/6/20X2 when the purchase is expected to be confirmed, for delivery and settlement 2 months later. Z considers the purchase of the 10 ovens on 31/8/20X2 to be highly probable.

On 1/1/20X2, the price for each oven is GBP5,000, and historically the GBP price has been very stable. The USD/GBP forward rate on 1/1/20X2 for delivery on 31/8/20X2 is 0.8.

Z wishes to reduce its exposure to changes in cash flow (the purchase price) due to foreign exchange risk and so enters into a foreign currency forward contract to buy GBP50,000 and sell USD62,500 for settlement on 31/8/20X2.

It is assumed that the hedge qualifying criteria are all met (see section 6.1 above), and the foreign currency forward contract is designated in a cash flow hedge of the USD/GBP forward exchange risk in the highly probable purchase of 10 ovens on 31/8/20X2.

As the critical terms of the hedged item and the hedging foreign currency forward contract match, and the forward contract was transacted with a zero fair value, the hypothetical derivative representing the hedged item will have the same terms as the actual hedging foreign currency forward contract. This will not always be the case as demonstrated in Illustration 7-12 above.

The following month it becomes clear that only 8 ovens are required by Entity Z. In addition, the supplier is facing delays in its production line and so will not be able to deliver the ovens until 30/10/20X2.

Given the changes in volume and timing of the hedged item, the hypothetical derivative must be updated accordingly. The hypothetical derivative must be updated to take the form of a foreign exchange forward contract as follows: to buy GBP40,000 and sell USD51,282 for settlement on 30/10/20X2.

The notional of the hypothetical derivative has been reduced to reflect the purchase of 8 rather than 10 ovens. The USD/GBP forward rate of 0.78 applied to the forward contract still reflects market rates on 1/1/20X2 but for the new delivery date of 30/10/20X2.

It can be seen that given the changes in expectations of the hedged item, the hypothetical derivative no longer matches the hedging derivative and so some ineffectiveness is likely to arise. Although prospectively it is likely that Entity Z would undertake a partial dedesignation of the hedging instrument to reflect the GBP10,000 of hedged items that no longer exists (see section 8.3 below).

Illustration 7-16 (see section 7.4.6 below) contains a comprehensive example of the accounting entries for a cash flow hedge of interest rate risk in a forecast debt issuance using a hypothetical derivative for the calculation of ineffectiveness.

7.4.5 Discount rates for calculating the change in value of the hedged item

The standard is clear that entities must consider the time value of money when measuring hedge ineffectiveness. This means that an entity must determine the value of the hedged item on a present value basis (thereby including the effect of the time value of money) (see section 7.4.2 above). [IFRS 9.B6.5.4]. Although capturing the effect of the time value of money is a key aspect of the application of hedge accounting, little guidance is provided on how to calculate the time value in the hedged item. By contrast, guidance is given on how to calculate the fair value changes for hedging instruments in various places: in IFRS 13 for those held at fair value through profit or loss (see Chapter 15), and in IAS 21 for non-derivative hedging instruments of foreign currency risk (see section 3.3.1 above).

For example, a key consideration for market participants in calculating the fair value of derivatives is the selection of an appropriate discount rate. Although an interest rate swaps (IRS) might be referenced to one benchmark rate (e.g., 1 month SONIA) the appropriate discount rates for calculating fair value in line with IFRS 13 guidance, might be derived from a different benchmark rate (e.g., OIS for cash collateralised trades) if that is how market participants would calculate the fair value. Overnight index swaps (OIS) are interest rate swaps where the floating leg is linked to a benchmark interest rate for overnight lending. Market participants typically use OIS rates as a discount curve for cash collateralised IRS as they reflect the credit risk of such an instrument.

The way in which the time value of a hedged item is captured can have a significant impact on the measurement of ineffectiveness. This is illustrated in the following two examples.

Consider firstly the example of a fair value hedge of a fixed rate bond for changes in an eligible benchmark interest rate risk component (see section 2.2.3.A above). It is clear that in order to capture the change in value of the hedged fixed cash flows attributable to changes in the benchmark interest rate, the discounting curve would have to be based on the designated benchmark interest rate. For a fair value hedge of a specified interest rate, to choose any other discounting curve would reflect a risk other than the designated hedged risk. For such hedges, in order to reflect the hedged risk, that choice of hedged risk predetermines the discounting rate to be applied to the hedged item. Hence for a fair value hedge, unless the benchmark rate designated as the hedged risk is the same as the discounting curve applied to the hedging instrument, ineffectiveness will arise. This is the case even if the hedged fixed cash flows match exactly the fixed cash flows of the hedging instrument.

Now contrast this with the example of a benchmark interest rate (e.g., SONIA) floating rate debt, swapped into a fixed rate of interest using a receive-benchmark rate, pay-fixed interest rate swap, designated in a cash flow hedge for changes in the benchmark interest rate. For the purposes of calculating the change in the value of the hedged item due to the hedged risk, the entity could use a hypothetical derivative (see section 7.4.4 above). When measuring the fair value of the actual and hypothetical interest rate swaps, the entity would start by using the specified benchmark rate forward curve to forecast the future floating cash flows. However, potentially the discount rate applied to those future cash flows might not be the same as that used for forecasting. In the case of a collateralised swap (for which the relevant discount rate is likely to be an overnight rate (e.g., OIS), unless the value of the hypothetical derivative is also calculated using an OIS discounting curve, even though the future cash flows might be the same, changes in value of the hypothetical derivative and the fair value of the actual swap will not be same - resulting in ineffectiveness.

How we see it

For those hedge relationships where the discounting curve is not predetermined by the hedged risk (e.g., a cash flow hedge of a benchmark interest rate, in contrast to a fair value hedge of a benchmark interest rate for which the discount rate must reflect the hedged benchmark rate) the standard is not prescriptive, and practice has evolved such that there appears to be an element of choice as to which benchmark interest rate is used as the basis for discounting in the calculation of changes in value of the hypothetical derivative used to reflect the hedged risk in a cash flow hedge.

We believe this choice is limited to a benchmark interest rate. For example, it is not permissible to use a discount rate that would reflect the ongoing specific credit risk inherent in the hedging instrument, as this would reflect a feature of the hedging instrument rather than the hedged item (see section 7.4.4 above). Put differently, although it might be possible to choose the discounting benchmark rate for the hedged item to be that which is used for discounting purposes for the actual derivative, no such choice exists to reflect elements of the valuation of the actual derivative such as the credit valuation adjustment (CVA) in determining value changes in the hedged item (see Chapter 15). Hence changes in the specific credit risk inherent in the hedging instrument will still result in ineffectiveness. However, if the hedging derivative is collateralised, the use of an OIS curve for discounting the hedged item could result in very little ineffectiveness.

Similarly, the ability to choose a benchmark rate curve for discounting purposes when calculating a change in value of the hedged item, does not permit the inclusion of cross-currency spreads within such a curve - unless for a hedge of foreign currency risk and the cross-currency basis occurs in the hedged item (see section 7.4.4 above).

Any choice of discounting benchmark rate must be documented at the inception of the hedge relationship (see section 6.3 above).

As a result of the reforms mandated by the Financial Stability Board following the financial crisis, IBOR (including LIBOR) is being replaced by new 'official' benchmark rates, known as RFRs. IBOR Reform is ongoing, since whilst many IBORs have now transitioned to RFRs, some are temporarily continuing in synthetic form and some are still to transition. Such a change will necessarily affect both forecasting and discounting curves used to value financial instruments and could reduce the instances where there is a difference between discounting curves for the valuation of hedging derivatives and hedged items. However, this change in benchmark rates raises a number of accounting issues, including some related to hedge accounting. The IASB has published two amendments to IFRS 9 and other standards to address these issues: in September 2019, *Interest Rate Benchmark Reform, Amendments to IFRS 9, IAS 39 and IFRS 7*, and in August 2020 *Interest Rate Benchmark Reform Phase 2, Amendments to IFRS 9, IAS 39, IFRS 7, IFRS 4 Insurance Contracts and IFRS 16* (see the *Supplement: IBOR Reform*).

7.4.6 Comprehensive example of calculation of measuring ineffectiveness for a cash flow hedge of a forecast transaction in a debt instrument

Illustration 7-16 below contains a comprehensive example of the calculation of ineffectiveness and associated accounting entries for a cash flow hedge of a forecast debt issuance. A hypothetical derivative is used to measure the present value of the cumulative change in the hedged expected cash flows from inception of the hedge in order to measure effectiveness (see section 7.4.4 above). [IFRS 9.6.5.11(a)(ii)]. Using a hypothetical derivative is one possible way of calculating the change in the value of the hedged item and is probably the most frequently used for cash flow hedges. [IFRS 9.B6.5.5].

Illustration 7-16: Measuring ineffectiveness and associated accounting entries for a cash flow hedge of a forecast debt issuance

A forecast issuance of debt (or other interest-bearing liability or asset) for which the interest rate will be set when it is issued, creates a cash flow exposure to interest rate changes because the related interest payments will be based on the benchmark interest rate that exists when the forecast debt issuance occurs. In order to eliminate that cash flow variability with respect to market interest rates, it is common for entities to transact a forward starting interest rate swap in order to economically lock in the benchmark interest rate for the forecast debt issuance.

The forward starting interest rate swap could be designated as the hedging instrument in a cash flow hedge of benchmark interest rate risk from the forecast debt issuance. In order to be eligible for hedge accounting the forecast debt issuance must be highly probable of occurring (see section 2.6.1 above).

Fact Pattern

The date is 1/1/X0 and it is highly probable that Company X will issue a €100,000 one-year debt instrument in six months on 30/6/X0. The instrument will pay fixed interest quarterly with principal due at maturity on 30/6/X1.

X is exposed to interest rate increases and establishes a hedge of the interest cash flows of the forecast debt issue by entering into a forward starting interest rate swap. The swap has a term of one year and will start in six months time on 30/6/X0 to correspond with the terms of the forecast debt issue. X will pay a fixed rate and receive a variable rate on the interest rate swap. X designates the forward starting interest rate swap as the hedging instrument in a cash flow hedge of the benchmark interest rate risk component (e.g., 3M EURIBOR) within the forecast debt issue. When the forecast debt is issued, the interest rate swap is closed out and settled in cash.

The qualifying criteria for hedge accounting are all assumed to have been met (see section 6 above). X chooses to use the hypothetical derivative method in order to calculate ineffectiveness (see section 7.4.4 above).

As only the benchmark interest rate risk component has been designated, any other factors such as X's credit risk, are excluded from the hedge relationship, unless changes in such factors result in the debt being issued at a sub-benchmark rate (see section 2.4 above). For the purposes of this illustration, it is assumed that the debt is not issued at a sub-benchmark rate.

Set out below are the benchmark zero-coupon and forward rates required in order to establish the hypothetical derivative and to undertake the measurement of ineffectiveness and associated accounting entries.

Market data date	Annual benchmark interest rates	31/3/X0	30/6/X0	30/9/X0	31/12/X0	31/3/X1	30/6/X1
1/1/X0	Zero coupon rates	2.00%	2.25%	2.75%	3.50%	4.00%	4.25%
	Forward rates	2.00%	2.50%	3.76%	5.78%	6.02%	5.51%
31/3/X0	Zero coupon rates		3.00%	3.25%	3.75%	4.00%	4.25%
	Forward rates		3.00%	3.50%	4.76%	4.75%	5.26%
30/6/X0	Zero coupon rates			4.25%	5.00%	5.50%	5.75%
	Forward rates			4.25%	5.76%	6.51%	6.50%

Explanation of benchmark rates

The zero-coupon rates represent the interest rates that would be earned for principal amounts invested at inception in zero-coupon instruments without credit risk i.e., instruments where all interest is compounded and settled at maturity. For example, based on data as of 31/3/X0, a zero-coupon debt instrument issued on 31/3/X0 and having a maturity of 6 months (30/09/X0) will pay a zero-coupon interest rate of 3.25%.

The interest rates are expressed as annual rates, by convention. Please also note that the rates used in this example correspond to compounded rates (as opposed to nominal rates). As a consequence, in the above example, based on data as of 31/3/X0, the coupon paid for a principal amount invested at 31/3/X0 in a zero-coupon debt instrument with a maturity of 6 months will be equal to $(1+3.25\%)^{(6/12)}-1 = 1.61\%$. 1.61% is the *period-zero* coupon rate (as opposed to annual rate) corresponding to the *annual-zero* coupon rate of 3.25% for a period of 6 months. The de-compounding to derive a 6 month coupon rate was achieved by the $^{(6/12)}$ element of the calculation.

Zero coupon rates are used to determine appropriate discount rates. Using again the benchmark data provided above, on 31/3/X0 the appropriate discount rate for a cash flow occurring on 30/9/X0 (i.e., 6 months later) would be 1.61%, as calculated above. Hence a cash flow of €100 occurring on 30/9/X0 would have a present value on 31/03/X0 of $€100 / (1+1.61\%) = €98.4$.

The forward rates for each period are sometimes called forward rates beyond the first period. They represent the annualised market rate of interest that would accrue and be paid at the end of a single period assuming investment at the beginning of the forward-starting period. They are also expressed as annual rates in this example.

Forward rates can be derived from the zero coupon rates. For example, the 3 month forward rate starting on 31/3/X0 (i.e., in 3 months' time) is $((1+2.25\%)^{(6/12)}) / ((1+2.00\%)^{(3/12)})^{(12/3)}-1 = 2.50\%$, based on current market data (as at 1/1/X0). The formulae is based on the premise that it is financially equivalent to invest €100 at inception (1/1/X0) for a period of 6 months (applying the 6 month zero coupon rate) and to invest €100 at inception (1/1/X0) for a period of 3 months (zero coupon and forward rate are equal for this period) and reinvest principal plus interests for another period of 3 months (at the forward rate for this 3 month period).

Forward rates are used to determine expected future cash flows. For example, the forward rate used to determine the expected cash flows of a future 3-month floating rate bond would be as follows:

A 3 month floating rate bond is expected to be issued on 30/6/X0, the expectation on 1/1/X0 would be that interest payable on maturity at 30/9/X0 would be $€100,000 \times ((1+3.76\%)^{(3/12)}-1) = €926$. 3.76% is the 3 month forward rate of interest starting on 30/6/X0 (in 6 months time), but quoted on an annual basis, so there is a need to convert it into a discreet 3 month basis rate by de-compounding, which is achieved by the $^{(3/12)}$ element of the previous calculation.

Calculation of the fixed rate of a debt instrument, based on market rates

When a fixed interest rate debt instrument with payment of quarterly coupons is expected to be issued at a future date, its expected fixed rate can be calculated based on zero coupon rates. This fixed interest rate would be equal to the fixed interest of an interest rate swap (IRS) exchanging it against floating interest rates, where the floating interest rates would be based on the forward interest rates corresponding to each period - this fixed rate is commonly referred to as the "swap rate".

In practice, this implied or expected fixed rate is calculated by solving for the fixed rate of interest that is required to bring the fair value of the swap to zero, or the fair value of the fixed rate debt to par using the zero coupon rates for discounting purposes. This is an iterative approach, often referred to as bootstrapping, and is too complex to demonstrate here. For an interest rate swap or a fixed rate debt with interest settling every 3 months with a forward starting date on 30/6/X0, the implied fixed rate would be calculated so that the fair value of the swap was zero, and the fair value of the fixed rate debt was par at 30/6/X0, but based on current market data (as at 1/1/X0).

In this example, using the above current market data (1/1/X0), and applying bootstrapping, the quarterly settled implied annual fixed rate on a 1-year fixed rate debt expected to be issued on 30/6/X0 would be 5.155%. This is quoted as an annual nominal rate, with the rate attributable to each quarterly settlement being calculated as $5.155\% \times 3/12 = 1.289\%$. The fixed rate of an IRS with a forward starting date as of 30/06/X0, a maturity of 1 year and quarterly payments, would be the same.

The intention of Company X is to lock in the expected fixed rate of its future issuance at this implied fixed rate of 5.155% by settling the forward starting swap with this fixed interest rate.

Hypothetical derivative

The first step in measuring ineffectiveness using a hypothetical derivative is to determine its terms, i.e., establish a notional derivative that has terms that match the critical terms of the hedged exposure and a zero fair value at inception of the hedging relationship (see section 7.4.4 above). An interest rate swap with a notional of €100,000 starting in 6 months time with a maturity of 1 year paying a fixed rate (quarterly) based on market data at 1/1/X0, receiving a benchmark swap rate would be an appropriate hypothetical derivative in this case.

The hedge is designated on the same day that the swap is transacted and, in this fact pattern, as no other sources of ineffectiveness exist, the hypothetical derivative also attracts the same fixed rate as the hedging swap of 5.155%. This will not always be the case, as an entity cannot include features in the hypothetical derivative that only exist in the hedging instrument, but not in the hedged item (see section 7.4.4 above).

The fair value of the hypothetical derivative can then be used as a proxy to measure the change in the present value of the hedged item against which changes in value of the actual hedging instrument are compared in order to calculate ineffectiveness.

Terms of the hypothetical derivative at 1/1/X0

	1/1/X0	31/3/X0	30/6/X0	30/9/X0	31/12/X0	31/3/X1	30/6/X1
Interest cash flows on the hypothetical derivative:	€	€	€	€	€	€	€
Fixed interest at 5.155%				(1,289)	(1,289)	(1,289)	(1,289)
Forecast floating interest ⁽¹⁾				926	1,415	1,473	1,350
<i>Net interest cash flow</i>				(363)	126	184	61
Present value of net cash flows at 1/1/X0 ⁽²⁾				(355)	122	176	57
Total Present value at 1/1/X0	nil						

(1) Forecast floating interest is determined with respect to the forward rate for the quarterly period, in which case the annual rates need to be converted. For example, forecast floating rate coupon payable at 31/12/X0 = €100,000*((1+5.78%)^(3/12)-1) = €1,415.

(2) Present value of net cash flows is calculated by discounting back to 1/1/X0 at the zero coupon rate for the period. For example, the present value of the net interest cash flow expected at 31/03/X1 is calculated as follows: €184*1/((1+4.00%)^(15/12)) = €176.

(3) Only the interest cashflows from the hypothetical derivative are considered above for the purposes of calculating the present value. This is because the theoretical cash flows described as principal in the fixed and floating legs offset exactly, and do not contribute to the present value of the derivative.

For the purposes of this illustration, we have assumed that there are no sources of ineffectiveness, such that changes in the present value of the hypothetical derivative will match exactly fair value changes in the hedging swap. Therefore, we have not set out the cash flows and fair values of the hedging swap, as they are the same as that of the hypothetical derivative in this case.

Measuring hedge effectiveness and accounting at 1/1/X0

No accounting entries are required at 1/1/X0, the hedged item is still only a forecast transaction, and the hedging swap was transacted for zero consideration, equal to its fair value.

Measuring hedge effectiveness and accounting at 31/3/X0

	31/3/X0	30/6/X0	30/9/X0	31/12/X0	31/3/X1	30/6/X1
Interest cash flows on the hypothetical derivative:	€	€	€	€	€	€
Fixed interest at 5.155%			(1,289)	(1,289)	(1,289)	(1,289)
Forecast floating interest ⁽¹⁾			864	1,169	1,168	1,289
<i>Net interest cash flow</i>			(425)	(120)	(121)	0
Present value of net cash flows at 31/3/X0			(418)	(117)	(116)	0
Total Present value at 31/3/X0	(651)					

(1) Forecast floating interest is determined with respect to the forward rate for the quarterly period, in which case the annual rate needs to be converted. For example, forecast floating rate coupon payable at 30/6/X1 = €100,000*((1+5.26%)^(3/12)-1) = €1,289

(2) Present value of net cash flows is calculated by discounting back to 31/3/X0 at the zero coupon rate for the period. For example, the present value of the net interest cash flow expected at 31/03/X1 is calculated as follows: (€121)/(1+4.00%) = (€116).

The accounting entries at 31/3/X0 are as follows:

	€	€
Dr Cash flow hedge reserve	651	
Cr Derivative fair value		651

To record the change in the hedging swap fair value. As the cumulative change in fair value of the hedging swap exactly matches the cumulative change in present value of the hedged item (i.e., the hypothetical derivative), the full change in fair value of the hedging swap is taken to the cash flow hedge reserve within Other Comprehensive Income (OCI). (This will not always be true, in which case the 'lower of' assessment must be made to determine the effective portion to be taken to OCI (see section 7.2 above)).

No other accounting entries are required as no cash flows have yet arisen on the hedging swap or the forecast debt issuance.

Measuring hedge effectiveness and accounting at 30/6/X0

The forecast fixed rate debt is issued at a rate of 5.617%. This is based on the prevailing zero coupon rates (as provided in table of benchmark rates above) converted into the benchmark 1-year quarterly swap rate applying a bootstrapping methodology, (as mentioned above). Accordingly, the debt is issued at its par value of €100,000.²⁷

	30/6/X0	30/9/X0	31/12/X0	31/3/X1	30/6/X1
Interest cash flows on the hypothetical derivative:	€	€	€	€	€
Fixed interest at 5.155%		(1,289)	(1,289)	(1,289)	(1,289)
Forecast floating interest ⁽¹⁾		1,046	1,409	1,589	1,588
<i>Net interest cash flow</i>		(243)	120	300	299
Present value of net cash flows at 30/6/X0 ⁽²⁾		(240)	117	288	283
Total Present value at 30/6/X0	448				

(1) Forecast floating interest is determined with respect to the forward rate for the quarterly period based on 30/6/X0 market data. For example, forecast floating rate coupon payable at 31/12/X0 = $€100,000 * ((1 + 5.76\%)^{(3/12)} - 1) = €1,409$.

(2) Present values of net cash flows are calculated by discounting back to 30/6/X0 at the zero coupon rate for the period. For example, the present value of the net interest cash flow expected at 31/3/X1 is calculated as follows: $€300 * 1 / ((1 + 5.50\%)^{(9/12)}) = €288$.

As the fixed rate debt has now been issued and there is no more variability in cash flows due to the benchmark interest rate risk, Company X closes out the hedging swap for its fair value at 30/6/X0 of €448. This results in the discontinuation of the hedge relationship prospectively as the hedging instrument no longer exists (see section 8.3 below).

The accounting entries at 30/6/X0 are as follows:

	€	€
Dr Cash	100,000	
Cr Debt issuance		100,000

To record the cash proceeds raised from issuing at par €100,000 of 5.617% fixed rate debt paying a quarterly coupon.

	€	€
Dr Derivative fair value	1,099	
Cr Cash flow hedge reserve		1,099

To record the change in the hedging swap fair value, an increase of €1,099 in the period. As the cumulative change in fair value of the hedging swap of €448 (i.e., = (€651) + €1,099) exactly matches the cumulative change in present value of the hedged item (i.e., the hypothetical derivative), the full change in fair value of the hedging swap is taken to the cash flow hedge reserve within Other Comprehensive Income (OCI). (This will not always be true, in which case the 'lower of' assessment must be made to determine the effective portion to be taken to OCI (see section 7.2 above)).

Dr	Cash	448	
	Cr	Derivative fair value	448

To record the full settlement of the hedging swap.

A summary of the cumulative accounting entries at 30/6/X0 is shown below:

DR/(CR)	Cash	Hedging Swap	Cash flow hedge reserve	Debt issuance	Interest expense
	€	€	€	€	€
31/3/X0					
Change in fair value of hedging swap		(651)	651		
30/6/X0					
Debt issuance	100,000			(100,000)	
Change in fair value of hedging swap		1,099	(1,099)		
Settlement of hedging swap	448	(448)			
Total	100,448	-	(448)	(100,000)	

Accounting entries at 30/9/X0

Now that the fixed rate debt has been issued, there is no more variability in the cash flows with respect to interest rate risk and the hedge relationship has been discontinued prospectively. The debt issued is accounted for at amortised cost, with an effective yield of 5.617% (with a linear calculation). Further, as the swap has been closed out, no further fair value changes will occur. Consequently, benchmark market data is not required for the accounting entries in the remaining periods.

The accounting entries at 30/9/X0 are as follows:

		€	€
Dr	Interest expense	1,404	
	Cr	Cash	1,404

To record the cash payment on the quarterly coupon payment (5.617%) on the debt issuance.

		€	€
Dr	Cash flow hedge reserve	112	
	Cr	Interest expense	112

To record the reclassification of the effective portion of the hedging swap's fair value change out of the cash flow hedge reserve to interest expense over the same periods that the hedged cash flows impact profit or loss (see section 7.2 above). [IFRS 9.6.5.11(d)(ii)]. The reclassification has been calculated on a straight line basis over the four periods the debt is expected to impact profit or loss €112 = €448/4, although the standard does not specify a method.

The use of a revised effective interest rate would also be an acceptable method to reclassify the effective portion from the cash flow hedge reserve into profit or loss.

27 Present value at 30/6/X0 of the 5.617% 1 year fixed rated debt, with quarterly coupons of 1.404% (i.e., annualised swap rate of 5.617%/4 = a quarterly coupon rate of 1.404%) is: €100,000 = €100,000 * ((1.404%/(1+4.25%)^(3/12)) + (1.404%/(1+5.0%)^(6/12)) + (1.404%/(1+5.5%)^(9/12)) + ((1+1.404%)/(1+5.75%)^(12/12)))

For cash flows hedges of floating rate debt for which the hedging derivative remains in place once the debt is issued, the effective portion of the hedging swap will continue to be remeasured. In that case the reclassification of that effective portion can in some cases be achieved by recognising changes in the clean fair value of the hedging derivative in the cash flow hedge reserve and the net interest payable/receivable recognised in interest expense (see section 7.2.2 above).

The accounting entries for 31/12/X0 and 31/3/X1 are exactly the same as those for 30/9/X0 and so are not repeated again here.

Accounting entries at 30/6/X1

		€	€
Dr	Interest expense	1,404	
	Cr Cash		1,404

To record the cash payment on the quarterly coupon payment (5.617%) on the debt issuance.

		€	€
Dr	Cash flow hedge reserve	112	
	Cr Interest expense		112

To record the reclassification of the effective portion of the hedging swap's fair value change out of the cash flow hedge reserve to interest expense over the same periods that the hedged cash flows impact profit or loss (see section 7.2 above). [IFRS 9.6.5.11(d)(ii)].

		€	€
Dr	Debt issuance	100,000	
	Cr Cash		100,000

To record the repayment of the €100,000 fixed rate debt.

A summary of the cumulative accounting entries at 30/6/X1 is shown below:

DR/(CR)	Cash	Hedging Swap	Cash flow hedge reserve	Debt issuance	Interest expense
	€	€	€	€	€
<i>B/F balances from 30/6/X0</i>	100,448	-	(448)	(100,000)	
<i>30/9/X0</i>					
Interest coupon paid	(1,404)				1,404
<i>Reclassification from OCI</i>			112		(112)
<i>31/12/X0</i>					
Interest coupon paid	(1,404)				1,404
<i>Reclassification from OCI</i>			112		(112)
<i>31/3/X1</i>					
Interest coupon paid	(1,404)				1,404
<i>Reclassification from OCI</i>			112		(112)
<i>30/6/X1</i>					
Interest coupon paid	(1,404)				1,404
<i>Reclassification from OCI</i>			112		(112)
<i>Debt issuance repaid</i>	(100,000)			100,000	
Total	5,168	-	-	-	(5,168)

It can be seen that after the effects of cash flow hedge accounting, total interest expense paid was €5,168, rather than the actual €5,617 interest expense paid on the debt issuance at 5.617%, reflecting the lower interest rate locked in on 1/1/X0. It is also important to note that there is nothing left in the cash flow hedge reserve when the hedged cash flows have all occurred and will no longer impact profit or loss. One other thing to note is that the 5.168% yield achieved following hedge accounting is not the same as the fixed leg of the hedging swap of 5.155%. The difference arises mainly from the effect of discounting on the future cash flows of the hedging swap on 30/6/X0 which is never unwound as the swap is closed out on that date once the debt is issued.²⁸

7.4.7 Worked examples of spot rate and forward rate designations, plus the application of the costs of hedging accounting

It was explained in section 3.6.5 above that the spot and forward elements of a forward contract can be treated separately for the purposes of hedge designation. Further, that if only the spot element is selected, a further choice is available as to whether the excluded elements are accounted for as costs of hedging or not (see section 7.5 below). Illustration 7-17 below contrasts how the assessment of effectiveness and calculation of ineffectiveness must be applied for a hedge relationship depending on the choices made on designation.

Illustration 7-17: Cash flow hedge of highly probable forecast purchase of inventory in a foreign currency

Company A has the Local Currency (LC) as its functional and presentation currency.

On 1 January 20X3, A enters into a forward exchange contract to receive Foreign Currency (FC) 100,000 and deliver LC109,600 on 30 June 20X3 at an initial cost and fair value of zero. On inception, it designates the forward exchange contract as a hedging instrument in a cash flow hedge of a highly probable forecast purchase of a certain quantity of paper for FC100,000 on 30 June 20X3. It is assumed that all hedge accounting conditions in IFRS 9 are met.

The relevant foreign currency rates and associated fair values for the forward exchange contract are provided in the following table:

Date	Spot rate	Forward rate to 30 June 20X3	Fair value of forward contract
1 January 20X3	1.072	1.096	-
31 March 20X3	1.074	1.076	(1,980)
30 June 20X3	1.075	-	(2,100)

For simplification purposes foreign currency basis risk is assumed to be zero. The applicable yield curve in the local currency is flat at 4% per annum throughout the period. The fair value of the forward exchange contract is negative LC1,980 on 31 March 20X3 ($\{[1.076 \times 100,000] - 109,600\} \div 1.04^{(3/12)}$), and negative LC2,100 on 30 June 20X3 ($1.075 \times 100,000 - 109,600$).

Case 1: Changes in the forward rate of the forward exchange contract are designated in the hedge relationship

Ignoring ineffectiveness that might arise from other elements that have an impact on the fair value of the hedging instrument (such as foreign currency basis spreads (see section 7.4.8 below)), the hedge is expected to be fully effective because the critical terms of the forward exchange contract and the purchase contract are otherwise the same. The assessments of hedge effectiveness are based on the forward rate.

The accounting entries are as follows.

	1 January 20X3	LC	LC
Dr	Forward exchange contract	-	
Cr	Cash		-
<i>To record the forward exchange contract at its initial fair value, i.e., zero.</i>			
	31 March 20X3	LC	LC
Dr	OCI - cash flow hedge reserve	1,980	
Cr	Forward exchange contract - liability		1,980

²⁸ If Company X had issued a floating rate debt (instead of a fixed rate debt) and had not early settled the IRS as of 30/6/X0 (but kept it until its 30/6/X1 maturity), then the total amount of interests paid on the debt plus the net interests paid/received on the IRS would have been exactly equal to €5,155 (corresponding exactly to the 'hedged' fixed rate).

To recognise the change in the fair value of the forward exchange contract between 1 January 20X3 and 31 March 20X3, i.e., $1,980 - 0 = \text{LC}1,980$, in other comprehensive income (OCI) within the cashflow hedge reserve. The hedge is considered fully effective because the loss on the forward exchange contract, LC1,980, exactly offsets the change in cash flows associated with the purchase contract based on the forward price $\{([1.076 \times 100,000] - 109,600) \div 1.04^{(3/12)}\} - \{([1.096 \times 100,000] - 109,600) \div 1.04^{(6/12)}\} = -\text{LC}1,980$. The negative figure denotes a reduction in the net present value of cash outflows and, therefore, effectively represents a 'gain' to offset the loss on the forward exchange contract in OCI.

The second element of the above equation equals zero (i.e., $(1.096 \times 100,000 - 109,600) = 0$). This reflects the fact that the forward exchange contract is on market and accordingly has a zero present value on designation. Where this is the case, the calculation could be simplified as follows:

$\{([1.076 \times 100,000] - 109,600) \div 1.04^{(3/12)}\} = -\text{LC}1,980$.

30 June 20X3		LC	LC
Dr	OCI - cash flow hedge reserve	120	
Cr	Forward exchange contract - liability		120

To recognise the change in the fair value of the forward exchange contract between 31 March 20X3 and 30 June 20X3, i.e., $2,100 - 1,980 = \text{LC}120$, in OCI within the cash flow hedge reserve. The hedge is considered fully effective because the loss on the forward exchange contract, LC120, exactly offsets the change in cash flows associated with the purchase contract based on the forward price $\{([1.075 \times 100,000] - 109,600)\} - \{([1.076 \times 100,000] - 109,600) \div 1.04^{(3/12)}\} = -\text{LC}120$. The negative figure denotes a reduction in the net present value of cash outflows and, therefore, effectively represents a 'gain' to offset the loss on the forward exchange contract in OCI.

	LC	LC
Dr	Paper (purchase price)	107,500
Dr	Paper (recycled hedging loss)	2,100
Cr	OCI - cash flow hedge reserve	2,100
Cr	Payable	107,500

To record the purchase of the paper at the spot rate ($1.075 \times 100,000 = \text{LC}107,500$) and remove the cumulative loss on the forward recognised in OCI from equity, LC2,100, and include it in the initial measurement of the purchased paper (see section 7.2.2 above). Accordingly, the initial measurement of the purchased paper is LC109,600 consisting of a purchase consideration of LC107,500 and a hedging loss of LC2,100. This represents the 1.096 forward foreign currency rate achieved through the forward exchange contract. [IFRS 9.6.5.11(d)(i)].

The payable is recorded as a foreign currency monetary item of FC100,000, equivalent to LC107,500 ($100,000 \times 1.075$) on initial recognition.

	LC	LC
Dr	Forward exchange contract - liability	2,100
Cr	Cash	2,100

To record the net settlement of the forward exchange contract.

Case 2: Changes in the spot element of the forward exchange contract only are designated in the hedge relationship (costs of hedging guidance is not applied)

Ignoring ineffectiveness that might arise from other elements that have an impact on the fair value of the hedging instrument, (such as foreign currency basis spreads (see section 7.4.8 below)), the hedge is expected to be fully effective because the critical terms of the forward exchange contract and the purchase contract are the same and the change in the forward element of the forward exchange contract is excluded from the assessment of effectiveness.

The assessment of hedge effectiveness is based on changes in the present value of the spot element. For this purpose, the spot element is calculated as the foreign currency cashflow translated at the prevailing spot rate on assessment date, less the deemed local currency cashflow as per spot rates on designation date. The present value is then calculated by discounting the spot element from the date the hedged item is expected to occur back to the assessment date, using discount factors derived from the applicable local currency yield curve. Changes in value of the excluded forward element are outside the hedge relationship and will be taken to profit or loss.

1 January 20X3		LC	LC
Dr	Forward exchange contract	-	
Cr	Cash		-

To record the forward exchange contract at its initial fair value, i.e., zero.

	31 March 20X3	LC	LC
Dr	Profit or loss (forward element)	2,178	
Cr	Forward exchange contract - liability		1,980
Cr	OCI - cash flow hedge reserve (spot element)		198

To recognise the change in the fair value of the forward exchange contract between 1 January 20X3 and 31 March 20X3, i.e., $1,980 - 0 = \text{LC}1,980$. The change in the present value of the spot element of the forward exchange contract is a gain of $\text{LC}198 = \{([1.074 \times 100,000] - 107,200) \div 1.04^{(3/12)}\} - \{([1.072 \times 100,000] - 107,200) \div 1.04^{(6/12)}\}$, which is recognised in OCI within the cash flow hedge reserve. As noted above, the second element of the above equation equals zero (i.e., $(1.072 \times 100,000) - 107,200 = 0$). This reflects the fact that the spot element of the forward exchange contract is on market and accordingly has a zero present value on designation. Where this is the case, the calculation could be simplified as follows:

$$\{([1.074 \times 100,000] - 107,200) \div 1.04^{(3/12)}\} = \text{LC}198.$$

The present value of the spot element of the forward exchange contract is calculated, as there is a need to consider the time value of money for effectiveness purposes (see section 7.4.2 above).

The hedge is considered fully effective because the gain in the present value of the spot element of the forward exchange contract, $\text{LC}198$, exactly offsets the change in the purchase price at spot rates $\{([1.074 \times 100,000] - 107,200) \div 1.04^{(3/12)}\} - \{([1.072 \times 100,000] - 107,200) \div 1.04^{(6/12)}\} = \text{LC}198$. The positive figure denotes an increase in the net present value of cash outflows and, therefore, effectively represents a 'loss' to offset the spot element gain on the forward exchange contract in OCI.

However, as the forward element is not part of the hedged risk, the change in value of the forward element of the forward exchange contract, a loss of $\text{LC}2,178 = 1,980 + 198$, is recognised in profit or loss. The value of the forward element is calculated as the difference between the full fair value change in the forward exchange contract and the change in the present value of the spot element.

	30 June 20X3	LC	LC
Dr	Profit or loss (forward element)	222	
Cr	Forward - liability		120
Cr	OCI - cash flow hedge reserve (spot element)		102

To recognise the change in the fair value of the forward exchange contract between 31 March 20X3 and 30 June 20X3, i.e., $2,100 - 1,980 = \text{LC}120$. The change in the present value of the spot element of the forward exchange contract is a gain of $\text{LC}102 = \{([1.075 \times 100,000] - 107,200)\} - \{([1.074 \times 100,000] - 107,200) \div 1.04^{(3/12)}\}$, which is recognised in OCI within the cash flow hedge reserve.

The hedge is considered fully effective because the gain in the present value of the spot element of the forward exchange contract, $\text{LC}120$, exactly offsets the change in the purchase price at spot rates $\{([1.075 \times 100,000] - 107,200)\} - \{([1.074 \times 100,000] - 107,200) \div 1.04^{(3/12)}\} = \text{LC}102$. The positive figure denotes an increase in the net present value of cash outflows and, therefore, effectively represents a 'loss' to offset the spot element gain on the forward exchange contract in OCI.

However, as the forward element is not part of the hedged risk, the change in value of the forward element of the forward exchange contract, a loss of $\text{LC}222 = -120 - 102$, is recognised in profit or loss.

		LC	LC
Dr	Paper (purchase price)	107,500	
Dr	OCI - cash flow hedge reserve (spot element)	300	
Cr	Paper (recycled hedging gain)		300
Cr	Payable		107,500

To recognise the purchase of the paper at the spot rate ($1.075 \times 100,000 = \text{LC}107,500$) and remove the cumulative gain on the spot element of the forward exchange contract that has been recognised in OCI within the cash flow hedge reserve ($198 + 102 = \text{LC}300$) and include it in the initial measurement of the purchased paper (see section 7.2.2 above). [IFRS 9.6.5.11(d)(i)].

Accordingly, the initial measurement of the purchased paper is $\text{LC}107,200$, consisting of the purchase consideration of $\text{LC}107,500$ and a hedging gain of $\text{LC}300$. This represents the 1.072 spot foreign currency rate achieved through the forward exchange contract. The change in value of the forward element, a loss of $\text{LC}2,400$, remains in profit or loss.

	LC	LC

Cr Cash		2,100

To record the net settlement of the forward exchange contract.

Case 3: Changes in the spot element of the forward exchange contract only are designated in the hedge relationship, while the forward element is treated as a cost of hedging

Ignoring ineffectiveness that might arise from other elements that have an impact on the fair value of the hedging instrument, (such as foreign currency basis spreads (see section 7.4.8 below)), the hedge is expected to be fully effective because the critical terms of the forward exchange contract and the purchase contract are the same and the change in the forward element of the forward exchange contract is excluded from the assessment of effectiveness.

The assessment of hedge effectiveness is based on changes in the present value of the spot element. For this purpose, the spot element is calculated as the foreign currency cashflow translated at the prevailing spot rate on assessment date, less the deemed local currency cashflow as per spot rates on designation date. The present value is then calculated by discounting the spot element from the date the hedged item is expected to occur back to the assessment date, using discount factors derived from the applicable local currency yield curve. Changes in value of the excluded forward element are outside the hedge relationship and are treated as a cost of hedging a transaction related hedged item. [IFRS 9.6.5.15, IFRS 9.6.5.16].

	LC	LC
1 January 20X3		
Dr Forward exchange contract	-	
Cr Cash		-

To record the forward exchange contract at its initial fair value, i.e., zero.

	LC	LC
31 March 20X3		
Dr OCI - separate component of equity (forward element)	2,178	
Cr Forward exchange contract - liability		1,980
Cr OCI - cash flow hedge reserve (spot element)		198

To recognise the change in the fair value of the forward exchange contract between 1 January 20X3 and 31 March 20X3, i.e., $1,980 - 0 = \text{LC}1,980$. The change in the present value of the spot element of the forward exchange contract is a gain of $\text{LC}198 = \{([1.074 \times 100,000] - 107,200) \div 1.04^{(3/12)}\} - \{([1.072 \times 100,000] - 107,200) \div 1.04^{(6/12)}\}$, which is recognised in OCI within the cash flow hedge reserve. As noted above, the second element of the above equation equals zero (i.e., $(1.072 \times 100,000) - 107,200 = 0$). This reflects the fact that the spot element of the forward exchange contract is on market and accordingly has a zero present value on designation. Where this is the case, the calculation could be simplified as follows: $\{([1.074 \times 100,000] - 107,200) \div 1.04^{(3/12)}\} = \text{LC}198$.

The present value of the spot element of the forward exchange contract is calculated as there is a need to consider the time value of money for effectiveness purposes (see section 7.4.2 above).

The hedge is considered fully effective because the gain on the spot element of the forward exchange contract, $\text{LC}198$, exactly offsets the change in the purchase price at spot rates $\{([1.074 \times 100,000] - 107,200) \div 1.04^{(3/12)}\} - \{([1.072 \times 100,000] - 107,200) \div 1.04^{(6/12)}\} = \text{LC}198$. The positive figure denotes an increase in the net present value of cash outflows and, therefore, effectively represents a 'loss' to offset the gain on the forward exchange contract in OCI.

Applying the costs of hedging guidance to the forward element of the forward exchange contract (see section 7.5 below), the change in the forward element (the change in value not designated as part of the hedged risk), a loss of $\text{LC}2,178 = 1,980 + 198$, is recognised in a separate component of equity.

In this example, as the critical terms of the hedged item and hedging instrument match, the value of the forward element is calculated as the difference between the full fair value change in the forward exchange contract and the change in the present value of the spot element.

Only the change in value of the forward element that relates to the hedged item can be accumulated in a separate component of equity, therefore where differences exist between the hedged item and hedging instrument, there is a need to calculate the appropriate forward element using an aligned instrument based on the terms of the hedged item (see section 7.5.1.A below).

	LC	LC
30 June 20X3		
Dr OCI - separate component of equity (forward element)	222	
Cr Forward exchange contract - liability		120
Cr OCI - cash flow hedge reserve (spot element)		102

To recognise the change in the fair value of the forward exchange contract between 31 March 20X3 and 30 June 20X3, i.e., $2,100 - 1,980 = \text{LC}120$. The change in the present value of the spot element of the forward exchange contract is a gain of $\text{LC}102 = \{([1.075 \times 100,000] - 107,200)\} - \{([1.074 \times 100,000] - 107,200) \div 1.04^{(3/12)}\}$, which is recognised in OCI within the cash flow hedge reserve.

The hedge is considered fully effective because the gain in the spot element of the forward exchange contract, $\text{LC}120$, exactly offsets the change in the purchase price at spot rates $\{([1.075 \times 100,000] - 107,200)\} - \{([1.074 \times 100,000] - 107,200) \div 1.04^{(6/12)}\} = \text{LC}102$. The positive figure denotes an increase in the net present value of cash outflows and, therefore, effectively represents a 'loss' to offset the spot element gain on the forward exchange contract in OCI.

Applying the costs of hedging guidance to the forward element of the forward exchange contract (see section 7.5 below); the change in value of the forward element of the forward exchange contract (the change in value not designated as part of the hedged risk) is a loss of $\text{LC}222 = -120 - 102$, is recognised in a separate component of equity.

	LC	LC
Dr Paper (purchase price)	107,500	
Dr Paper (cost of hedging)	2,400	
Dr OCI - cash flow hedge reserve (spot element)	300	
Cr Paper (recycled hedging gain)		300
Cr OCI - separate component of equity (forward element)		2,400
Cr Payable		107,500

To recognise the purchase of the paper at the spot rate ($1.075 \times 100,000 = \text{LC}107,500$), remove the cumulative gain on the spot element of the forward exchange contract that has been recognised in OCI within the cash flow hedge reserve ($198 + 102 = \text{LC}300$) and the cost of hedging recognised in a separate component of equity ($2,178 + 222 = \text{LC}2,400$) and include them in the initial measurement of the purchased paper. The inclusion of the cost of hedging as part of the initial measurement of the purchased paper is consistent with the required treatment of such a transaction related hedged item. For a time-period related hedged item, such as an interest rate swap hedging interest rate risk in a debt security, the timing and presentation of the removal of amounts from the separate component of equity is different (see Illustration 7-18 and section 7.5.1 below). [IFRS 9.6.5.11(d)(i), IFRS 9.6.5.15, IFRS 9.6.5.16].

Accordingly, the initial measurement of the purchased paper is $\text{LC}109,600$, consisting of the purchase consideration of $\text{LC}107,500$, a hedging gain of $\text{LC}300$ and the cost of hedging of $\text{LC}2,400$. This is equivalent to the 1.096 forward foreign currency rate achieved through the forward exchange contract.

	LC	LC
Dr Forward exchange contract- liability	2,100	
Cr Cash		2,100

To record the net settlement of the forward exchange contract.

In all these examples we have ignored foreign currency basis risk in the forward rate (see section 7.4.8 below). However, if we were to consider it, additional volatility in profit or loss may arise in Case 1, as foreign currency basis is not part of the hedged risk therefore any fair value changes in the hedging instrument due to foreign currency basis are not replicated in the hedged item. In Cases 2 and 3 above, the calculation method for the forward element would by default also include any foreign currency basis, i.e., the 'residual' after the spot element is deducted from the full fair value changes. However, in Case 3, foreign currency basis could be considered part of cost of hedging, similar to the forward element. [IFRS 9.6.5.16].

The example illustrates that the time value of money is relevant for the assessment of effectiveness even when the spot element is designated in a hedge relationship (see section 7.4.2 above). However, in many circumstances the effect of discounting the revaluation of the spot element might not be material.

In the above example the strategy was to protect against changes in foreign currency rates until the date the forecast purchase is expected to occur, perhaps on the assumption that the resulting foreign currency payable will be settled on the same day. An alternative, perhaps more common, hedging strategy is to protect against changes in foreign currency rates until the date the payable is expected to be settled. It is usually possible to achieve hedge accounting for such a strategy. In fact, there are a number of ways in which hedge accounting could be achieved.

One such approach would be to designate the hedging instrument in a cash flow hedge to protect against changes in foreign currency rates in cash flows associated with a highly probable forecast purchase.

Although the hedge relationship will end when the purchase is recognised, the hypothetical (and aligned) instrument (see section 7.4.4 above and section 7.5 below) could reflect the timing of the expected settlement of the associated trade payable, and so will provide good offset to changes in the hedging derivative over the life of the hedge relationship.

Once the forecast purchase is recognised and the hedge relationship has ended, the hedging instrument can then be designated in either a new fair value or cash flow hedge of the associated foreign currency trade payable for changes in foreign currency risk (see sections 5.1.2, 5.2.3 and 7.2.3 above). This would be a new hedge designation hence the issue of additional ineffectiveness associated with designating a hedging instrument that has a non-zero fair value might arise (see section 7.4.3 above). Illustration 7-18 below provides an example of the accounting for a cash flow hedge of a foreign currency trade receivable for changes in foreign currency risk. Alternatively, a choice could be made not to apply any further hedge accounting if the combination of accounting for the hedging derivatives at fair value through profit or loss and the IAS 21 retranslation of the trade payable provides sufficient natural offset (although fair value changes in the forward points are likely to result in some volatility in profit or loss).

Another alternative when hedging the foreign currency risk of a highly probable forecast purchase to the expected settlement date of the associated trade payable is to designate a cash flow hedge of both the foreign currency forecast purchase and associated foreign currency payable at the time the hedging instrument is transacted. However, this dual designation, whereby the documented hedged item changes from a highly probable forecast transaction to a recognised monetary item, does bring some additional complexity to the hedge relationship. Specifically, there is a need to calculate a change in value for each hedged item and allocate an appropriate share of the change in fair value of the hedging instrument to each hedged item.

The standard does not proscribe how to calculate the appropriate change in value of the hedged item and hedging instrument in a hedge of both the foreign currency forecast purchase and associated foreign currency payable. The IAS 39 Implementation Guidance includes an example of such a hedge, in which case all changes in value of the hedged item and hedging instrument are attributed to the 'live' element of the hedge relationship at any one time. [IAS 39.F.5.6]. So, until the forecast purchase is recognised, all changes in value are attributed to the hedge of the forecast purchase. Once the purchase is recognised and any remaining variability arises from the associated trade payable, all subsequent changes in value are attributed to the hedge of the trade payable. This approach is relatively simple, as it can be applied using only the actual hedged items and instruments, but it can result in an arbitrary allocation of the forward element (and foreign currency basis) of the hedging instrument to each hedged item, depending on prevailing market rates on the day the purchase is recognised.

Another potential method to assess the effectiveness and measure ineffectiveness in a hedge of both the foreign currency forecast purchase and associated foreign currency payable, is to notionally split the hedging instrument into the two phases of the hedge relationship and apply the usual hedge accounting requirements to each of the notionally split instruments (see section 3.6.2 above).

For example: a forecast foreign currency purchase is expected to occur on 30/6/20X2, the associated foreign currency trade payable is expected to settle on 30/9/20X2, and the hedging instrument (a forward foreign currency contract) matures on 30/9/20X2. In order to assess the effectiveness and measure ineffectiveness in the hedge relationship, both the hedged item and hedging instrument could be represented by a notional foreign currency forward contract maturing on 30/6/20X2 and a foreign currency swap with principal exchange on 30/6/20X2 and 30/9/20X2. (The combination of these matches the full hedged item and hedging instrument).

How we see it

We believe either of the above methods to allocate the change in value of the hedged item and hedging instrument in a hedge of both a foreign currency forecast purchase and associated foreign currency payable to be acceptable.

Notionally splitting the hedging instrument into the two phases of the hedge relationship is the more operationally complex of the two methods, as the accounting relies on instruments that have been notionally split. However, it does provide a more meaningful allocation of the forward element (and foreign currency basis) between the forecast purchase and the trade payable.

As noted above, some natural offset in profit or loss does occur when hedging the foreign currency risk in a foreign currency trade payable with a foreign currency forward contract. However, Illustration 7-18 below demonstrates how the accounting could be applied if designation in a hedge relationship is desirable.

Illustration 7-18: Cash flow hedge of foreign currency trade receivable

Company X has the Local Currency (LC) as its functional and presentation currency.

On 30 September 20X2, following the sale of inventory for FC500,000, X meets the criteria to recognize the associated revenue. Settlement for the sale is not due until 31 March 20X3, hence X also recognises a foreign currency trade debtor receivable due 31 March 20X3 at the transaction price of FC500,000. [IFRS 9.5.1.3].

X also enters into forward exchange contract to deliver Foreign Currency (FC) 500,000 and receive LC1,110,000 on 31 March 20X3 at an initial cost and fair value of zero. On inception, it designates the forward exchange contract as a hedging instrument in a cash flow hedge of the recognised foreign currency trade receivable. It is assumed that all hedge accounting conditions in IFRS 9 are met.

The relevant foreign currency rates and associated fair values for the forward exchange contract are provided in the following table:

Date	Spot rate	Forward rate to 31 March 20X3	Fair value of forward contract
30 September 20X2	2.20	2.22	-
31 December 20X2	2.40	2.41	(94,301)
31 March 20X3	2.35	-	(65,000)

For simplification purposes foreign currency basis risk is assumed to be zero. The applicable yield curve in the local currency is flat at 3% per annum throughout the period. The fair value of the forward exchange contract is negative LC94,301 on 31 December 20X2 ($\{[2.41 \times 500,000] - 1,110,000\} \div 1.34^{(3/12)}$), and negative LC65,000 on 31 March 20X3 ($2.35 \times 500,000 - 1,110,000$).

By transacting the forward exchange contract, X is now protected against changes in the spot rate of 2.20 on 30 September 20X2, and has locked in the forward points of LC10,000 (i.e., $([500,000 \times 2.2] - 1,110,000)$) within the forward exchange contract on that date.

Case 1: Changes in the spot element of the forward exchange contract only are designated in the hedge relationship (costs of hedging guidance is not applied)

Ignoring ineffectiveness that might arise from other elements that have an impact on the fair value of the hedging instrument, (such as foreign currency basis spreads (see section 7.4.8 below)), the hedge is expected to be fully effective because the critical terms of the forward exchange contract and the trade receivable are the same and the change in the forward element of the forward exchange contract is excluded from the assessment of effectiveness.

The assessment of hedge effectiveness is based on changes in the present value of the spot element. For this purpose, the spot element is calculated as the foreign currency cashflow translated at the prevailing spot rate on assessment date, less the deemed local currency cashflow as per spot rates on designation date. The present value is then calculated by discounting the spot element from the date the hedged item is expected to occur back to the assessment date, using discount factors derived from the applicable local currency yield curve. Changes in fair value of the excluded forward element are outside the hedge relationship and will be taken to profit or loss.

30 September 20X2		LC	LC
Dr	Trade receivable	1,100,000	
	Cr Revenue		1,100,000

To record the foreign currency trade receivable at the transaction price of FC500,000 using the prevailing spot rate (i.e., $500,000 \times 2.2 = LC1,100,000$). It is assumed that the requirements to recognise as revenue are met (see Chapter 28).

To record the forward exchange contract at its initial fair value, i.e., zero.

31 December 20X2		LC	LC
Dr	Trade receivable	100,000	
	Cr FX retranslation P&L		100,000

To remeasure the trade receivable to prevailing spot rate i.e., $[500,000 \times 2.4] - [500,000 \times 2.2] = LC100,000$. [IAS 21.28].

		LC	LC
Dr	OCI - cash flow hedge reserve	99,264	
Cr	Forward exchange contract - liability		94,301
Cr	Profit or loss (forward element)		4,963

To recognise the change in the fair value of the forward exchange contract between 30 September 20X2 and 31 December 20X2, i.e., $-94,301 - 0 = -\text{LC}94,301$. The change in the present value of spot element of the forward exchange contract is a loss of $\text{LC}99,264 = \{([2.4 \times 500,000] - 1,100,00) \div 1.03^{(3/12)}\} - \{([2.2 \times 500,000] - 1,100,00) \div 1.03^{(6/12)}\}$, which is recognised in OCI within the cash flow hedge reserve. The present value of the spot element of the forward exchange contract is calculated as there is a need to consider the time value of money when measuring hedge ineffectiveness (see section 7.4.2 above).

The second element of the above equation equals zero (i.e., $(2.2 \times 500,000) - 1,100,00 = 0$). This reflects the fact that the forward exchange contract is on market and accordingly has a zero present value on designation. Where this is the case, the calculation could be simplified as follows:

$$\{([2.4 \times 500,000] - 1,100,00) \div 1.03^{(3/12)}\} = \text{LC}99,264$$

The hedge is considered fully effective because the loss on the present value of the spot element of the forward exchange contract, $\text{LC}99,264$, exactly offsets the change in cash flows associated with the trade receivable based on spot rates price $\{([2.4 \times 500,000] - 1,100,000) \div 1.03^{(3/12)}\} - \{([2.2 \times 500,000] - 1,100,000) \div 1.03^{(6/12)}\} = \text{LC}99,264$. The positive figure denotes an increase in the net present value of cash inflows and, therefore, effectively represents a 'gain' to offset the loss on the forward exchange contract in OCI.

However, as the forward element is not part of the hedged risk, the change in the forward element of the forward exchange contract, a gain of $\text{LC}4,963 = -94,301 + 99,264$, is recognised in profit or loss. The forward element is calculated as the difference between the full fair value change in the forward exchange contract and the change in the present value of the spot element.

		LC	LC
Dr	FX retranslation P&L	100,000	
Cr	OCI - cash flow hedge reserve		100,000

To reclassify the effective portion of the change in spot element of the forward exchange contract from the cash flow hedge reserve to profit or loss as a reclassification adjustment in the same period(s) during which the hedged expected future cash flows affect profit or loss. Because the trade receivable is remeasured continuously in respect of changes in foreign currency rates per IAS 21, there is a requirement for the gain or loss on the forward contract to be reclassified from the cash flow hedge reserve to profit or loss as the receivable is remeasured, not when the payment occurs. The method used to facilitate the reclassification is not prescribed. (See section 7.2.3 above). Company X has chosen to immediately reclassify an amount equal to the IAS 21 retranslation on the trade receivable (see section 7.2.3 above), despite the fact that this is higher than the amount taken to OCI based on a discounted spot valuation. [IFRS 9.6.5.11(d)(ii), IAS 21.28].

		LC	LC
Dr	FX retranslation P&L	25,000	
Cr	Trade receivable		25,000

To remeasure the trade receivable to prevailing spot rate i.e., $[500,000 \times 2.35] - [500,000 \times 2.4] = -\text{LC}25,000$. [IAS 21.28].

		LC	LC
Dr	Forward exchange contract - liability	29,301	
Cr	OCI - cash flow hedge reserve		24,264
Cr	Profit or loss (forward element)		5,037

To recognise the change in the fair value of the forward exchange contract between 31 December 20X2 and 31 March 20X3, i.e., $-65,000 + 94,301 = \text{LC}29,301$. The change in the present value of spot element of the forward exchange contract is a gain of $\text{LC}24,264 = \{([2.35 \times 500,000] - 1,100,00)\} - \{([2.4 \times 500,000] - 1,100,00) \div 1.03^{(3/12)}\}$, which is recognised in OCI within the cash flow hedge reserve. The present value of the spot element of the forward exchange contract is calculated as there is a need to consider the time value of money when measuring hedge ineffectiveness (see section 7.4.2 above).

The hedge is considered fully effective because the gain on the forward exchange contract, $\text{LC}29,301$, exactly offsets the change in cash flows associated with the trade receivable based on the forward price $\{([2.35 \times 500,000] - 1,110,000)\} - \{([2.41 \times 500,000] - 1,110,000) \div 1.03^{(3/12)}\} = -\text{LC}29,301$. The negative figure denotes a decrease in the net present value of cash inflows and, therefore, effectively represents a 'loss' to offset the gain on the forward exchange contract in OCI.

Total	1,110,000	-	-	-	(10,000)

Case 2: Changes in the spot element of the forward exchange contract only are designated in the hedge relationship, the forward element is treated as a cost of hedging

Ignoring ineffectiveness that might arise from other elements that have an impact on the fair value of the hedging instrument, (such as foreign currency basis spreads (see section 7.4.8 below)), the hedge is expected to be fully effective because the critical terms of the forward exchange contract and the trade receivable are the same and the change in the forward element of the forward exchange contract is excluded from the assessment of effectiveness.

The assessment of hedge effectiveness is based on changes in the present value of the spot element. For this purpose, the spot element is calculated as the foreign currency cashflow translated at the prevailing spot rate on assessment date, less the deemed local currency cashflow as per the spot rate on designation date. The present value is then calculated by discounting the spot element from the date the hedged item is expected to occur back to the assessment date, using discount factors derived from the applicable local currency yield curve.

Changes in fair value of the excluded forward element are outside the hedge relationship and are treated as a cost of hedging a time related hedged item. [IFRS 9.6.5.15, IFRS 9.6.5.16]. (See section 7.5.1 below).

	30 September 20X2	LC	LC
Dr	Trade receivable	1,100,000	
	Cr Revenue		1,100,000

To record the foreign currency trade receivable at the transaction price of FC500,000 using the prevailing spot rate (i.e., $500,000 \times 2.2 = \text{LC}1,100,000$). It is assumed that the requirements to recognise as revenue are met (see Chapter 24).

	Cr FX retranslation P&L		100,000

To remeasure the trade receivable to prevailing spot rate
i.e., $[500,000 \times 2.4] - [500,000 \times 2.2] = \text{LC}100,000$. [IAS 21.28].

		LC	LC
Dr	OCI - cash flow hedge reserve	99,264	
	Cr Forward exchange contract - liability		94,301
	Cr OCI - separate component of equity (forward element)		4,963

To recognise the change in the fair value of the forward exchange contract between 30 September 20X2 and 31 December 20X2, i.e., $-94,301 - 0 = -\text{LC}94,301$. The change in the present value of spot element of the forward exchange contract is a loss of $\text{LC}99,264 = \{([2.4 \times 500,000] - 1,100,00) \div 1.03^{(3/12)}\} - \{([2.2 \times 500,000] - 1,100,00) \div 1.03^{(6/12)}\}$, which is recognised in OCI within the cash flow hedge reserve. The present value of the spot element of the forward exchange contract is calculated as there is a need to consider the time value of money when measuring hedge ineffectiveness (see section 7.4.2 above).

As noted above, the second element of the above equation equals zero (i.e., $(2.2 \times 500,000) - 1,100,00 = 0$). This reflects the fact that the spot element of the forward exchange contract is on market and accordingly has a zero present value on designation. Where this is the case, the calculation could be simplified as follows:
 $\{([2.4 \times 500,000] - 1,100,00) \div 1.03^{(3/12)}\} = \text{LC}99,264$.

The hedge is considered fully effective because the loss on the present value of the spot element of the forward exchange contract, $\text{LC}99,294$, exactly offsets the change in cash flows associated with the trade receivable based on spot rates, i.e., $\{([2.4 \times 500,000] - 1,100,000) \div 1.03^{(3/12)}\} - \{([2.2 \times 500,000] - 1,100,000) \div 1.03^{(6/12)}\} = \text{LC}99,294$. The positive figure denotes an increase in the net present value of cash inflows and, therefore, effectively represents a 'gain' to offset the loss on the forward exchange contract in OCI.

Applying the costs of hedging guidance to the forward element of the forward exchange contract: the change in the forward element (the change in fair value not designated as part of the hedged risk), a gain of $\text{LC}4,963 = -94,301 + 99,264$, is recognised in a separate component of equity.

In this example as the critical terms of the hedged item and hedging instrument match, the forward element is calculated as the difference between the full fair value change in the forward exchange contract and the change in the present value of the spot element.

Only the forward element that relates to the hedged item can be accumulated in a separate component of equity, therefore where differences exist between the hedged item and hedging instrument, there is a need to calculate the appropriate forward element using an aligned instrument based on the terms of the hedged item. (See section 7.5.1.A below).

Dr	FX retranslation P&L	100,000	
	Cr OCI - cash flow hedge reserve		100,000

To reclassify the effective portion of the change in spot element of the forward exchange contract from the cash flow hedge reserve to profit or loss as a reclassification adjustment in the same period(s) during which

the hedged expected future cash flows affect profit or loss. Because the trade receivable is remeasured continuously in respect of changes in foreign currency rates per IAS 21, there is a requirement for the gain or loss on the forward contract to be reclassified from the cash flow hedge reserve to profit or loss as the receivable is remeasured, not when the payment occurs. The method used to facilitate the reclassification is not prescribed. (See section 7.2.3 above). Company X has chosen to immediately reclassify an amount equal to the IAS 21 retranslation on the trade receivable, despite the fact that this is higher than the amount taken to OCI based on a discounted spot valuation. [IFRS 9.6.5.11(d)(ii), IAS 21.28].

	LC	LC
Dr OCl - separate component of equity (forward element)	5,000	
Cr FX retranslation P&L		5,000

To amortise the forward element at the time of designation as a (time-period related) cost of hedging on a systematic and rational basis over the period during which the trade receivable affects profit or loss. The amortisation is from the separate component of equity to profit or loss. The forward element at the time of designation is the locked in forward points within the forward exchange contract LC10,000 (i.e., $([500,000 \times 2.2] - 1,110,000)$), amortised on a straight line basis over the 6 months the trade receivable is live and affects profit and loss through the IAS 21 remeasurement. [IFRS 9.6.5.11(d)(ii)].

	LC	LC
Dr FX retranslation P&L	25,000	
Cr Trade receivable		25,000

To remeasure the trade receivable to prevailing spot rate i.e., $[500,000 \times 2.35] - [500,000 \times 2.4] = -\text{LC}25,000$. [IAS 21.28].

	LC	LC
Dr Forward exchange contract - liability	29,301	
Cr OCl - cash flow hedge reserve		24,264
Cr OCl - separate component of equity (forward element)		5,037

To recognise the change in the fair value of the forward exchange contract between 31 December 20X2 and 31 March 20X3, i.e., $-65,000 + 94,301 = \text{LC}29,301$. The change in the present value of spot element of the forward exchange contract is a gain of LC24,264 = $\{([2.35 \times 500,000] - 1,100,000)\} - \{([2.4 \times 500,000] - 1,100,000) \div 1.03^{(3/12)}\}$, which is recognised in OCl within the cash flow hedge reserve. The present value of the spot element of the forward exchange contract is calculated as there is a need to consider the time value of money when measuring hedge ineffectiveness (see section 7.4.2 above).

The hedge is considered fully effective because the gain on the forward exchange contract, LC29,301, exactly offsets the change in cash flows associated with the trade receivable based on the forward price $\{([2.35 \times 500,000] - 1,110,000)\} - \{([2.41 \times 500,000] - 1,110,000) \div 1.03^{(3/12)}\} = -\text{LC}29,301$. The negative figure denotes a decrease in the net present value of cash inflows and, therefore, effectively represents a 'loss' to offset the gain on the forward exchange contract in OCl.

		LC	LC
Dr	Forward exchange contract - liability	65,000	
	Cr Cash		65,000

To record the net settlement of the forward exchange contract.

Ultimately LC1,110,000 of cash was received, representing the 2.22 forward foreign currency rate achieved through the forward exchange contract, with the locked in forward points from the forward exchange contract when transacted recognised in profit or loss on a rational and systematic basis as a cost of hedging.

A summary of the accounting entries is shown below:

DR/(CR)	Cash	Forward exchange contract	Receivable	OCI	Equity	Profit of Loss
	LC	LC	LC	LC	LC	LC
30/09/20X2						
Record receivable			1,100,000			
31/12/20X2						
Change in FV		(94,301)		99,264	(4,963)	
IAS 21 remeasure			100,000			(100,000)
Reclassification				(100,000)		100,000
Cost of hedging					5,000	(5,000)
31/03/20X3						
Change in FV		29,301		(24,264)	(5,037)	
IAS 21 remeasure			(25,000)			25,000
Reclassification				25,000		(25,000)
Cost of hedging					5,000	(5,000)
Settle receivable	1,175,000		(1,175,000)			
Settle forward	(65,000)	65,000				
Total	1,110,000	-	-	-	-	(10,000)

In both these examples we have ignored foreign currency basis risk (see section 7.4.8 below), however, if we were to consider it, additional volatility in profit or loss may arise in Case 1, as foreign currency basis is not part of the hedged risk therefore any fair value changes in the hedging instrument due to foreign currency basis are not replicated in the hedged item. In Case 2 the calculation method for the forward element would by default also include any foreign currency basis, i.e., the 'residual' after the spot element is deducted from the full fair value changes. However, foreign currency basis could be considered part of cost of hedging, similar to the forward element. [IFRS 9.6.5.16].

Unlike in Illustration 7-17 above, we have not provided a comparison of a designation of the forward element when hedging the foreign currency risk in a foreign currency trade payable/receivable. This is because the designation as per Case 2: where only the spot element of the forward exchange contract is designated in the hedge relationship, with the forward element treated as a cost of hedging, appears to be what the IASB had in mind for such hedge relationships (see section 7.5.2 below). [IFRS 9.BC6.422]. However, we are aware that designation of the forward element when hedging a currency foreign currency trade payable/receivable does occur in practice, despite the resulting ineffectiveness (see section 7.2.3 above).

7.4.8 Foreign currency basis spreads

One phenomenon of the 2007/8 financial crisis was the increase in foreign currency basis spreads. The foreign currency basis is the charge above the risk-free rate in a foreign country to compensate for country and liquidity risk. Historically, basis spreads had been low, but increased significantly after the financial crisis and the following sovereign debt crisis. Volatility in foreign currency basis can create hedge ineffectiveness when using a cross-currency interest rate swap (CCIRS) to hedge the foreign currency and interest rate risk of a debt instrument issued in a foreign currency.

When designating the CCIRS in a fair value hedge, the gain or loss on the hedged item attributable to changes in the hedged interest rate risk is determined based on the foreign currency interest rate curve, therefore excluding currency basis. IAS 21 then requires such a monetary item in a foreign currency to be translated to the functional currency using the spot exchange rate. [IAS 21.23]. Conversely, the fair value of the CCIRS incorporates the foreign currency basis spread which results in ineffectiveness.

For a cash flow hedge, IFRS 9 is explicit that when using a hypothetical derivative to calculate ineffectiveness, the hypothetical derivative cannot simply impute a charge for exchanging different currencies (i.e., the foreign currency basis spread) even though actual derivatives (for example, cross-currency interest rate swaps) under which different currencies are exchanged might include such a charge (see section 7.4.4 above). [IFRS 9.B6.5.5].

Although cross-currency interest rate swaps are used to highlight the fact that foreign currency basis spreads must not be replicated in hypothetical derivatives, this issue is also likely to arise in other foreign currency contracts settled in the future. This is also an issue for net investment hedges for which the hedging instrument is a derivative (see Illustration 7-9 in section 7.3.3.B above and section 7.5.3 below).

To address this, IFRS 9 identifies foreign currency basis spread as a 'cost of hedging'. Application of the costs of hedging accounting permits an appropriate portion of the change in the fair value of foreign currency basis spread to be taken to OCI rather than immediately recognised in profit or loss, see section 7.5.3 below.

7.4.9 The impact of the hedging instrument's credit quality

One of the key hedge effectiveness requirements in IFRS 9 is that the impact of credit risk must not be of a magnitude such that it dominates the value changes (see section 6.4.2 above). [IFRS 9.6.4.1(c)(ii)]. It is therefore clear that the credit quality of the hedging instrument, and hedged item are both relevant in determining the ongoing eligibility of a hedge relationship. However, the assessment of the effect of credit risk on value changes for hedge effectiveness purposes, which often can be made on a qualitative basis, must not be confused with the requirement to measure and recognise the impact of credit risk on the hedging instrument and, where appropriate, the designated hedged item, which will normally give rise to hedge ineffectiveness recognised in profit or loss (see sections 7.4.1 and 7.4.5 above).

Hedge ineffectiveness is the extent to which the changes in the fair value or cash flows of the hedging instrument are greater or less than those on the hedged item. [IFRS 9.B6.4.1]. Although it is permissible to exclude some components from a designated hedging instrument, and associated fair value changes, counterparty credit risk is not one of the permitted exclusions (see section 3.6 above). Accordingly, unless the hedged item attracts the same credit risk as the hedging instrument, it will be a source of ineffectiveness (see section 7.4.1 above). In practice, it is very unlikely to be the case that the hedged item and hedging instrument both attract the same credit risk. In particular, they will often not share the same counterparty, credit enhancement arrangements, term, exposure to credit risk and in a highly probable forecast transaction there could be no credit risk at all (see section 6.4.2.B above). In addition to changes in the hedging instrument's counterparty credit risk, changes in the reporting entity's own credit risk might also affect the fair value of the hedging instrument in ways that are not replicated in the hedged item (see Chapter 15).

For a fair value hedge, the implications of this requirement are clear. If there is a change in the hedging instrument's credit risk, the hedging instrument's fair value will change, but there is unlikely to be an offsetting change in fair value for the hedged item. This will affect its effectiveness as measured. In most cases, credit risk in the hedged item does not form part of the designated hedged risk (see section 2.2 above) and so changes in fair value of the hedged item due to credit risk will not provide any offset to changes in the fair value of the hedging instrument due to its credit risk. However, as noted above, even if credit risk is not part of the designated risk, if changes in the fair value of the hedged item due to credit risk dominate the value changes in the hedge relationship, then the hedge must be discontinued (see section 6.4.2.B above and section 8.3 below).

For a cash flow hedge, the implications might not immediately be so obvious. It is relatively common for the measurement of ineffectiveness in a cash flow hedge to be calculated using a hypothetical derivative (see section 7.4.4 above). Hence, the effect of changes in the hedging instrument's credit risk on the measurement of ineffectiveness might be best explained in the context of a hypothetical derivative. The application guidance of IFRS 9 states that when applying the hypothetical derivative method, one cannot include features in the value of the hedged item that only exist in the hedging instrument, but not in the hedged item. [IFRS 9.B6.5.5].

Given the prohibition on reflecting terms in the hypothetical derivative that do not exist in the hedged item, it is clear that, when using a hypothetical derivative for measuring ineffectiveness in a cash flow hedge, the counterparty credit risk on the hedging instrument will not, as a matter of course be deemed to be equally present in the hedged item (see section 7.4.5 above). [IFRS 9.B6.5.5]. For example, if the hedged item is a highly probable forecast transaction it might not involve any credit risk at all (see section 6.4.2.B above), so that there is no offset for the specific credit risk affecting the fair value of the hedging instrument. This would give rise to some ineffectiveness recorded in profit or loss.

The impact will be more pronounced where the hedging instrument is longer term, has a significant fair value and there exist no other credit enhancements such as collateral agreements or credit break clauses.

Nowadays, many derivative contracts between financial institutions are cash collateralised (see section 8.3.5 below) or settled-to-market (STM). For STM derivatives, the daily variation margin is used to settle the derivative's outstanding fair value position (see section 8.3.6 below). Both cash collateralisation and STM significantly reduces the credit risk for both parties involved. Accordingly, the residual credit risk due to these cash collateralised and STM derivatives is much less likely to be a significant source of ineffectiveness than for uncollateralised derivatives in the past.

7.4.10 Ineffectiveness from the most recently fixed variable leg of the hedging derivative

When measuring ineffectiveness in hedge relationships for which the designated hedging instruments is an interest rate swap or similar, fair value 'noise' is often generated between the dates on which the variable leg is reset to market, in particular for a fair value hedge. Currently the payments on an interest rate swap are typically established at the beginning of a reset period and paid at the end of that period. Between these two dates the swap is no longer a pure pay-fixed receive-variable (or *vice versa*) instrument because both the next payment and the next receipt are fixed. Accordingly, the corresponding changes in the fair value of the hedged item (e.g., fixed rate debt) will not strictly mirror that of the swap. This problem becomes more acute the less frequently variable interest rates are re-fixed to market rates.

This 'noise' is unlikely to be significant enough to influence whether there is an economic relationship or not, especially where the interval between re-pricings is frequent enough, e.g., quarterly rather than annual, in order to minimise the changes in fair value from the fixed net settlement or next interest payment (see section 6.4.1 above). However, ineffectiveness must always be measured and recognised in profit or loss (see section 7.4 above). This ineffectiveness is likely to be more significant when interest rates are more volatile, as experienced by a number of entities during the financial crisis starting in the second half of 2007.

However, as a result of the reforms mandated by the Financial Stability Board following the Financial Crisis, less fair value sensitivity is expected as IBORs are being replaced by new 'official' benchmark rates, known as RFRs. At the time of writing, most derivative RFRs are expected to be a compounded RFR rate with regular settlements (e.g., a rate equal to daily cumulative accrual at the overnight RFR rate, settled every 3 months). Some term rates do exist, but for example the U.S. Alternative Reference Rates Committee has recommended that the use of Term SOFR should be limited to specific purposes (see the *Supplement: IBOR Reform*).

Where a cumulative accrual RFR is applied this will reduce or fully eliminate the 'noise' from the revaluation of the floating leg, as the floating rate never becomes 'fixed' given the ongoing cumulative accrual at the prevailing overnight rate.

7.4.11 Effectiveness of options

It was explained in section 3.6.4 above that the time value of an option can be excluded from the hedge relationship and treated as a cost of hedging (see section 7.5 below). In many cases excluding the time value of an option could make it easier to demonstrate an expectation of offset from changes in the hedged item and the hedging instrument in the determination of the existence of an economic relationship (see section 6.4.1 above). In such cases, if the documented hedged risk is appropriately customised there will, in many cases, be very little ineffectiveness to recognise (other than for example that arising from changes in credit risk, basis risk or other terms that are not aligned between the hedged item and hedging option), as set out in the following illustration.

Illustration 7-19: Out of the money put option used to hedge forecast sales of commodity

Company A expects highly probable forecast sales of 100 tonnes of commodity X in 6 months' time. The current unit price of commodity X is £100 per tonne. To partially protect itself against a decrease in the price of the commodity, A acquires a put option, which gives it the right to sell 100 tonnes of commodity X at £90 per tonne. Company A's objective is only to provide protection for price changes below £90 per tonne, and such a strategy is often referred to as a hedge of a one-sided risk. [IFRS 9.B6.3.12].

A is permitted to designate changes in the option's intrinsic value as the hedging instrument to reflect the one-sided risk in the hedged item. The changes in the intrinsic value of the option provide protection against the risk of variability in the price of commodity X below or equal to the strike price of the put of £90 per tonne. For prices above £90 per tonne, the option is out of the money and has no intrinsic value. Accordingly, gains and losses on the forecast sales of commodity X for prices above £90 are not attributable to the hedged risk for the purposes of assessing whether an economic relationship exists or not, nor are they relevant when measuring ineffectiveness. [IFRS 9.B6.3.11].

Therefore, when calculating the cumulative change in present value of the hedged forecast sales for the purposes of measuring ineffectiveness, no present value change would arise for variation in the price of commodity X above £90 per tonne. Changes in the fair value (present value) of the hedged forecast sales associated with price declines below £90 per tonne form part of the designated cash flow hedge and hence are included within the calculation of ineffectiveness. This can be achieved using a hypothetical derivative taking the form of the intrinsic value of a hypothetical option contract to represent the one-sided risk (see Illustration 7-14 in section 7.4.4 above).

Assuming there are no sources of ineffectiveness (i.e., including no change in credit risk), those changes are offset by changes in the intrinsic value of the put, resulting in zero ineffectiveness to be recognised in profit or loss (see section 7.2 above).

Changes in the time value of the put option are excluded from the designated hedging relationship and the costs of hedging guidance is applied (see section 7.5.1 below).

When hedging a one-sided risk, the hedged risk cannot include the time value of a purchased option, because the time value is not a component of the forecast transaction. [IFRS 9.B6.3.12]. Hence if, a purchased option is designated in its entirety as the hedging instrument of a one-sided risk arising from a forecast transaction, additional ineffectiveness will arise, as changes in the fair value of the hedged item will not provide any offset to changes in time value of the hedging instrument. This is consistent with the Implementation Guidance on hypothetical derivatives in IFRS 9 that prohibits the inclusion of features in the value of the hedged item that only exist in the hedging instrument (see section 7.4.4 above). [IFRS 9.B6.5.5].

7.4.12 Hedged items with embedded optionality

As described in section 3.6.4 above, an entity can exclude the time value of the hedging instrument from the hedging relationship when hedging with options. Changes in value of the excluded time value must then be treated as a cost of hedging (see section 7.5 below). Such a strategy is sometimes applied when hedging highly probable forecast cash flows, in which case excluding the time value of the hedging option would most likely achieve a lower level of ineffectiveness from an accounting perspective (see section 7.4.11 above).

However, if the hedged item contains embedded optionality which is matched by optionality within the hedging instrument, including the time value from both the hedged item and hedging instrument in the hedge relationship could result in good levels of offset from the change in value of the hedged item and hedging instrument. This is because there will be a level of offset from changes in the time value of the hedging option and changes in the embedded time value in the hedged item. The following fact patterns provide examples of where there might be offsetting changes in time value:

- Entity A has purchased 10-year fixed rate debt. At the end of years five and seven, the issuer has the option to prepay the debt at par. Entity A could choose to eliminate variability in the fair value of the fixed rate debt by transacting a pay fixed receive floating interest rate swap, with matching prepayment options at five and seven years.
- Entity B has issued floating rate debt which includes an embedded floor (e.g., interest is floored at 0%). Entity B could choose to eliminate the variability in the cash flows above the floor (and lock in current low rates), by transacting a pay fixed and receive floating swap with an embedded floor.

In the case of Entity A above, it is relatively easy to conclude that the change in value of the embedded prepayment option must form part of the effectiveness assessment and measurement of ineffectiveness, as a fair value hedge. However, it is less clear in the case of Entity B since the arrangement would be a cash flow hedge.

IFRS 9 provides guidance on hedge accounting for purchased options hedging a one-sided risk in a forecast transaction. The guidance explains that only the intrinsic value of the option and not the option time value will represent the hedged item because time value is not a component of the forecast transaction that affects profit or loss. Therefore, if an entity designates a purchased option in its entirety, as the hedging instrument of a one-sided risk arising from a forecast transaction, the hedging relationship will not be perfectly effective. In this situation, there will be no offset between the cash flows relating to the time value of the option premium paid and the designated hedged risk. [IFRS 9.B6.3.12].

How we see it

The guidance mentioned above on accounting for purchased options hedging a one-sided risk might be read not to permit including the change in the time value of an embedded option in a hedged item as part of the change in value of the hedged item when measuring ineffectiveness. However, the above guidance was written specifically for forecast transactions that do not include time value, whereas hedged items with embedded optionality do include time value. Therefore, we do not believe that IFRS 9 includes a prohibition on including option time value as part of the change in value of a hedged item that includes optionality.

A further requirement is that a cash flow hedge is a hedge of an exposure to variability in cash flows that could affect profit or loss. [IFRS 9.6.5.2(b)]. Arguably, a change in the time value of an embedded option within the hedged item does not affect profit or loss, nor does it result in cash flow variability.

How we see it

We believe that cash flow variability and the potential to affect profit or loss must be demonstrated for the designated hedged risk at the level of the hedged cash flows and not for other factors affecting the fair value of the hedged risk. However, the measurement of ineffectiveness must incorporate the cumulative change in fair value (present value) of the expected future cash flows of the entire hedged item, with respect to the designated hedged risk. The fair value of the hedged cash flows, which include the embedded optionality, includes the time value and not just the intrinsic value.

Further support for the above view is provided by the requirement that, when measuring ineffectiveness, it is not acceptable only to compare the cash flows of the hedged item and hedging instrument, since it is also necessary to consider the time value of money by discounting those cash flows. [IFRS 9.B6.5.4]. This is despite the fact that the time value of money does not affect profit or loss or cause variability in the cash flows in a cash flow hedge, but is considered a factor in the cumulative fair value (present value) of the future cash flows (consistent with IFRS 9.6.5.11(a)(ii)). This is also consistent with the requirement that the time value of any embedded optionality within the hedged item with respect to the hedged risk must be considered when measuring ineffectiveness, irrespective of whether the associated hedging instrument also has optionality. For a cash flow hedge, this can be achieved by using a hypothetical derivative that also reflects the embedded optionality (see section 7.4.4 above).

Other risk management strategies might arise whereby hedged items with optionality are economically hedged using hedging instruments without optionality, such as hedging floored or prepayable debt instruments against changes in interest rates using vanilla interest rate swaps. In that case it is not permitted to isolate only certain features in the hedged item that contribute to the change in fair value (present value) due to the hedged risk (e.g., interest rate risk) in order to better match the features of the hedging instruments. All the features of the hedged item whose fair value is affected by changes in the hedged risk must be included in the hedge relationship, otherwise the measurement of hedge effectiveness would not include the full fair value change with respect to the hedged risk. [IFRS 9.BC6.204].

Instances could arise whereby the fair value of the embedded option clearly varies due to factors other than the hedged risk. For example, in the case of prepayable mortgages the fair value of the embedded prepayment option might change due to a shift in house prices, tax regime or other regulations. Where a specified risk component is designated, only changes in the fair value of the embedded option due to changes in the specified risk component are included as part of the change in value of the hedged item (see section 2.2.1 above). [IFRS 9.B6.3.11, IFRS 9.B6.4.1]. However, if there is uncertainty as to the factors that gave rise to the change in fair value of an embedded option, or it is not possible to separate reliably the change that arises from the hedged risk from changes relating to other factors, then the change is assumed to arise from the hedged risk. [IAS 39.AG121]. Further, where changes in the other factors (i.e., not the specified risk component) result in actual changes to the hedged cash flows, that cannot be ignored for hedge accounting purposes, in particular if the hedged cash flows no longer exists as a result.

7.5 Accounting for the costs of hedging

From a risk management perspective, entities typically consider the premium paid on an option (which, on inception, is often only time value), the forward element in a forward contract and any foreign currency basis spread, as a cost of hedging rather than a trading position. Economically, these 'costs' could be considered as a premium for protection against risk (i.e., an 'insurance premium'). [IFRS 9.BC6.387]. The IASB acknowledged these concerns when developing IFRS 9 and included a specific accounting treatment for changes in the fair value of the time value of an option contract, the forward element in a forward contract and foreign currency basis spread, to be excluded from the hedging instrument (see section 3.6 above) and treated separately. [IFRS 9.6.2.4].

The excluded forward elements of forward contracts and foreign currency basis spreads can either remain at fair value through profit or loss, or be treated as 'costs of hedging', however, for the excluded time value of options the latter treatment is mandated. The 'costs of hedging' guidance in IFRS 9 is included in IFRS 9.6.5.15 and 6.5.16 and the associated application guidance in IFRS 9.B6.5.29 to 39. It must not be used by analogy more widely to exclude other portions not explicitly identified in the guidance (see section 3.6 above). [IFRS 9.BC6.297].

On application of the costs of hedging accounting, fluctuations over time in the fair value of the time value of options, the forward element of forward contracts or foreign currency basis spreads, is recorded in other comprehensive income instead of affecting profit or loss immediately. Although the costs of hedging will ultimately be recognised in profit or loss, this will be in a manner consistent with the risk management activity.

It is important to note that because this accounting for 'costs of hedging' only applies if the time value of the option, the forward element of forward contracts or foreign currency basis spreads are excluded from the designation of the hedging relationship, the amounts deferred in other comprehensive income are not part of the cash flow hedge (or foreign currency reserve) but instead a different component of equity. The cash flow hedge reserve (or foreign currency reserve) only includes amounts that are gains or losses on hedging instruments that are determined to be an effective hedge (i.e., amounts that are included in the designation of a hedging relationship) (see section 7.4 above).

7.5.1 Time value of options

The fair value of an option consists of its intrinsic value and its time value. An entity can either designate an option as a hedging instrument in its entirety, or it can separate the intrinsic value and the time value and designate only the intrinsic value (see section 3.6.4 above). [IFRS 9.6.2.4(a)].

If the option is designated in its entirety as a hedge of a non-option item, changes in the portion of the fair value attributable to the option time value result in ineffectiveness (see section 7.4.11 above). This is because only changes in the intrinsic value of the option will provide offset to the fair value changes attributable to the hedged risk. (The situation is different if the hedged item also includes optionality, see section 7.4.12 above, or if a delta-neutral hedging strategy is applied, see section 6.3.2 above). Depending on the level of ineffectiveness from changes in the time value, an entity could have difficulty determining that there is an economic relationship between the hedged item and the hedging option (see section 6.4.1 above).

If an entity chooses to exclude the time value from the designated hedging instrument it must apply the costs of hedging guidance, such that changes in the fair value of the time value of options (to the extent that they relate to the hedged item) are first recognised in OCI. Calculation of the extent to which the fair value changes relate to the hedged item requires the determination of a theoretical 'aligned instrument' based on the hedged item (see section 7.5.1.A below). [IFRS 9.6.5.15]. It is worth noting that this treatment is not an accounting policy choice, as the treatment must be applied for all hedge relationships for which only the intrinsic value of the hedging option is designated within the hedge relationship. The subsequent treatment depends on the nature of the hedged transaction.

The standard differentiates between transaction related hedged items and time-period related hedged items: [IFRS 9.6.5.15, IFRS 9.B6.5.29]

- Transaction related hedged items: the time value of an option used to hedge such an item has the character of part of the cost of the transaction. Examples would be a hedge of forecast purchases of inventory or property, plant and equipment, and forecast sales or purchases, as well as purchases or sales resulting from firm commitments. It would also include hedging the foreign currency risk in a forecast acquisition of a business (see section 2.6.4 above).

The amount that is accumulated in OCI is removed similarly to amounts accumulated in the cash flow hedge reserve (see section 7.2.2 above).

So if the hedged transaction subsequently results in the recognition of a non-financial item (e.g., purchase of inventory or property, plant and equipment) the amount becomes a 'basis adjustment' (see Illustration 7-17 Case 3 in section 7.4.7 above for a worked example). This treatment is also applied in the hedge of a forecast business acquisition (see section 7.6 below).

For other hedged transactions (e.g., forecast sales) the amount is reclassified to profit or loss in the same period or periods during which the hedged cash flows affect profit or loss.

- Time-period related hedged items: the time value of an option used to hedge such an item has the character of the cost of protection against a risk over a particular period of time (rather than a hedge of a transaction for which the transactions costs are accounted for as part of a one-off event).

The amount that will be accumulated in OCI is amortised on a systematic and rational basis to profit or loss as a reclassification adjustment (see Illustration 7-18 Case 2 in section 7.4.7 above for a worked example). The amortisation period is the period during which the hedge adjustment for the option's intrinsic value could affect profit or loss (or other comprehensive income if the option is designated as the hedging instrument in a fair value hedge of an equity instrument accounted for at fair value through other comprehensive income (see section 2.6.3 above)). The appropriate amortisation period is illustrated in Illustration 7-20 below. [IFRS 9.6.5.15].

Examples of time-period related hedged items are hedges of interest expense or income in particular periods, already purchased inventory hedged for fair value changes, or a hedge of a net investment in a foreign operation. In the case of a forward starting interest rate option, the time value would be amortised over the interest periods that the option covers (i.e., the amortisation period would exclude the initial part of the option's life). [IFRS 9.B6.5.30].

Illustration 7-20: Amortisation of time value of an option hedging a time-period related hedged item

If an interest rate option (a cap) is used to provide protection against increases in the interest expense on a floating rate bond, and for which the critical terms of the option and hedged item match, the time value of the cap is amortised to profit or loss as follows:

- If the cap hedges increases in interest rates for the first three years out of a total life of the floating rate bond of five years, the time value of that cap is amortised over the first three years.
- Or
- If the cap is a forward starting option that hedges increases in interest rates for years two and three out of a total life of the floating rate bond of five years, the time value of that cap is amortised during years two and three. [IFRS 9.B6.5.30].

By default, the time value will be zero at expiry of an option contract. For a transaction related hedged item, recognising the fair value changes of the time value in OCI means that on expiry, the aligned time value (i.e., the time value associated with the theoretical aligned instrument) that existed at designation will have accumulated in OCI (see section 7.5.1.A below). As mentioned above, once the hedged transaction happens, the accounting for the accumulated time value follows the accounting for any changes in fair value of the intrinsic value of the option recorded in the cash flow hedge reserve. [IFRS 9.6.5.15(b)]. Illustration 7-21 below illustrates how the costs of hedging accounting might be applied for a transaction related hedged item.

Illustration 7-21: Hedging the purchase of equipment (transaction related)

In the first quarter of a year, a manufacturing entity plans to purchase a new machine for its manufacturing process. Delivery of the machine is expected in the third quarter and the purchase price will be Swedish Krona (SEK) 5m. The entity has the Norwegian Krone (NOK) as its functional currency and, therefore, is exposed to foreign currency risk on this forecast transaction. The entity buys a call option to purchase SEK 5m in the third quarter, as it wishes to hedge the downside risk only. The terms of the option match the terms of the forecast transaction. The entity designates only the intrinsic value of the call option in a cash flow hedge of the highly probable forecast purchase of the machine.

At inception, the time value of the option amounts to NOK 30,000. The time value of the option amounts to NOK 16,000 at the end of the first quarter, NOK 7,000 at the end of the second quarter and zero at maturity. Applying the IFRS 9 accounting requirements to the time value of the option results in the following movement within other comprehensive income (OCI), specifically the reserve within equity for accumulating amounts in relation to the time value of options associated with transaction related hedged items:

(All amounts in NOK thousands)	Q1	Q2	Q3
Reserve at beginning of quarter	-	(14)	(23)
Change in time value of option	(14)	(9)	(7)
Basis adjustment to machine			30
Reserve at end of quarter	(14)	(23)	-
Effect on OCI for the period	(14)	(9)	23

In the illustration above, the critical terms of the actual option match the terms of the forecast transaction and so the aligned time value matches that of the actual option. Consequently, the full change in the actual time value is taken to OCI as a cost of hedging. This will not always be the case, so it cannot be assumed that the aligned time value equals the actual time value (see section 7.5.1.A below).

As noted above, by default, the time value will be zero at expiry of an option contract. For a time-period related hedged item, recognising the fair value changes of the time value in OCI means that on expiry, the time value that existed at designation will have accumulated in OCI. For time-period related hedged items, the amount accumulated in OCI is amortised on a 'systematic and rational basis' to profit or loss, however the standard does not prescribe what on a 'systematic and rational basis' means in this context.

[IFRS 9.6.5.15(c)]. A straight-line amortisation is likely to be appropriate in most cases.

Illustration 7-22: Hedging interest rate risk of a bond (time-period related) (1)

An entity issues a seven-year floating rate bond and wishes to protect itself against increases in the interest expense for the first two years. Therefore, the entity purchases an interest rate cap with a maturity of two years. The terms of the option match all other terms of the floating rate bond. Only the intrinsic value of the cap is designated as a hedging instrument in a cash flow hedge.

The time value on designation is CU20, which is amortised to profit or loss on a straight-line basis over the protection period (i.e., the first two years). The time value of the option amounts to CU13 at the end of the first year and zero at maturity.

Applying the IFRS 9 accounting requirements to the time value of the option results in the following movement within other comprehensive income (OCI), specifically the reserve within equity for accumulating amounts in relation to the time value of options associated with time-period related hedged items:

	Year 1	Year 2
Reserve at beginning of year	-	3
Change in time value of option	(7)	(13)
Amortisation of time value at inception	10	10
Reserve at end of year	3	-
Effect on OCI for the year	3	(3)
Effect on profit or loss for the year	(10)	(10)

How we see it

The standard is not prescriptive as to where in profit or loss the costs of time-period hedges accumulated in OCI is recycled. If the time value is considered akin to an insurance premium (the 'insurance premium view' mentioned previously (see section 7.5 above)), then it would follow that the cost could be reflected in the same line as profit or loss on the hedged item is recorded. This would be an accounting policy choice since the standard is not clear. However, when hedging forecast sales or purchases, one acceptable treatment would be presentation within the financial expense/income line item.

If hedge accounting is discontinued for a time-period related hedge relationship for which the costs of hedging treatment has been applied to the time value of the hedging option, the net amount (i.e., including cumulative amortisation) that has been accumulated in OCI must be immediately reclassified to profit or loss as a reclassification adjustment. This appears to be the case whether or not the hedged item is still expected to occur. This would reflect that the reason for amortising the amount would no longer apply after the insured amount (i.e., the hedged item) no longer qualifies for hedge accounting. [IFRS 9.6.5.15(c), IFRS 9.BC6.399]. In contrast, there is no equivalent guidance for discontinuation of transaction related hedges when the transaction is still expected to take place, and so there does not seem to be a need to reclassify the net amount accumulated in OCI immediately to profit or loss in that scenario. However, consideration as to the recoverability of amounts in other comprehensive income with respect to transaction related hedges might be required (see section 7.2.1 above). [IFRS 9.BC6.399].

The accounting for the time value of options would also apply to combinations of options, for example, when hedging a highly probable forecast transaction with a zero-cost collar. When designating the intrinsic value only, the volatility resulting from changes in the time values of the two options would be recognised in other comprehensive income. However, the amortisation (in the case of time-period related hedged items) or the transaction costs deferred at the end of the life of the hedging relationship (for transaction related hedged items) would be nil when using a zero-cost collar, as the cumulative change in time value over the period would be nil. [IFRS 9.B6.5.31].

7.5.1.A Aligned time value

Illustration 7-21 and Illustration 7-22 above both assume that the critical terms of the option match the hedged item. However, in practice, this is not always the case. The accounting treatment described above applies only to the extent the time value relates to the hedged item. Accordingly, an additional assessment has to be made if the critical terms of the option do not match the hedged item, to determine the extent to which this is the case. For that purpose, the actual time value has to be compared with that of a hypothetical option that perfectly matches the critical terms of the hedged item (in IFRS 9 referred to as the 'aligned time value'). [IFRS 9.B6.5.32].

When the terms of the option are not aligned with the hedged item, the accounting for the time value in situations in which the aligned time value exceeds the actual time value is different to situations in which the actual time value exceeds the aligned time value. [IFRS 9.B6.5.33].

If, at inception, the actual time value exceeds the aligned time value:

- The aligned time value at inception is treated in line with the general requirements outlined in section 7.5.1 above, depending on whether it is a time period or transaction related hedged item
 - The change in the fair value of the aligned time value is recognised in OCI
- And
- The remaining difference in change in fair value between the actual time value and the aligned time value is recognised in profit or loss

If, at inception, the aligned time value exceeds the actual time value:

- The actual time value at inception is treated in line with the general requirements outlined in section 7.5.1 above, depending on whether it is a time period or transaction related hedged item except as follows:
 - The lower of the cumulative change in the fair value of the actual time value and the aligned time value is recognised in OCI

And

- The remaining difference in change in fair value between the actual time value and the aligned time value, if any, is recognised in profit or loss [IFRS 9.B6.5.33]

For the hedging strategy introduced in Illustration 7-22 above, this would change the accounting as follows:

Illustration 7-23: Hedging interest rate risk of a bond (time-period related) (2)

Scenario 1: Actual time value exceeds aligned time value

The actual time value at inception is CU20, and over time follows the same pattern as in Illustration 7-22 above. The aligned time value at inception is CU15. The aligned time value of the option amounts to CU9 at the end of the first year and zero at maturity.

	Year 1	Year 2
Change in actual time value of option	(7)	(13)
Change in aligned time value of option	(6)	(9)
Reserve in equity at beginning of year	-	1.5
Change in time value of option (based on aligned time value)	(6)	(9)
Amortisation of time value at inception (based on aligned time value)	7.5	7.5
Reserve in equity at end of year	1.5	-
Effect on OCI for the year	1.5	(1.5)
Remaining change in (actual) time value recognised in profit or loss (difference between the change in aligned time value and the actual time value of the option)	(1)	(4)
Effect on profit or loss for the year	(8.5)	(11.5)

The above accounting treats the difference between the actual and the aligned time value, consistent with its default classification, as a derivative at fair value through profit or loss.

Scenario 2: Actual time value is lower than aligned time value

The actual time value at inception is CU20, and over time follows the same pattern as in Illustration 7-22 above. The aligned time value at inception is CU24. The aligned time value of the option amounts to CU10 at the end of the first year and zero at maturity.

	Year 1	Year 2
Change in actual time value of option	(7)	(13)
Change in aligned time value of option	(14)	(10)
Reserve in equity at beginning of year	-	3
Change in time value of option (based on the lower of the cumulative change in aligned time value and actual time value)	(7)	(13)
Amortisation of time value at inception (based on actual time value)	10	10
Reserve in equity at end of year	3	-
Effect on OCI for the year	3	(3)
Remaining change in (actual) time value recognised in profit or loss (zero, because the aligned time value of the option exceeds the actual time value of the option at inception)	-	-
Effect on profit or loss for the year	(10)	(10)

The above 'lower of test' for the accounting of the time value ensures that the entity does not recognise more expense in profit or loss than the entity actually incurs (based on the time value at inception). [IFRS 9.BC6.398]. In this scenario, over the life of the option the cumulative change in fair value of the actual time value will always be lower than the cumulative change in fair value of the aligned time value, because the actual time value was lower at inception of the hedge relationship.

IFRS 9 does not define the 'aligned time value' in much detail but it is clear that it is a key part of the concept of 'costs of hedging'. However, guidance is provided such that an entity determines the aligned time value using the valuation of the option that would have critical terms that perfectly match the hedged item. The nominal amount, life and underlying of the option are mentioned as examples of critical terms that would be expected to be matched if the option was fully aligned with the hedged item. However, this is not an exhaustive list and in the case of a hedge of one sided risk, in order to determine how much of the option premium relates to the hedged item, it is also necessary for the aligned option to represent the one sided hedged risk, even though it does not appear within the hedged item (see section 2.1 above). This is achieved by setting a strike price within the aligned option such that the intrinsic value is zero at inception of the hedge. The same issue arises in the determination of a hypothetical derivative for a one sided risk (see Illustration 7-14 in section 7.4.4 above). Accordingly, in Illustration 7-14 the strike price in the aligned derivative for Scenario 3 would be restricted to the prevailing market price of the underlying commodity at the date of designation. [IFRS 9.B6.5.32].

Although the aligned instrument is derived from the critical terms of the hedged item, this should be understood to be the designated components of the hedged item (see section 2.1 above). For example, if the hedged item was designated only for a partial term, then the aligned instrument would reflect that partial term, rather than the full life of the hedged item (see section 2.2.4 above). [IFRS 9.B6.3.11]. Further, it makes sense that regular pricing features are part of the aligned time value of an option, reflecting that they are part of the fair value of the financial instrument whose intrinsic value is designated as the hedging instrument. This is different from using a hypothetical derivative, which has the purpose of measuring the hedged item. For that purpose, features that are only in the hedging instrument but not the hedged item cannot be taken into account. This rationale does not apply for the purpose of accounting for the costs of hedging. This becomes clearer from the example of the foreign currency basis spread (see section 7.5.3 below); it cannot be included as part of a hypothetical derivative to measure the hedged item, but it is a cost of hedging.

However, similar to the need to update a hypothetical derivative to reflect changes in the timing of a forecast hedged item (see section 7.4.4 above), if expectations of the forecast transaction are revised, the terms of the 'aligned' instrument will need to be updated to reflect the change in timing. The updated aligned instrument must match all of the critical terms of the forecast transaction, as if the amended terms were known at inception of the hedge. A true up to the costs of hedging reserve and associated profit or loss for the cumulative effect of the revised aligned time value will be required.

7.5.2 Forward element of forward contracts

Entities using forward contracts in hedging relationships can designate the instrument in their entirety or exclude the forward element by designating the spot element only. The forward element is the difference between the spot and forward prices of currency forward contracts and cross currency interest rate swaps, representing the differential between the interest rates of the two currencies involved. When only the spot element is designated, an entity has a choice to apply costs of hedging accounting to the excluded forward element. This is, however, not an accounting policy choice, but an election for each designation. [IFRS 9.6.5.16]. If the costs of hedging guidance is not applied, designating the spot element of a forward contract results in the forward points (often also called the 'forward element') being accounted for at fair value through profit or loss (see section 3.6.5 above).

When designating the entire hedging instrument, it is usually desirable for the hedged item also to be measured at the forward rate instead of the spot rate in order to enhance effectiveness. For example, when hedging a highly probable forecast transaction, the hedged item, once transacted, could be measured with respect to the forward rate if the 'forward rate method' is designated (see section 7.4.7 above). However, the forward rate method does not provide a similar solution for hedges of foreign currency monetary items because of the IAS 21 requirement for such assets and liabilities to be measured at the spot rate. [IFRS 9.BC6.422]. See Illustration 7-17 in section 7.4.7 above for examples of how hedge accounting can differ when designating the spot or forward rate and on the application of the costs of hedging guidance.

When designating the spot element and applying the costs of hedging to the forward element, the change in fair value of the forward element is recognised in OCI and accumulated in a separate component of equity. The accounting for the forward element that exists at inception also follows the distinction between transaction related hedged items and time-period related hedged items that is made when accounting for the time value of an option (see in section 7.5.1 above). This means, in the case of a transaction related hedged item, that the change in the fair value of the forward element is deferred in OCI and included, like transaction costs, in the measurement of the hedged item (or it is reclassified to profit or loss when a hedged sale occurs). In case of a time-period related hedged item, the forward element that exists at inception is amortised from the separate component of equity to profit or loss on a systematic and rational basis. For example, if commodity inventory is hedged against changes in fair value for six months using a commodity forward contract with a corresponding life, the forward element of the forward contract would be allocated to profit or loss on a systematic and rational basis over that six month period. [IFRS 9.6.5.16, IFRS 9.B6.5.34, IFRS 9.B6.5.35, IFRS 9.B6.5.36].

As a result of the above accounting, fluctuations in the fair value of the forward element over time will affect OCI, and the amount accumulated in OCI will be recognised in profit or loss when the hedged item affects profit or loss (in the case of a transaction related hedged item), or be amortised to profit or loss (in the case of a time-period related hedged item). The following Illustration is designed to demonstrate the accounting for the forward element of a hedging derivative, as a cost of hedging. The fact pattern is intentionally simplified in order to isolate the costs of hedging accounting.

Illustration 7-24: Funding swaps - designating the spot risk only and using costs of hedging accounting

A bank, having the Singapore Dollar (SGD) as its functional currency, borrows money by entering into a two-year zero coupon loan denominated in Japanese Yen (JPY). The loan is accounted for at amortised cost. The bank transfers the JPY funds into its functional currency and lends the money as a SGD denominated two-year zero coupon loan. To hedge the SGD/JPY exchange risk, the bank enters into a foreign currency forward contract to buy JPY against SGD in two years' time and designates it as a hedge of the spot JPY foreign currency risk. The fair value of the forward element at inception is SGD 20,000 and it is SGD 13,000 at the end of the first year and zero at maturity.

From an economic standpoint, the bank has now hedged the foreign currency risk and locked in the interest margin for the entire two-year period.

In economic theory, the forward points represent the difference in interest rates between the two currencies involved. Hence, the forward element that exists at inception is seen as one element of the interest margin, although other elements also exist (see section 7.5.3 below).

Applying the accounting for costs of hedging to the forward element of the forward contract results in the following movement within other comprehensive income (OCI):

(All amounts in SGD thousands)	Year 1	Year 2
Reserve in equity at beginning of year	-	3
Change in fair value of forward element	(7)	(13)
Amortisation of forward element at inception	10	10
Reserve in equity at end of year	3	-
Effect on OCI for the year	3	(3)
Effect on profit or loss for the year	(10)	(10)

The bank could present the amortisation of the forward element in the income statement as part of interest expense from the borrowing, so that when considered together with the interest income from the loan, the reported interest margin reflects the combined transaction, economically fixed in SGD (see Chapter 50).

The forward element costs of hedging treatment is not solely applicable for simple foreign currency forward contracts, but applies equally to forward contracts with respect to other risks, such as commodity or interest rate. [IFRS 9.BC6.416]. We would also expect the treatment to apply to a fixed-for-fixed currency swap as arguably that is no more than a series of forward contracts applying a blended rate. However, if the hedging instrument was a currency swap with two floating-rate legs which did not have the effect of locking in a net interest margin in combination with the hedged item (e.g., in the hedge of a net investment (see section 7.3.4 above)), there is no eligible forward element to apply the costs of hedging guidance to. [IFRS 9.BC6.423, IFRS 9.BC6.424]. In addition, foreign currency contracts, such as forward contracts or currency swaps, usually attract foreign currency basis spreads, this too can be excluded from the hedge relationship and treated as a cost of hedging (see section 7.5.3 below).

Just like the accounting for the time value of an option, the accounting for the forward element as a cost of hedging applies only to the extent of the so-called 'aligned' forward element (i.e., only to the extent that the forward element relates to the hedged item - see section 7.5.1.A above). [IFRS 9.B6.5.37].

How we see it

Although not explicitly mentioned in the guidance, we believe that the aligned forward element must be based on prevailing forward rates on designation, as otherwise the aligned forward element would include costs that do not relate to the hedged risk. This means that if an existing forward contract with a non-zero fair value is designated as hedging a hedged item for which the notional, residual life, and underlying all match the forward contract, it cannot be assumed that the forward element of the off-market hedging forward contract will be the same as the aligned forward contract.

Further, it is acceptable for the type of aligned instrument to match that of the actual instrument where that makes sense, for example if a fixed-for-fixed cross-currency swap is the hedging instrument it is likely to be acceptable for the aligned instrument also to be a fixed-for-fixed cross-currency swap, rather than a series of individual aligned forward contracts. The critical terms of the aligned fixed-for-fixed cross-currency swap would however still be driven by the critical terms of the hedged item, such as nominal amount, life and underlying, rather than assume they are necessarily the same as the actual hedging swap (see section 7.5.1.A above). [IFRS 9.B6.5.37].

The above discussion focuses on the costs of hedging accounting where the forward element is excluded from the hedging instrument. It should be noted that most foreign currency instruments also include foreign currency basis spreads which can also be excluded from hedging instruments (see section 7.5.3 below).

7.5.2.A Forward element of forward contracts in a net investment hedge

It is possible to designate the forward rate as the hedged risk in a net investment hedge (see sections 7.3.3 and 7.3.4 above), but for some entities it might be preferable to designate only the spot rate, so a question arises as to the accounting treatment of the excluded forward element in a net investment hedge. The costs of hedging guidance (see section 7.5 above) is not specific to a particular type of hedge relationship, accordingly it can be applied to fair value, cash flow and net investment hedges (see section 5 above). In fact, the application guidance to IFRS 9, includes a net investment hedge as an example of a fact pattern for which the costs of hedging accounting could be applied. The example given is of a time-related hedge: a net investment that is hedged for 18 months using a foreign-exchange option, which would result in allocating the time value of the option to profit or loss over that 18-month period. [IFRS 9.B6.5.29(b)]. This guidance also confirms that for the purposes of accounting for the costs of hedging, a hedge of a net investment would ordinarily be treated as a time-period related hedge, in particular as in most cases there is no expectation of a hedged transaction (see section 7.5.1 above).

The application of the costs of hedging guidance to the excluded forward element of a forward contract is not an accounting policy choice, but an election for each designation. [IFRS 9.6.5.16]. If the costs of hedging guidance is not applied, designating the spot element of a forward contract in a net investment hedge results in the forward element being accounted for at fair value through profit or loss (see sections 3.6.5 and 7.3.4 above).

The costs of hedging accounting can only be applied to the extent that it relates to the hedged item, this is achieved by comparison with an 'aligned hedging instrument' (see section 7.5.1.A above). [IFRS 9.6.5.15]. The aligned hedging instrument must match the critical terms of the hedged item. [IFRS 9.B6.5.37]. Where the hedged item is a financial instrument or a forecast transaction for which specific terms exist, determining the aligned hedging instrument is relatively straight forward. However, given that a net investment hedge is largely an accounting concept, identifying appropriate terms for an aligned hedging instrument is more difficult. This issue also arises when determining a hypothetical derivative in a net investment hedge using a derivative (see section 7.3.3.B above).

Given that it is possible to designate the forward rate as the hedged risk in a net investment hedge and assess effectiveness using a hypothetical forward contract (see section 7.3.3.A above), it is relatively easy to conclude that an aligned hedging instrument for a net investment hedge could similarly be a simple forward. As a fixed-for-fixed cross-currency swap is generally considered to be a series of forwards, it would therefore also seem logical that a fixed-for-fixed cross-currency swap would be an acceptable aligned instrument, if consistent with the designation of the hedge relationship (see section 7.3.3.B above). There are various choices on designation that will influence the form taken by the aligned instrument in the hedge of a net investment using a derivative (see section 7.3.4 above).

Although the above analysis focuses on accounting for any excluded forward element in a net investment hedge, it is also relevant to foreign currency basis spreads (see section 7.5.3 below).

7.5.3 Foreign currency basis spreads in financial instruments

The foreign currency basis spread, a phenomenon that became very significant during the financial crisis, is a charge embedded in financial instruments that compensates for aspects such as country and liquidity risk as well as demand and supply factors. This charge only applies to transactions involving the exchange of foreign currencies at a future point in time (as, for example, in currency forward contracts or cross-currency interest rate swaps (CCIRS)).

Historically, the difference between the spot and forward prices of currency forward contracts and CCIRS only represented the differential between the interest rates of the two currencies involved, referred to as the forward element of forward contracts (see section 7.5.2 above). However, basis spreads increased significantly during the financial crisis and during the subsequent sovereign debt crisis and have become a significant and volatile component of the pricing of longer term forward contracts and CCIRS.

The standard cites currency basis spread as an example of an element that is only present in the hedging instrument, but not in a hedged item that is a single currency instrument. Consequently, this would result in some ineffectiveness even when using a hypothetical derivative for measuring ineffectiveness (see section 7.4.8 above). [IFRS 9.B6.5.5].

When using a foreign currency forward contract or a CCIRS in a hedge, the foreign currency basis spread is an unavoidable 'cost' of the hedging instrument. Hence IFRS 9 permits the accounting for foreign currency basis spreads as a 'cost of hedging', similar to the time value of options and the forward element of forward contracts.²⁹ This means that, when designating a hedging instrument, an entity can exclude the foreign currency basis spread and account for it separately as a cost of hedging, in the same way as the accounting for time value of options or the forward element of forward contracts, as described in sections 7.5.1 and 7.5.2 above. [IFRS 9.6.5.16, IFRS 9.B6.5.39].

The costs of hedging accounting treatment only applies to the extent the excluded time value of options, the forward element of forward contracts or foreign currency basis spread relates to the hedged item. IFRS 9 introduced the concept of an aligned instrument in order to calculate the extent to which the excluded portion relates to the hedged item (see section 7.5.1.A above). Similar to the requirements for determining a hypothetical derivative (see section 7.4.4 above), the aligned instrument must be based on the critical terms of the hedged item. However, an important distinction is that the aligned instrument will also include regular pricing features that would ordinarily be included in the perfect hedging instrument, e.g., foreign currency basis spreads. [IFRS 9.B6.5.32].

How we see it

In a hedge of a net investment for which the hedged item has no cash flows on which the aligned foreign currency basis instrument can be based, we believe the critical term is the designated amount of foreign currency net investment. When constructing the aligned foreign currency instrument on designation of the hedge, other pricing features that relate to foreign currency basis and the risk management objective for the hedge relationship will necessarily have to be determined based on available hedging instruments at the time of designation. See Illustration 7-25 below for an example of how this might be applied.

Illustration 7-25: Hedge of a net investment with a floating-floating cross-currency swap, using costs of hedging accounting

Entity B, with a USD functional currency, has a GBP100m net investment in wholly owned Subsidiary X. B wishes to hedge the foreign currency translation risk from the GBP net investment in X and so transacts a 5 year cross-currency swap with a GBP pay leg and USD receive leg, both attracting a floating-rate of interest. The GBP notional of the swap is GBP100M. The swap is transacted at prevailing market rates and so initially has a zero fair value.

B designates the swap as the hedging instrument in a hedge of the spot foreign currency risk in a net investment hedge of the GBP100m net investment in X. B chooses to apply the costs of hedging accounting to the excluded foreign currency basis spreads.

The aligned instrument would also be a 5 year floating-floating cross-currency swap constructed of a GBP pay leg with a notional of GBP100m, and an equivalent USD receive leg based on prevailing market rates. The aligned instrument initially also has a zero fair value.

The aligned instrument therefore reflects the critical terms of the hedged item (i.e., the designated GBP100m net investment), the risk management objective (i.e., 5 year maturity) and the pricing feature with respect to foreign currency basis transacted (i.e., two floating legs). This aligned instrument can then be used to calculate the amount to be accumulated in a separate component of equity representing the cost of hedging related to foreign currency basis spread (see Illustration 7-26 in section 7.5.3.A below).

In this example the aligned instrument is the same as the actual hedging instrument, but this will not always be the case, in particular if using a hedging instrument with a non-zero fair value on designation.

Further, it is important to note that the aligned instrument in this example is constructed to reflect only the cost of hedging with respect to foreign currency basis. It would not be appropriate to apply the cost of hedging to the forward rate as well in this fact pattern, as the two floating-rate legs of the hedging instrument do not have the effect of locking in an interest differential. In that case there is no eligible forward element to apply the costs of hedging guidance to (see section 7.5.2 above). [IFRS 9.BC6.423, IFRS 9.BC6.424].

29 [IASB Update](#), January 2013, available on the IFRS Foundation's website.

Consistent with the approach to designation of the forward element as a cost of hedging, designation of foreign currency basis as a cost of hedging is not an accounting policy choice, but an election for each designation. However, if an entity designates the entire hedging instrument, fair value changes due to changes in the foreign currency basis spread would result in some ineffectiveness (see section 7.4.8 above).

It might be the case for some hedging instruments that contain both a forward element and foreign currency basis that it is more operationally efficient to designate only the spot risk and calculate the combined cost of hedging, rather than the forward element and foreign currency basis individually, or designating the forward rate and excluding only the foreign currency basis spread. Where the combined cost of hedging is selected, and only where no other sources of ineffectiveness arise, the combined cost of hedging for both a forward element and foreign currency basis could be determined as the residual fair value change after the relevant value change due to spot risk has been calculated (see section 7.3.4 and Illustrations 7-17 and 7-18 in section 7.4.7 above). The standard does not explicitly permit a combined treatment, but for many scenarios the aggregate of the individual costs of hedging accounting will equate to the costs of hedging accounting calculated on a combined basis.

7.5.3.A Measurement of the costs of hedging for foreign currency basis spread

Although the standard is clear that the costs of hedging accounting method can be applied to the foreign currency basis spread within hedging instruments, it is less clear as to how to identify the foreign currency basis spread for this purpose. We outline below two possible approaches for the identification of the foreign currency basis spread; other acceptable approaches could exist:

Approach 1: Based on the difference between the fair value of the actual foreign currency hedging instrument and the value of a hypothetical instrument derived and valued using market data excluding foreign currency basis spread. In this approach, the hypothetical instrument does not include any basis spread adjustment and has a fair value of zero based on market curves, excluding foreign currency basis spread.

Approach 2: Based on the difference between the fair value of the actual foreign currency hedging instrument and its value calculated using market data excluding foreign currency basis spread. In this approach, the hypothetical instrument includes a basis spread adjustment and has a non-zero fair value based on market curves, excluding foreign currency basis spread. This value at inception must be amortised from other comprehensive income into profit or loss on a systematic and rational basis.

Illustration 7-26: Calculation of the value of foreign currency basis spread

Entity A has functional currency of GBP and issued three year USD100m fixed rate debt on 31/12/X0, paying a semi-annual coupon of 3.75%. In order to eliminate variability in the fair value of the debt with respect to interest rate and foreign currency risk, Entity A transacted a foreign currency swap (Swap A) on the same day as follows:

Pay leg - GBP64.2m paying 6m benchmark interest rate +2.757% (semi-annual) maturing on 31/12/X3

Receive leg - USD100m paying 3.75% (semi-annual) maturing on 31/12/X3

The spread of 2.757% on the GBP floating leg includes an amount of -0.103% that represents the foreign currency basis spread priced into the swap contract. (Quoted prices for foreign currency basis spreads for many currency pairs are widely available).

Entity A designates the debt and Swap A in a fair value hedge of foreign currency and interest rate risk, and wishes to apply the costs of hedging approach to the foreign currency basis spread. The hedge is a time-period related hedge (see section 7.5.1 above).

The receive leg of Swap A matches the cash flows from the debt exactly. As the critical terms of the foreign currency basis swap are aligned with the hedged debt, there is no need to create an aligned foreign currency basis swap (see section 7.5.1.A above). For the purposes of this example no other valuation sources of ineffectiveness arise, although this is unlikely to be the case in practice.

Below are two possible approaches to calculating the value of the foreign currency basis spread to be recognised in other comprehensive income as part of the costs of hedging:

Approach 1 - Swap B

Entity A creates hypothetical Swap B. The receive leg of Swap B will exactly match the receive leg of Swap A (which also matches the debt). The pay leg of Swap B must be derived to achieve an overall zero fair value for Swap B on designation, based on market curves, excluding foreign currency basis spread. Accordingly, Swap B might look like the following:

Pay leg - GBP64.2m paying 6m benchmark interest rate +2.86% (semi-annual) maturing on 31/12/X3

Receive leg - USD100m paying 3.75% (semi-annual) maturing on 31/12/X3

(The spread of 2.86% on the GBP floating leg does not include an amount representing foreign currency basis spread).

The accounting for the hedge relationship would be as follows:

Instrument	Fair value on designation	Accounting
Debt	Nil	Value changes due to foreign currency and interest rate risk (using discount curves that do not reflect foreign currency basis spread) are recognised in profit or loss, and adjust the carrying value of the debt. (The recognised changes in value of the debt will be offset by changes in the fair value of Swap B's receive leg).
Swap B (hypothetical swap)	Nil	Changes in fair value due to foreign currency and interest rate risk (using discount curves that do not reflect foreign currency basis spread) are recognised in profit or loss.
Swap A (actual swap)	Nil	Changes in fair value of Swap A (i.e., using discount curves that reflect foreign currency basis spreads) LESS the calculated changes in the fair value of Swap B, are recognised in other comprehensive income as the costs of hedging. In the statement of financial position, Swap A is recognised at its fair value at all times.
Other comprehensive income		As the fair value of the foreign currency basis spread is zero at inception, there is no requirement for a systematic and rational amortisation of the costs of hedging from other comprehensive income into profit or loss. [IFRS 9.6.5.15(c)]. The value of the foreign currency basis spreads at inception (nil) equals the initial fair value of Swap A (nil) less the initial fair value of Swap B (nil).

Approach 2 - Swap C

Entity A creates hypothetical Swap C. The terms of Swap C exactly match the terms of Swap A, but Swap C would be fair valued based on market curves excluding foreign currency basis spread. (It should be noted that the receive leg of Swap C in this example also matches the debt). Swap C will have a fair value on designation which is equal to the net present value of the foreign currency basis spread included within the GBP pay leg (e.g., a negative spread of 0.103% in this example). Accordingly Swap C will look like the following:

Pay leg - GBP64.2m paying 6m benchmark interest rate +2.757% (semi-annual) maturing on 31/12/X3.

Receive leg - USD100m paying 3.75% (semi-annual) maturing on 31/12/X3

The fair value of Swap C on designation is an asset of £132k, this is calculated using market curves excluding foreign currency basis spread.

The accounting for the hedge relationship would be as follows:

Instrument	Fair value on designation	Accounting
Debt	Nil	Value changes due to foreign currency and interest rate risk (using discount curves that do not reflect foreign currency basis spread) are recognised in profit or loss, and adjust the carrying value of the debt. (The recognised changes in value of the debt will be offset by changes in the fair value of Swap C's receive leg).
Swap C (hypothetical swap)	£132k DR	Changes in fair value due to foreign currency and interest rate risk (using discount curves that do not reflect foreign currency basis spread) are recognised in profit or loss.
Swap A (actual swap)	Nil	Changes in fair value of Swap A (i.e., using discount curves that reflect foreign currency basis spreads) LESS the calculated changes in the fair value of Swap C, are recognised in other comprehensive income as the costs of hedging. In the statement of financial position, Swap A is recognised at its fair value at all times.

Other
comprehensive
income

The value of the foreign currency basis spread at inception must be amortised from other comprehensive income into profit or loss on a systematic and rational basis. [IFRS 9.6.5.15(c)].

The value of the foreign currency basis spread at inception (GBP132k CR) is the initial fair value of Swap A (nil) less the initial fair value of Swap C (GBP132k DR).

Over the life of the hedge relationship the cumulative amortisation will result in the following:

DR other comprehensive income GBP132k

CR profit or loss GBP132k

The above fact pattern assumes that there are no sources of ineffectiveness and that the hedging derivative exactly matches the critical terms of the hedged item. In reality this is unlikely to always be the case, therefore additional complexity might need to be incorporated into the chosen approach for identifying the foreign currency basis spread. In particular, where the critical terms of the hedging derivative do not match those of the hedged item, it is the aligned foreign currency basis spread which is eligible for the costs of hedging treatment (see section 7.5.1.A above). In that case swap B and C (above) must be based on an aligned foreign currency derivative, i.e., one that would perfectly match the hedged item. Differences in fair value changes between the actual foreign currency derivative and the aligned foreign currency derivative will be an additional source of ineffectiveness (see section 7.5.2 above).

[IFRS 9.B6.5.37, IFRS 9.B6.5.38].

Although quoted prices for foreign currency basis spreads for many currency pairs are widely available, entities must not underestimate the complexities involved in eliminating the effect of foreign currency basis spreads from market forward foreign currency rates which generally do reflect foreign currency basis spreads.

7.6 Hedges of a firm commitment to acquire a business

A firm commitment to acquire a business in a business combination cannot be a hedged item, except for foreign currency risk (see section 2.6.4 above).

Consider the situation where an entity with euro as its functional currency enters into a binding agreement to purchase a subsidiary in six months. The subsidiary's functional currency is the US dollar. The consideration is denominated in US dollars and is payable in cash. The entity decides to enter into a forward contract to buy US dollars for euros to hedge its foreign currency risk on the firm commitment. The following options exist and the entity could choose the most appropriate accounting treatment:

- Because the hedge is a purchase of US dollars, it is, arguably, not a fair value hedge of the acquisition, since the acquisition is itself naturally hedged for changes in the fair value in the US dollar - that is, the entity is committed to buy a group of US dollar denominated assets and liabilities for a price denominated in US dollars. Nevertheless, the entity could still designate the transaction as the hedged item in a fair value hedge relationship, although this might not make intuitive sense (see section 5.1.1 above). [IFRS 9.B6.5.3].
- The entity could instead designate the forward contract as a hedge of the cash flows associated with the committed purchase, which is a cash flow hedge (see section 5.2.2 above). [IFRS 9.B6.3.1].

Or

- If the anticipated business combination in this example is only a highly probable forecast transaction and not a firm commitment, then the entity can only apply cash flow hedging (see section 2.6.1 above).

If the transaction is a fair value hedge, then the carrying amount of the hedged item is adjusted for the gain or loss attributable to the hedged risk (see section 7.1 above). Since separately identifiable assets acquired and liabilities assumed must be recognised on initial consolidation at fair value in the consolidated financial statements of the acquirer, it follows that the gain or loss attributable to the hedged risk must be included in the consideration paid. In other words, the impact of the hedge affects the calculation of goodwill that is otherwise determined by the application of IFRS 3 (see Chapter 10).³⁰

During the hedging period, the effective portion of the gain or loss on a hedging instrument in a cash flow hedge is recognised in other comprehensive income (see section 7.2 above). Upon initial recognition of the acquisition, gains or losses recognised in other comprehensive income are included in the consideration paid for the business combination that is designated as the hedged item. [IFRS 9.6.5.11(d)(i)]. A similar treatment would be applied to any amounts in a separate component of equity relating to the costs of hedging (see section 7.5.1 above).

30 [IFRIC Update](#), January 2011, available on the IFRS Foundation's website.

The adjusted carrying amount of goodwill, including the gain or loss from hedge accounting, will then be subject to the normal requirements to test for annual impairment (see Chapter 21).

Once the purchase price is paid and the transaction is completed, the entity is 'long' US dollars as a result of recognising the US dollar net assets of the acquired entity. Those net assets would then be eligible for net investment hedging which would require selling US dollars to create an eligible hedging instrument, for example by entering into a foreign currency forward (see sections 5.3 and 7.3 above).

7.7 Hedge accounting for a documented replacement or rollover hedging strategy

The standard is clear that the replacement or rollover of a hedging instrument into another hedging instrument is not an expiration or termination of a hedge relationship if such replacement or rollover is part of the entity's documented risk management objective (see section 8.3 below). [IFRS 9.6.5.6]. However, there is minimal additional specific guidance provided on what is meant by, or the accounting for, a documented replacement or rollover hedging strategy.

How we see it

We believe that a rollover hedging strategy refers to a strategy whereby the maturity of the hedging instrument is intentionally shorter than the maturity of the hedged item, and there is an expectation that on expiry of the original hedging instrument it will be replaced by a new hedging instrument. The replacement hedging instrument is likely to have similar characteristics to the instrument being replaced.

A replacement hedging strategy is also not defined but is likely to include a strategy to replace hedging instruments if the credit risk from the existing instrument increases such that it exceeds acceptable levels. Whether the risk management strategy is to be achieved through a replacement or rollover strategy is a matter of fact, and must have been documented as such at inception of the initial hedge and the usual qualifying conditions for hedge accounting must be met (see section 6 above).

An entity's risk management strategy is the main source of information to perform an assessment of whether a hedging relationship meets the effectiveness requirements, for example whether an economic relationship exists between the hedged item and the hedging instrument. [IFRS 9.B6.4.18]. Therefore, when making this assessment for a rollover hedging strategy, it will be necessary to consider whether the risk management strategy does envisage rolling over the hedging instrument (see section 6.4.1 above and Illustration 7-27 below). [IFRS 9.B6.4.6].

The measurement of hedge ineffectiveness is undertaken on a cumulative basis (see sections 7.1.1 and 7.2.1 above). [IFRS 9.6.5.8, IFRS 9.6.5.11]. 'Cumulative' is generally understood to mean over the life of the hedge relationship. This will include historic gains and losses from previous periods in which the hedging instruments were rolled over or replaced, for as long as the hedge continues to remain live. The cumulative period is not reset just because a new replacement or rollover hedging instrument is transacted if it is part of a documented replacement or rollover strategy, as it is not an event that requires discontinuation of the hedge relationship. This is particularly relevant for a cash flow hedge in the identification of the hypothetical derivative, as demonstrated in Illustration 7-27 below (see also section 7.4.4 above).

Illustration 7-27: Hedge of a foreign currency risk in rollover cash flow hedging strategy

Company A has sterling as its functional currency. Company A expects highly probable foreign currency sales resulting in a forecast cash inflow of €2m in 9 months' time. Company A chooses to hedge the foreign currency risk and transacts an FX forward contract to sell €2m and receive GBP in 3 months' time. This is with an expectation that as the initial contract matures another 3-month contract will be transacted and then a third contract on maturity of the second contract. As part of the usual hedge documentation Company A has identified this as being a rollover strategy for foreign currency risk. Company A has determined that the effectiveness criteria are met on initial designation, this was on the assumption that the existing 3-month hedging contract will be rolled into a second and third 3-month hedging contract (see section 6.4 above).

The hedge relationship is not discontinued when the second and third FX forward contracts are transacted. The effectiveness requirements are assessed throughout the life of the hedge relationship, including consideration of the expected rollover of the hedging instruments (see section 6.4 above). The amount of ineffectiveness recorded is determined by a comparison of the change in fair value of the hedging instruments (the aggregate of the changes in fair value of the 3-month FX forward contracts) and the change in value of the hedged item (the highly probable cash flow in 9 months' time) for changes in foreign currency risk. This cumulative approach means the calculation would include fair value changes since designation of the hedge relationship, which would include the realised changes in fair value of the matured 3-month FX forward contracts.

If the hypothetical derivative method (see section 7.4.4 above) is adopted to calculate the change in value of the hedged item, a single hypothetical derivative would be used based on the expected timing of the forecast transaction (i.e., a 9-month FX forward contract).

It follows that if the costs of hedging guidance is applied to a hedge relationship with a documented replacement or rollover strategy then a replacement of the hedging instrument will not be deemed a discontinuation for the purposes of accounting for the costs of hedging either. This is particularly important for a time related hedge for which the amount accumulated in the separate component of equity is immediately reclassified to profit or loss when the hedge relationship is discontinued (see section 7.5.1 above).

An alternative risk management objective to a rollover strategy would be a partial term hedge, i.e., when the entity chooses to manage the hedged risk for only a partial term, perhaps because there is an expectation that a natural hedge will occur at some point in the future (see section 2.2.4 above). In that case there is no expectation that on expiry of the original hedging instrument it will be replaced by a new hedging instrument with similar characteristics to the instrument being replaced, hence it is not the same as a rollover strategy.

Accordingly, the documented risk management objective for such a hedge relationship (see section 6.2 above) will highlight if it is either a rollover strategy or a partial term hedge, and the assessment of the effectiveness requirements (see section 6.4 above) and measurement of ineffectiveness (see section 7.4 above) will be assessed on that basis.

Amortisation of any fair value adjustment made to the hedged item under a fair value hedge of a documented rollover strategy need not commence until the rollover hedge strategy is discontinued (see section 7.1.2 above).

7.8 Hedge accounting for an equity instrument designated at fair value through OCI

It is clear from the standard that it is possible to designate as the hedged item in a fair value hedge, an investment in an equity instrument for which the entity has elected on initial recognition to present changes in fair value in OCI (see section 2.6.3 above). [IFRS 9.6.5.3]. Applying that initial recognition election, with the exception of dividends received, means that subsequent gains or losses on the equity investments will never be recognised in profit or loss, (see Chapter 46). However, for such a hedge, all fair value changes of the hedging instrument are recognised in OCI. [IFRS 9.6.5.8].

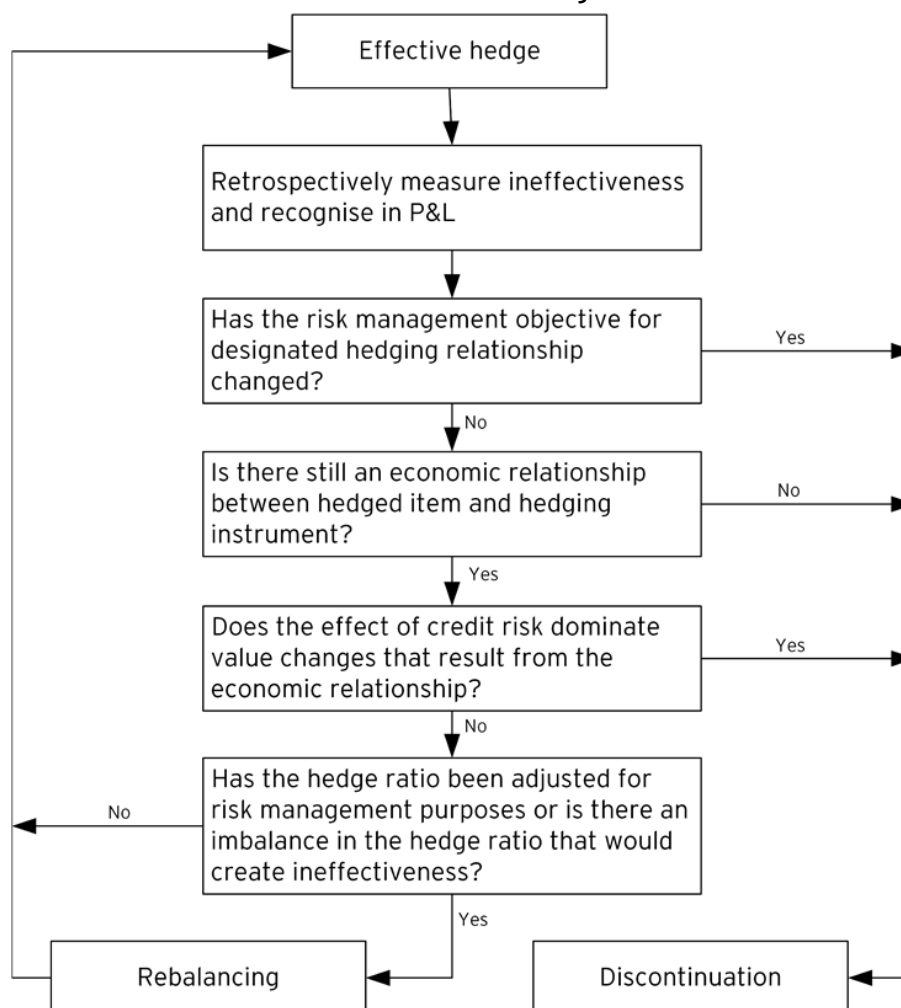

This treatment can lead to an accounting mismatch as value changes for the hedged item when a dividend is recognised will be reflected in profit or loss but remain in OCI for the hedging instrument.

8 Subsequent assessment of effectiveness, rebalancing and discontinuation

8.1 Assessment of effectiveness

A prospective effectiveness assessment is required on an ongoing basis, in a similar manner as at the inception of the hedging relationship (see section 6 above) and, as a minimum, at each reporting date or upon a significant change in circumstances, whichever comes first, in order to continue to apply hedge accounting. [IFRS 9.B6.4.12]. The flow chart below illustrates the assessment life cycle.

Figure 8-1: Effectiveness assessment and rebalancing

Each accounting period an entity first must assess whether the risk management objective for the hedging relationship has changed. A change in risk management objective is a matter of fact that triggers discontinuation prospectively. Discontinuation of hedging relationships is discussed in section 8.3 below.

An entity would also have to discontinue hedge accounting prospectively if it turns out that there is no longer an economic relationship (see section 6.4.1 above). This makes sense as whether there is an economic relationship is a matter of fact that cannot be altered by adjusting the hedge ratio (see section 6.4.3 above). The same is true for the impact of credit risk; if credit risk is now dominating the hedging relationship, then the entity must discontinue hedge accounting prospectively (see section 6.4.2 above). [IFRS 9.6.5.6].

The hedge ratio might need to be adjusted if it turns out that the hedged item and hedging instrument do not move in relation to each other as expected, or if the ratio has changed for risk management purposes. This is referred to as 'rebalancing' and is discussed in section 8.2 below.

It can be seen from the above flow chart that hedge accounting can only continue prospectively if the risk management objective has not changed, and the effectiveness requirements continue to be met. Otherwise the hedge relationship must be discontinued (see section 8.3 below).

8.2 Rebalancing

8.2.1 Definition

Extract from IFRS 9

6.5.5 If a hedging relationship ceases to meet the hedge effectiveness requirement relating to the hedge ratio (see paragraph 6.4.1(c)(iii)) but the risk management objective for that designated hedging relationship remains the same, an entity shall adjust the hedge ratio of the hedging relationship so that it meets the qualifying criteria again (this is referred to in this Standard as 'rebalancing'—see paragraphs B6.5.7–B6.5.21).

[IFRS 9.6.5.5].

An entity is required to 'rebalance' the hedge ratio to reflect a change in the relationship between the hedged item and hedging instrument if it expects the new relationship to continue going forward.

Extract from IFRS 9

B6.5.7 Rebalancing refers to the adjustments made to the designated quantities of the hedged item or the hedging instrument of an already existing hedging relationship for the purpose of maintaining a hedge ratio that complies with the hedge effectiveness requirements. Changes to designated quantities of a hedged item or of a hedging instrument for a different purpose do not constitute rebalancing for the purpose of this Standard.

[IFRS 9.B6.5.7].

Rebalancing allows entities to refine their hedge ratio without discontinuation and redesignation, so reducing the need for designation of 'late hedges' and the associated accounting issues that can arise with such a hedge (see sections 2.4.1 and 7.4.3 above). [IFRS 9.B6.5.7]. Specifically, if entities change the quantity of hedged item compared to the quantity of hedging instrument in response to changes in the economic relationship between the hedged item and hedging instrument, when the risk management objective otherwise continues as originally designated that should be treated as a continuation of the hedging relationship. [IFRS 9.BC6.303].

For instance, an entity could have designated a hedging relationship in which the hedging instrument and the hedged item have different but related underlying reference indices, rates or prices. If the relationship or correlation between those two underlyings change, the hedge ratio might need to change to better reflect the revised correlation and to continue to comply with the hedge effectiveness requirements.

[IFRS 9.B6.5.7, IFRS 9.B6.5.9].

By way of an example; an entity hedges an exposure to Foreign Currency A using a currency derivative that references Foreign Currency B. Foreign Currency A and B are pegged (i.e., their exchange rate is maintained within a band or at an exchange rate set by a central bank or other authority). If the exchange rate between Foreign Currency A and Foreign Currency B were changed (i.e., a new band or rate was set), rebalancing the hedging ratio to reflect the new exchange rate would ensure that the hedging relationship would continue to meet the hedge effectiveness requirements. [IFRS 9.B6.5.10].

Any other changes made to the quantities of the hedged item or hedging instrument, for instance, a reduction in the quantity of the hedged item because some cash flows are no longer highly probable, would not be rebalancing. Such other changes to the designated quantities would need to be treated as a partial discontinuation if the entity reduces the extent to which it hedges, and a new designation of a hedging relationship if the entity increases it. [IFRS 9.B6.5.7].

Changes that risk managers might make to improve hedge effectiveness but which are not caused by a change in the economic relationship between the hedged item and the hedging instrument are not rebalancing either as they would reflect a change in the risk management objective. [IFRS 9.B6.5.15]. An example of such a change is the transaction of derivatives related to a risk (or source of ineffectiveness) that was not considered in the original hedge relationship or a known risk (or source of ineffectiveness) that has become larger/more volatile since inception or that the entity intended to hedge dynamically to maintain a desired level of offset (see section 6.3.2 above).

Where differences in the underlying or risk variables within the hedged item and hedging instrument exist, it is likely that there is already a degree of hedge ineffectiveness within the hedge relationship (see section 7.4 above). The concept of rebalancing only comprises prospective changes to the hedge ratio, so any ineffectiveness is determined and recognised immediately before adjusting the hedging relationship for rebalancing. [IFRS 9.B6.5.8].

For example, hedging a cotton purchase in India with NYMEX cotton futures contracts is likely to result in some ineffectiveness, as the hedged item and the hedging instrument do not share exactly the same underlying price. Rebalancing only affects the expected relative sensitivity between the hedged item and the hedging instrument going forward, as ineffectiveness from past changes in the sensitivity will have already been recognised in profit or loss.

The following Illustration provides some indications as to how to distinguish rebalancing from other changes to a hedge relationship:

Illustration 8-1: Rebalancing

Fact pattern 1

An entity is exposed to price changes in commodity A which is not widely traded as a derivative. The entity has proven that there is an economic relationship between commodity A and commodity B. Commodity B is widely traded as a derivative. In that case, the entity could use commodity B derivatives to hedge the price risk in commodity A. An initial hedge ratio of 1:1.1 is based on the expected relationship between the prices of commodity A and commodity B. The relationship subsequently changes such that a ratio of 1:1.15 is expected to be more effective.

The entity can account for the changes in the hedging relationship as rebalancing because the difference between the prices is caused by a change in the economic relationship between the hedged item and hedging instrument such that a change is required to the hedge ratio so that it complies with the hedge effectiveness requirements.

Fact pattern 2

An entity swaps a base rate floating rate loan into a fixed interest rate using a pay SONIA receive fixed swap. At inception, the entity is able to prove that there is an economic relationship between the base rate and SONIA and designates the swap and the loan in a cash flow hedge, although it expects some level of ineffectiveness (see section 6.4.1 above). Similar to fact pattern 1, the entity could use rebalancing to account for changes in the basis risk between the base rate and SONIA.

However, the entity subsequently transacts a SONIA versus base rate swap in order to eliminate the basis risk. The accounting consequences would depend on the reason for doing so and here we consider two scenarios:

- (a) The entity can no longer prove that there is an economic relationship between the base rate and SONIA (although this is unlikely in practice).
- (b) The entity can still prove that there is an economic relationship between the base rate and SONIA, but no longer wishes to suffer the resultant ineffectiveness arising from the basis risk.

In scenario a), the hedging relationship no longer meets the eligibility criteria and needs to be discontinued, as there is no longer an economic relationship between the hedged item and the hedging instrument. The entity cannot use rebalancing to avoid discontinuation because the hedge no longer meets the qualifying criteria (see section 8.3 below).

In scenario b), the entity tries to avoid ineffectiveness by contracting another hedging instrument. Arguably, the entity could continue with the original designation and account for the SONIA versus base rate swap as a derivative measured at fair value through profit or loss. However, given that the entity seeks to avoid ineffectiveness, it might want to apply hedge accounting to the base rate swap as well. If the entity wants to include the SONIA versus base rate swap in the original hedging relationship, it would represent a change in the documented risk management objective which requires discontinuation of the existing and re-designation of a new hedging relationship (see section 7.4.3 above for further discussion on designating hedging derivatives with a non-zero fair value in a hedge relationship).

Fact pattern 3

An entity with US dollars as its functional currency designated a fixed rate loan denominated in EUR and a US dollars/euro forward exchange contract in a cash flow hedge. Subsequently, the borrower suffers significant financial difficulties and the entity only expects to receive 90% of the contractual cash flows on the loan.

The entity cannot apply rebalancing because the changes in the cash flows of the hedged item are not caused by a change in the economic relationship between the underlying or risk variables within the hedged item and hedging instrument but by credit risk. Instead, the entity is required to assess whether credit risk dominates the fair value changes of the hedged item in which case the hedging relationship needs to be discontinued (see section 8.1 above). If it is determined that credit risk does not dominate the hedge relationship the entity might, adjust the amount of the hedging instrument to reflect the reduced volume of the hedged risk and treat this as a partial dedesignation (see section 8.3 below).

Fact pattern 4

An airline with a functional currency of Swiss francs enters into a firm commitment to purchase ten new wide-bodied airplanes in two years' time. The contract to purchase those airplanes is denominated in US dollars and the airline enters into a forward exchange contract to hedge the foreign currency exposure. There is no embedded foreign currency derivative to bifurcate, as sales of wide-bodied aircrafts appear to be routinely denominated in US dollars around the world (see Chapter 42). The airline designates the firm commitment and the derivative in a fair value hedge. Six months into the contract, the aircraft manufacturer informs the airline that it has suffered significant delays in production and that the aircrafts will not be delivered in two years as originally planned but in three years. Payment is due when the airplanes are delivered.

The delay in payment might result in some ineffectiveness as the forward exchange and discounting rates for two years and three years are likely to be different (see section 7.4.4 above). However, the airline could not avoid this ineffectiveness by rebalancing, because the ineffectiveness is caused by the timing difference and not a change in the economic relationship between the underlying or risk variables within the hedged item and hedging instrument. Further, were the airline to alter the quantities of the hedged item or the hedging instrument (which is what rebalancing entails), it is unlikely to resolve the ineffectiveness.

8.2.2 Requirement to rebalance

Whether an entity is required to rebalance a hedging relationship is first and foremost a matter of fact, which is, whether the hedge ratio has changed for risk management purposes. An entity must rebalance a hedging relationship if that relationship has an unchanged risk management objective but no longer meets the hedge effectiveness requirements regarding the hedge ratio (see section 6.2 and section 6.4.3 above). This will, in effect, be the case if the hedge ratio is no longer the one that is actually used for risk management (see section 6.4.3 above). [IFRS 9.6.5.5].

However, consistent with initial designation, the hedge ratio used for hedge accounting purposes might have to differ from the hedge ratio used for risk management if the latter would result in ineffectiveness that could result in an accounting outcome that would be inconsistent with the purpose of hedge accounting (see section 6.4.3 above). [IFRS 9.B6.5.14]. The guidance in IFRS 9 clarifies that an accounting outcome that would be inconsistent with the purpose of hedge accounting as the result of failing to adjust the hedge ratio for risk management purposes, would not meet the qualifying criteria for hedge accounting. This simply means that the qualifying criteria treat inappropriate hedge ratios in the same way, irrespective of whether they were achieved by acting (inappropriate designation) or failure to act (by not adjusting a designation that has become inappropriate). [IFRS 9.B6.5.13].

IFRS 9 also clarifies that not every change in the extent of offset between the hedging instrument and the hedged item constitutes a change in the relationship that requires rebalancing. For example, hedge ineffectiveness arising from a fluctuation around an otherwise valid hedge ratio cannot be reduced by adjusting the hedge ratio. [IFRS 9.B6.5.11, IFRS 9.B6.5.12]. A trend in the amount of ineffectiveness on the other hand might suggest that retaining the hedge ratio would result in increased ineffectiveness going forward.

Accordingly, in order to continue to apply hedge accounting, an entity must rebalance the hedge ratio for accounting purposes if required as part of the prospective effectiveness assessment. IFRS 9 acknowledges that such an assessment is usually inherent in effective risk management monitoring, and so in many cases existing risk management process might be sufficient to determine whether accounting rebalancing is required or not. [IFRS 9.BC6.301].

IFRS 9 does not specify the nature of the assessment to determine if rebalancing is required. Therefore, the nature of the assessment requires judgement based on the facts and circumstances of the hedge relationship. For example, a hedge involving two underlyings with correlation that has been historically volatile would likely require more robust analysis than two underlyings that have shown consistent correlation over many years. As another example, a relationship that has been under-hedging for four consecutive quarters would likely require more robust analysis than a relationship constantly moving to and from an over- and under-hedge position.

Regardless of the chosen assessment methodology, it is clear that rebalancing is not a mathematical optimization exercise. [IFRS 9.BC6.310]. Accordingly, hedges are not required to be perfectly effective, but judgement will be required to determine if rebalancing is necessary or not. Therefore, at each reporting date, entities must document the work performed to determine whether rebalancing is necessary or not, and any judgements made.

8.2.3 Mechanics of rebalancing

Extract from IFRS 9

B6.5.8 Rebalancing is accounted for as a continuation of the hedging relationship in accordance with paragraphs B6.5.9-B6.5.21. On rebalancing, the hedge ineffectiveness of the hedging relationship is determined and recognised immediately before adjusting the hedging relationship.

[IFRS 9.B6.5.8].

Once any hedge ineffectiveness has been recognised, rebalancing can be achieved by:

- Increasing the volume of the hedged item
 - Increasing the volume of the hedging instrument
 - Decreasing the volume of the hedged item
- Or
- Decreasing the volume of the hedging instrument [IFRS 9.B6.5.16]

Decreasing the volume of the hedging instrument or hedged item does not mean that the respective transactions or items no longer exist or are no longer expected to occur. As demonstrated in Illustration 8-2 and Illustration 8-3 below, rebalancing only changes what is designated in the particular hedging relationship.

Illustration 8-2: Rebalancing the hedge ratio by decreasing the volume of the hedging instrument

1 January

An entity expects to purchase 1m barrels of West Texas Intermediate (WTI) crude oil in 12 months. The entity designates a futures contract of 1.05m barrels of Brent crude oil in a cash flow hedge to hedge the highly probable forecast purchase of 1m barrels of WTI crude oil (hedge ratio of 1.05:1) in a cash flow hedge. This hedge ratio is consistent with risk management and is not designed to result in an accounting outcome that would be inconsistent with the purpose of hedge accounting.

30 June

At 30 June, the cumulative change in the value of the hedged item is CU200, while the cumulative change in the fair value of the hedging instrument is CU229.

The entity would account for the hedging relationship as follows (see section 7.2 above):

		CU	CU
Dr	Cash flow hedge reserve - OCI	200	
Dr	Hedge ineffectiveness - profit or loss	29	
	Cr Derivatives - hedging instruments		229

The treasurer of the entity is very sensitive to ineffectiveness and therefore considers rebalancing the hedging relationship.

The analysis of the treasurer shows that the sensitivity of Brent crude oil to WTI crude oil prices was not as expected. Going forward, the treasurer expects a different relationship between the two benchmark prices and decides to reset the hedge ratio to 0.98:1 accordingly.

Rebalancing on 30 June

The treasurer can either designate more WTI exposure or de-designate part of the Brent crude oil hedging instrument. The entity decides to do the latter, that is, discontinue hedge accounting for 0.07m barrels of Brent crude oil derivatives.

Of the total of 1.05m barrels of Brent derivative, 0.07m are no longer part of the hedging relationship. Therefore, the entity needs to reclassify 7/105 (or 6.7%) of the hedging instrument within their hedge accounting disclosures (see Chapter 50). No immediate accounting entries are required to reflect the rebalancing in this case.

In Illustration 8-2 above, the entity no longer needs to hold this portion of the derivative any longer for hedging purposes and could, therefore, close it out. If the entity chooses to keep that portion of the derivative it will of course continue to result in volatility in the profit or loss, although it would no longer be presented as hedge ineffectiveness. As mentioned, the entity could have also rebalanced by designating more WTI exposure (assuming that the higher level of exposure is highly probable of occurring). Such an approach would also not result in any immediate accounting entries; the entity would simply designate more WTI exposure. However, the ongoing accounting can be more complex, which is discussed in more detail below. The same would be true when rebalancing by increasing the volume of hedging instrument, in which case the entity would simply designate more of the same hedging instruments within the hedge relationship. This could be achieved either by entering into additional hedging instruments via a market transaction, or by designating existing derivatives that are not currently designated within a hedge relationship. [IFRS 9.B6.5.16, IFRS 9.B6.5.17, IFRS 9.B6.5.18, IFRS 9.B6.5.19, IFRS 9.B6.5.20].

Illustration 8-3: Rebalancing the hedge ratio by decreasing the volume of hedged item

1 April

An entity has highly probable forecast purchases of diesel over the next 12 months. The entity expects to get monthly deliveries of 10,000 metric tonnes at the local market price. The entity designates a futures contract referenced to the Platts Diesel D2 price with a nominal amount of 9,500 metric tonnes in a cash flow hedge, to hedge 10,000 metric tonnes of highly probable diesel purchases in September (giving a hedge ratio of 1:0.95).

30 June

At 30 June, the cumulative change in the value of hedged item is CU820, while the cumulative change in the fair value of hedging instrument is CU650.

The entity would account for the hedging relationship as follows:

	CU	CU
Dr Cash flow hedge reserve - OCI	650	
Cr Derivatives - hedging instruments		650

To account for the fair value change of the hedging instrument.

Despite the hedge only being 79% effective, no hedging ineffectiveness is recorded as a result of the 'lower of test' in the standard. [IFRS 9.6.5.11(a)]. As per that paragraph, the amount accumulated in other comprehensive income has to be the lower of:

- (i) The cumulative gain or loss on the hedging instrument
- And
- (ii) The cumulative change in fair value of the hedged item, with any remaining gain or loss on the hedging instrument being recorded in profit or loss (see section 7.2 above)

Based on an analysis, the entity now believes that the appropriate hedge ratio going forward is 1:1.05. Consequently, the entity can either increase the volume of hedging instrument or decrease the volume of hedged item. Based on a cost-benefit analysis the entity decides to reduce the volume of hedged item by 952 metric tonnes.

Rebalancing on 30 June

Rebalancing a hedge ratio by decreasing the volume of hedged item is considered a partial discontinuation of the hedging relationship. [IFRS 9.B6.5.27(a)]. The entity is discontinuing 952 (10,000 - (9,500 ÷ 1.05) = 952) metric tonnes of diesel purchases while 9,048 metric tonnes of forecast purchases remain in the hedging relationship. The hedge documentation is updated accordingly. No accounting entry is required (however, the entity would have to retain the information that 952 metric tonnes of diesel were the hedged item for some part of the total life of the hedging relationship and which amount in the cash flow hedge reserve relates to this quantity of diesel).

Even though the standard allows adjusting either the quantity of hedging instrument or the quantity of the hedged item, when rebalancing, entities are encouraged to consider that adjusting the hedged item will be operationally more complex than adjusting the hedging instrument because of the need to track the history of different quantities that were designated during the term of the hedging relationship. For example, if a quantity of 10 tonnes of a hedged item were added to increase the quantity of hedged item and later deducted to decrease it, those 10 tonnes would have been part of the hedged item for only a part of the life of the hedging relationship. However, the amount accumulated in the cash flow hedge reserve, would still, in part, relate to that quantity, even though it is not currently part of a cash flow hedge. Therefore, ongoing tracking of the 10 tonnes is required to ensure appropriate recycling of the amounts previously taken to the cash flow hedge reserve (see section 7.2.2 above). This can get more complex in situations in which the hedging relationship needs frequent rebalancing, if not all hedged transactions occur at the same time, or in conjunction with the cost formulas used for the measurement of the cost of inventory (for example a first in first out formula) (see Chapter 23). In addition, risk management would normally adjust the quantity of the designated hedging instruments when rebalancing, since the hedged exposure is normally the 'given' and drives what hedges are needed.

When rebalancing a hedging relationship, an entity must update its analysis of the sources of ineffectiveness in the hedge documentation. [IFRS 9.B6.5.21].

8.3 Discontinuation

An entity must discontinue hedge accounting prospectively if either of the following occurs:

- The hedging relationship ceases to meet the qualifying criteria (after taking into account any rebalancing of the hedging relationship, if applicable) (see sections 8.1 and 8.2 above). An example would include where an eligible hedged item no longer exists (see section 8.3.4 below).

Or

- The hedging instrument expires or is sold, terminated, or exercised.

For the purpose of the second of these two occurrences, the replacement or rollover of a hedging instrument into another hedging instrument is not an expiration or termination if that is part of and consistent with a documented risk management objective, such as a rollover hedging strategy (see section 7.7 above).

There is a further exception, introduced when regulators began to mandate the clearing of over the counter derivatives through a central clearing house (see section 8.3.5 below).

These two occurrences are the only circumstances when a hedge is discontinued, as voluntary discontinuation is not permitted under IFRS 9.

Discontinuing hedge accounting can either affect a hedging relationship in its entirety or only a part of it (in which case hedge accounting continues for the remainder of the hedging relationship). [IFRS 9.6.5.6, IFRS 9.B6.5.22, IFRS 9.B6.5.25].

The table below summarises the main scenarios resulting in either full or partial discontinuation:

Scenario	Discontinuation
The risk management objective has changed (see section 8.3.3 below)	Full or partial
There is no longer an economic relationship between the hedged item and the hedging instrument (see section 6.4.1 above)	Full
The effect of credit risk dominates the value changes of the hedging relationship (see section 6.4.2 above)	Full
As part of rebalancing, the volume of the hedged item or the hedging instrument is reduced (see section 8.2 above)	Partial
The hedging instrument expires	Full
The hedging instrument is (in full or in part) sold, terminated or exercised	Full or partial
The hedged item (or part of it) no longer exists or is no longer highly probable (see section 8.3.4 below)	Full or partial

A logical consequence of linking the discontinuation to the risk management objective is that, as already mentioned, voluntary discontinuations are not permitted just for accounting purposes. In developing the standard, the IASB noted that hedge accounting is an exception to the general accounting principles in IFRS accounting standards, in order to (better) present in the financial statements a particular risk management objective of a risk management activity. If that risk management objective is unchanged and the qualifying criteria for hedge accounting are still met, a voluntary discontinuation would be inconsistent with the original (valid) reason for applying hedge accounting. [IFRS 9.B6.5.23]. The Board believes that hedge accounting, including its discontinuation, must have a particular meaning, rather than just be a mere accounting exercise. [IFRS 9.BC6.327]. Based on this, the IASB decided not to allow voluntary discontinuation for hedges with unchanged risk management objectives. [IFRS 9.BC6.331].

This change gave rise to concern among some constituents who argued that, given hedge accounting is optional, voluntary discontinuation should be permitted (as it was previously under IAS 39). [IFRS 9.BC6.324].

However, many of the circumstances in which an entity applying IAS 39 might have voluntarily discontinued hedge accounting do not arise in the same way under IFRS 9. For example, it is not necessary to discontinue hedge accounting in order:

- To adjust the hedge ratio for a change in the expected relationship between the hedged item and the hedging instrument (see section 8.2 above)
 - To hedge a secondary risk (e.g., where an entity first hedges the commodity price risk in a commodity purchase contract in foreign currency but later decides to hedge the foreign currency risk as well (see section 2.7 above))
 - To amend the chosen effectiveness method if it becomes no longer appropriate (see section 6.3 above)
- Or
- Because some of the hedged cash flows are no longer expected to occur (see section 8.3.4 below)

These circumstances are all addressed in IFRS 9 by inclusion of: rebalancing, the ability to achieve hedge accounting for aggregated exposures, no longer requiring hedges to be 'highly effective' and partial discontinuation. Hence, voluntary discontinuation is not needed in such situations.

It is important to note that the risk management objective of an individual hedging relationship can change although the risk management strategy of the entity remains unchanged (see section 6.2 above and section 8.3.3 below). [IFRS 9.BC6.330]. In fact, in most cases where an entity might wish to 'voluntarily dedesignate' a hedging relationship, this is usually driven by a change in the risk management objective, in which case the entity would actually be required to amend its hedge accounting under IFRS 9, for example when managing the risk from a portfolio on a dynamic basis (see section 8.3.3 below). The standard prohibits voluntary dedesignations when they are only made for accounting purposes.

As a result of the reforms mandated by the Financial Stability Board following the financial crisis, benchmark interbank offered rates (IBORs) such as LIBOR are being replaced by new 'official' benchmark rates, known as RFRs. Such a change will necessarily affect future cash flows in both contractual floating rate financial instruments currently referenced to IBOR, and highly probably forecast transactions for which IBOR is designated as the hedged risk. This raises a number of accounting questions, not least whether changes to the hedged or hedging instrument required by the reform might lead to the discontinuation of hedge relationships. In September 2019 and August 2020, the IASB issued amendments to IFRS 9 (and IAS 39) to address the accounting issues that arise as result of the reform (see the *Supplement: IBOR Reform*).

8.3.1 Accounting for discontinuation of fair value hedge accounting

On discontinuation of a hedge relationship for which the hedged item is a financial instrument (or component thereof) measured at amortised cost, any adjustment arising from a hedging gain or loss on the hedged item must be amortised to profit or loss. The amortisation is based on a recalculated effective interest rate at the date the amortisation begins (see section 7.1.2 above). The treatment of any fair value hedge adjustments on discontinuation must also be applied to partial discontinuations. [IFRS 9.6.5.10].

Illustration 8-4: Discontinuation of fair value hedge of term loan for interest rate risk

Entity A enters into a fixed rate term loan for £300m. The loan is for 5 years and pays interest annually at a rate of 5%. Given that the debt was issued at par with no premium, discount or fees, the effective interest rate is 5% (see Chapter 46).

A wishes to eliminate fair value variability due to changes in interest rate risk from the term loan and so at the same time also enters into an interest rate swap for £300m at the prevailing 5 year SONIA swap rate i.e., paying 3 month SONIA and receiving 3.5%.

A determines that all the criteria for hedge accounting are met and so designates the interest rate swap as the hedging instrument in a fair value hedge of the term loan with respect to changes in interest rate risk (see section 6 above).

After 1 year, the risk management objective of the hedge relationship changed such that A no longer wants protection from future changes in interest rates and so the interest rate swap is settled with the swap counterparty. A must discontinue the hedge relationship. Discontinuation is required in this case both because the hedging instrument no longer exists and because the risk management objective has changed, however, if only one of those circumstances arose, discontinuation would still be required (see section 8.3 above).

As the hedged item is no longer being adjusted for hedging gains and losses, a new effective interest rate is recalculated and amortisation using the new effective interest rate begins. [IFRS 9.6.5.10]. At that time the carrying amount of the hedged item included a fair value hedge adjustment of £25m, i.e., total carrying amount of the fixed rate term loan was £325m. A must now recalculate the effective interest rate of the fixed rate term loan, reflecting the carrying amount £325m and 4 remaining years of cash flows at 5%.

This equates to a new effective interest rate of 2.8% (i.e., $\text{£}325\text{m} = (\text{£}15\text{m}/(1.028)) + (\text{£}15\text{m}/(1.028^2)) + (\text{£}15\text{m}/(1.028^3)) + (\text{£}315\text{m}/(1.028^4))$) which will be used to measure the loan at amortised cost until maturity or derecognition.

In the case of a debt instrument (or component thereof) that is a hedged item measured at fair value through other comprehensive income (see section 7.1.1 above), the amortisation is applied in the same manner as for financial instruments measured at amortised cost, but to other comprehensive income instead of by adjusting the carrying amount. [IFRS 9.6.5.10].

On discontinuation of a fair value hedge for which the hedged item is not a financial instrument, the entity ceases to make any further adjustment arising from a hedging gain or loss on the hedged item, and any previous adjustment from fair value hedge accounting becomes part of the carrying amount of the hedged item, as per the general requirements when accounting for fair value hedges (see section 7.1.1 above).

[IFRS 9.6.5.8(b)].

If the hedged item no longer exists, which might be the reason the hedge relationship has been discontinued (see section 8.3.4 below), any hedging gain or loss on the hedged item will be accounted for on application of the usual derecognition guidance for the hedged item, as the gain or loss forms part of its carrying amount.

8.3.2 Accounting for discontinuation of cash flow hedge accounting

When an entity discontinues hedge accounting for a cash flow hedge, it must account for the amount that has been accumulated in the cash flow hedge reserve as follows:

- The amount remains in accumulated OCI if the hedged future cash flows are still expected to occur
- Or
- The amount is immediately reclassified to profit or loss as a reclassification adjustment if the hedged future cash flows are no longer expected to occur [IFRS 9.6.5.12]

After discontinuation, once the previously expected hedged cash flow occurs, any amount remaining in accumulated OCI must be accounted for depending on the nature of the underlying transaction consistent with the accounting for cash flow hedge relationships that are not discontinued (see section 7.2.2 above). [IFRS 9.6.5.12]. The treatment of the cash flow hedge reserve on discontinuation must also be applied to partial discontinuations.

Illustration 8-5: Discontinuation of cash flow hedge of term loan for interest rate risk

Entity X enters into a floating rate term loan for €500m. The loan is for 8 years and pays 3 month ESTR plus a credit spread of 200bp. X wishes to eliminate cash flow variability due to changes in interest rate risk from the term loan and so at the same time also enters into an interest rate swap for €500m at the prevailing 8 year ESTR rate i.e., receiving 3 month ESTR and paying 4.5% quarterly.

X determines that all the criteria for hedge accounting are met and so designates the interest rate swap as the hedging instrument in a cash flow hedge of the term loan with respect to changes in interest rate risk (see section 6 above).

After 2 years, the risk management objective of the hedge relationship changed such that X no longer wants protection from changes in interest rates and so the interest rate swap is settled with the swap counterparty. X must discontinue the hedge relationship. Discontinuation is required in this case both because the hedging instrument no longer exists and because the risk management objective has changed, however, if only one of those circumstances arose, discontinuation would still be required (see section 8.3 above).

At that time an amount of €36m had accumulated in the cash flow hedge reserve. X still expected the term loan to continue for the remaining 6 years. Although X is no longer protected from future changes in interest rate risk, in order to reflect the protection it received when the hedge relationship existed, X must recycle the amount accumulated in the cash flow hedge reserve to profit and loss as the hedged expected future cash flows affect profit or loss. [IFRS 9.6.5.11(d)(ii)].

X recycles the €36m from cash flow hedge reserve to profit or loss over the remaining 6 years of the hedged cash flows. X applies this reclassification on a straight-line basis, i.e., €6m per annum, as a proxy for the effect of hedge accounting on future hedged cash flows.

After another year X expects a future influx of capital such that the term loan will not be required for its full maturity. X now expects to repay the term loan within 2 years, i.e., 3 years earlier than expected. In that case the hedged cash flows relating to the final 3 years of the term loan are no longer expected to occur and hence the accumulated amounts in the cash flow hedge reserve related to those cash flows must be immediately reclassified into profit or loss. [IFRS 9.6.5.12(b)].

Of the remaining €30m accumulated in cash flow hedge reserve, €18m (i.e., €6m x 3 years) relates to the final 3 years of the original term of the loan and hence should be immediately reclassified to profit or loss.

8.3.3 Change in risk management objective

An entity must discontinue hedge accounting prospectively for a hedge relationship if there is a change in the risk management objective for that hedge relationship (see section 8.3 above). [IFRS 9.B6.5.22]. A change in risk management objective must be a matter of fact that can be observed in the entity's actual risk management (see section 6.2 above). The examples below, the first of which is derived from the application guidance to IFRS 9, demonstrate how this could be assessed in practice. [IFRS 9.B6.5.24].

Illustration 8-6: Partial discontinuation as a result of a change in risk management objective

ABC Ltd is currently fully financed with variable rate borrowings (the tables in this example show nominal amounts in millions of euro (EUR)):

Non-current financial liabilities as of 1 January 20X1	Variable rate	Fixed rate
Variable rate borrowings	100	
Fixed rate borrowings		0
Total	100	0
	100%	0%

Risk management strategy

To maintain between 20% and 40% of long term debt at a fixed rate.

Risk management activity

To implement the strategy, the treasurer of ABC enters into a pay fixed/receive variable interest rate swap (IRS) with a notional amount of EUR30m and designates the IRS in a hedging relationship.

Risk management objective

Use a pay fixed/receive floating interest rate swap with a notional amount of EUR30m in a cash flow hedge of the interest payments on EUR30m of the variable rate borrowings in order to maintain 30% of the long-term borrowings at a fixed rate.

Non-current financial liabilities as of 1 January 20X1	Variable rate	Fixed rate
Variable rate borrowings	100	
Fixed rate borrowings		0
Pay fixed/receive variable interest rate swap	(30)	30
Total	70	30
	70%	30%

On 31 March 20X2, the entity needs further funding and takes advantage of lower interest rates by issuing a EUR50m fixed rate bond. At the same time, the entity decides to set its fixed rate exposure at 40% of total borrowings, still being within the existing risk management strategy.

Non-current financial liabilities as of 31 March 20X2	Variable rate	Fixed rate
Variable rate borrowings	100	
Fixed rate borrowings		50
Pay fixed/receive variable interest rate swap	(30)	30
Total	70	80
	47%	53%

It is evident that ABC is no longer within the target range of its risk management strategy. In order to execute the risk management strategy, ABC no longer needs part of its interest rate swap. In other words, the risk management objective for the hedging relationship has changed. Consequently, ABC discontinues EUR20m of the hedging relationship (a partial discontinuation). ABC could close out the risk from EUR20m of the IRS or ABC could choose to use the EUR20m of the IRS to hedge a different exposure or to transfer it to a trading book.

Going forward, ABC's debt financing and risk profile will be as follows: [IFRS 9.B6.5.24(a)]

Non-current financial liabilities as of 31 March 20X2	Variable rate	Fixed rate
Variable rate borrowings	100	
Fixed rate borrowings		50
Pay fixed/receive floating interest rate swap	(10)	10
Total	90	60
	60%	40%

The above example only illustrates the outcome of one particular course of action. The entity could also have adjusted its interest rate exposure in a different way in order to remain in the target range for its fixed rate funding, for instance by swapping EUR20m of the new fixed rate bond into variable rate funding. In that case, instead of discontinuing a part of the already existing cash flow hedge, the entity could have designated a new fair value hedge. The example in the application guidance of the standard is obviously a simplified one. In practice, entities tend to have staggered maturities for different parts of their financing. In such situations it would often be obvious from the maturity of the new interest rate swaps if they are a fair value hedge of the debt or a reduction of the already existing cash flow hedge volume. For example, if the new EUR50m fixed rate bond is for a longer period than the existing debt and the new interest rate swap is for the same longer period, it would suggest that it is a fair value hedge of the new fixed rate bond instead of a reduction of the cash flow hedge for the already existing debt. Conversely, a reduction of the cash flow hedge volume would be consistent with entering into a new interest rate swap that has the same remaining maturity as the existing interest rate swap and offsets its fair value changes on a part of the notional amount. Whichever way an entity chooses to incorporate a change in risk management activity into its hedge accounting solution, it must be directionally consistent with its risk management strategy (see section 6.2.1 above).

Illustration 8-7: Partial discontinuation of an interest margin hedge

XYZ Bank is holding a combination of fixed and variable rate assets and liabilities on its banking book. For risk management purposes, the bank allocates all the assets and liabilities to time bands based on their contractual maturity. As of 1 January 20X1 the bank holds the following instruments in the 5-year time band (the tables in this example show nominal amounts in millions of euro (EUR)). For simplicity the example only reflects a single time band. In reality this is highly unlikely to be the case. Further, the risk management activity is also simpler than might be the case when considering numerous time bands:

Summary of instruments with a 5-year maturity	Assets: fixed rate	Liabilities: fixed rate	Assets: variable rate	Liabilities: variable rate
Bonds held			20	
Mortgages	30		10	
Retail loans	30		10	
Client term deposits				(60)
Bonds issued		(30)		(10)
Total	60	(30)	40	(70)
Fixed-variable interest mismatch	30	(30)		

The fixed-variable mismatch results in interest margin risk due to changes in interest rates.

Risk management strategy

To eliminate the interest margin risk resulting from fixed-variable interest mismatches.

Risk management activity

In order to achieve the risk management strategy, XYZ Bank enters into a pay fixed/receive variable interest rate swap (IRS) with a notional amount of EUR30m. For accounting purposes, the bank could either designate the IRS in a cash flow hedge of EUR30m of specific variable rate liabilities or in a fair value hedge of EUR30m of specific fixed rate assets (see section 6.2.1 above). Under the local regulatory requirements, fair value hedges are more favourable for the bank's regulatory capital.

Risk management objective

Using a EUR30m pay fixed/receive variable IRS in a fair value hedge of EUR30m of fixed rate retail loans to hedge a fixed-variable interest mismatch on fixed and variable rate assets and liabilities in the 5-year time band of XYZ Bank's banking book.

At the beginning of year 20X3, XYZ Bank attracts EUR10m of client term deposits as a result of a successful marketing campaign. The new term deposits all have a fixed interest rate for a maturity of three years, therefore, matching the (remaining) maturity of the instruments in the above time bucket. The XYZ Bank uses the proceeds from the new term deposits to buy back EUR10m of variable rate bonds that it has issued. The new situation in the (now) 3-year time band is:

Summary of instruments with a 3-year maturity	Assets: fixed rate	Liabilities: fixed rate	Assets: variable rate	Liabilities: variable rate
Bonds held			20	
Mortgages	30		10	
Retail loans	30		10	
Client term deposits		(10)		(60)
Bonds issued		(30)		(0)
Total	60	(40)	40	(60)
Fixed-variable interest mismatch	20		(20)	
Pay fixed/receive variable interest rate swap		(30)	30	

As a result of the change in funding, the risk management objective of the hedging relationship has changed. XYZ Bank is over-hedged and needs to discontinue EUR10m of its hedging relationship. Even though there is no change in the designated hedged items themselves, given that XYZ Bank's risk management strategy is to consider all interest margin risk, the risk management objective for the designated hedge has changed.

As stated above, whether the risk management objective has changed for a particular hedge relationship will be a matter of fact, and for many scenarios this will be obvious, as demonstrated in Illustration 8-6 and Illustration 8-7 above. However, for more complex risk management approaches, judgement will be required to determine whether the risk management objective has changed or not. An example would be when managing the risk from a portfolio on a dynamic basis but for which 'proxy' hedge accounting relationships have been designated (see section 6.2.1 above). The application guidance in IFRS 9 provides an example of how a change in the risk management objective is considered for a dynamic risk management approach.

Illustration 8-8: Change in risk management objective for an open portfolio of debt instruments

An entity manages the interest rate risk of an open portfolio of debt instruments. The resultant exposure from the open portfolio frequently changes due to the addition of new debt instruments and the derecognition of debt instruments (i.e., it is different from simply running off a position as it matures). Entity A applies a dynamic process in which both the exposure and the hedging instruments used to manage it do not remain the same for long. Consequently, Entity A frequently adjusts the hedging instruments used to manage the interest rate risk as the exposure changes. For example, debt instruments with 24 months' remaining maturity are designated as the hedged item for interest rate risk for 24 months. The same procedure is applied to other time buckets or maturity periods. After a short period of time, Entity A discontinues all, some or a part of the previously designated hedging relationships and designates new hedging relationships for maturity periods on the basis of their size and the hedging instruments that exist at that time. The discontinuation of hedge accounting in this situation reflects that those hedging relationships are established in such a way that Entity A looks at a new hedging instrument and a new hedged item instead of the hedging instrument and the hedged item that were designated previously. The risk management strategy remains the same, but there is no risk management objective that continues for those previously designated hedging relationships, which as such no longer exist.

In such a situation, the discontinuation of hedge accounting applies to the extent to which the risk management objective has changed. This depends on the situation of an entity and could, for example, affect all or only some hedging relationships of a maturity period, or only part of a hedging relationship.

[IFRS 9.B6.5.24(b)].

The above example would, in particular, appear to be relevant if an entity with a dynamic risk management approach to interest rate risk within an open portfolio designates its risk management activity as a macro cash flow hedge (see section 10.2 below). A change in risk management objective might also occur in the case of a closed portfolio for which the managed risk has changed such that the entity looks to new hedging derivatives to meet the risk management strategy, for example if managing the duration risk from a portfolio of fixed rate loans to within particular risk limits (see Illustration 6-1 in section 6.2 above).

The situation is further complicated if a financial institution initiates risk management activity using internal derivatives. For example, interest rate risk from general banking activities could be managed centrally by a Group treasury function by transferring risk positions via internal derivatives to a Trading function. The Trading function would assume the interest rate risk from the internal derivatives within their trading book and transact external derivatives accordingly to match the trading desk limits and strategy. Hedge accounting can only be achieved to the extent that external derivatives are designated as hedging instruments of eligible hedged item within the general banking activities, as a proxy hedge (see sections 4.2.1 and 6.2.1 above).

The Group treasury could subsequently wish to change its interest rate risk position with the Trading function, perhaps due to a change in view of the shape of the relevant yield curve. In that case the Group treasury might amend the existing internal derivatives with the Trading function. The amended internal derivatives will impact the risk position managed by the Trading function but would not necessitate an equivalent change to any external derivatives. It appears clear that the Group treasury has changed its risk management objective for certain hedged items. However, as Group treasury only 'hedge' their risk via internal derivatives there is a question as to whether any designated proxy hedge relationships can be discontinued without any associated change to the external derivatives. Judgement is required, but if there is a clear change in risk management objective for particular hedged items within Group treasury, and the Trading function has autonomy to manage their own trading risk position including any internal derivatives, that could be sufficient to determine that the risk management objective for those hedged items designated in a proxy hedge has changed (or partially changed) and the hedge must be discontinued (or partially discontinued).

8.3.4 Documented hedged item no longer exists

Hedge accounting is only permitted for eligible hedged items, hence hedge accounting must be discontinued if the hedged item no longer exists (see section 8.3 above). Partial discontinuation is required if only a part of the hedged item no longer exists. [IFRS 9.6.5.6]. For partial discontinuations, it is important that the hedge relationship containing the remaining hedged item continues to meet the qualifying criteria in order to continue hedge accounting (see section 6 above).

Specific guidance is provided on the accounting for the adjustment arising from a hedging gain or loss on the hedged item in a fair value hedge or the amount accumulated in OCI in a cash flow hedge on discontinuation of a hedge relationship (see sections 8.3.1 and 8.3.2 above).

In many cases it will be straight forward to determine whether the hedged item exists or not, but in all cases that determination will need to be made with respect to the documented description of the hedged item made on initial designation (see section 6.3 above). The importance of the initial documentation of hedged items and the impact it can have over the life the hedge relationship is illustrated below in Illustration 8-9, Illustration 8-10 and Illustration 8-11. In all the examples below, it is assumed that the qualifying criteria for application of hedge accounting are met on initial designation (see section 6 above).

Illustration 8-9: Interruption of hedged forecast cash flows

An entity with sterling as its functional currency documents the designation of its forecast euro highly probable sales of €100,000 each month throughout 20X2 as hedged items in a cash flow hedge of the risk of changes in foreign currency rates (see sections 2.6.1 and 6.3.3 above). It hedges these sales by entering into a series of forward foreign currency contracts, one for each month. Business is severely interrupted for a number of months (e.g., from a fire in the warehouse or a global pandemic) such that sales in May, June and July are now expected to be zero. The hedged cash flows for May, June and July therefore no longer exist. Hedge accounting for those cash flows must be discontinued and the associated amounts in OCI recycled to profit or loss immediately. This is despite the fact that the entity could have unhedged euro sales in subsequent months, as they do not meet the description of the hedged item as documented. This is the case even if there is a belief that greater than originally expected euro sales in subsequent months would arise as a catch up of sales that did not take place in earlier months.

Illustration 8-10: Change in forecast hedged item

Entity X, a specialist supplier and fitter of luxury vehicles, with euro functional currency has negotiated a sale of a bespoke luxury yacht. It is highly probable the sale will be made to a particular US customer in September 20X2. Given the customized nature of the yacht specifications and the currency of the customer, the sales price was negotiated in US dollars (see section 2.2.5 above). Entity X designates the highly probable forecast sale of the bespoke luxury yacht for USD10m as the hedged item in a cash flow hedge of the risk of changes in foreign currency rates.

Subsequently the sale is delayed due to delivery issues, and it is now expected to occur in December 20X2. Although the expected timing has changed, the sale of the bespoke luxury yacht to the particular US customer is still highly probable and so the documented hedged item still exists. The change in timing could however result in some additional ineffectiveness (see sections 7.4.2 and 7.4.4 above).

Whilst Illustration 8-9 and Illustration 8-10 above both include a scenario in which the expectations of the entity undertaking the risk management activity have changed with respect to timing of foreign currency cash flows, it can be seen that the outcome for the hedge relationship is quite different. In Illustration 8-9 in which the hedged item is defined by its timing, i.e., sales in May, June and July 20X2, a change in timing would redefine the hedged item such that it is different to the original documented hedged item. By contrast, in Illustration 8-10 the definition of the hedged item is the highly probable sale of a bespoke luxury yacht itself. The time period in which a forecast transaction is expected to occur must be identified and documented within a reasonably specific and generally narrow range of time from a most probable date in order to determine that the forecast transaction is highly probable (see section 6.3.3 above).

[IAS 39.F.3.11]. However, a change in the estimate of the timing of the sale of a bespoke luxury yacht does not of itself redefine the hedged item, hence it is still highly probable the original hedged item will occur.

Illustration 8-11: Change in hedged forecast debt issuance

As at 1 January 20X2 Entity A expects to issue highly probable 10 year floating rate debt in June 20X2. In order to hedge cash flow variability from changes in SONIA, Entity A transacts a forward starting 10 year pay fixed, receive SONIA interest rate swap (IRS) from June 20X2. The IRS is designated in a cash flow hedge for changes in SONIA interest rates.

There are a number of ways in which the hedged item (i.e., the forecast debt) might be documented for that hedge relationship. For the purposes of illustration, set out below are two possible ways key aspects of the hedged items might be described in the documentation. Additional information, not provided here, is likely to be required in order to meet all of the requirements of the standard (see section 6.3 above):

- (a) The variability of cash flows on 10 year £100m debt expected to be issued in June 20X2 attributable to the risk of changes in SONIA

Or

- (b) The variability of cash flows arising on forecast GBP interest flows (based on £100m principal) between June 20X2 and June 20X2, attributable to the risk of changes in SONIA

Let us now consider various scenarios that might arise sometime after designation of the hedge relationship, and how the documentation of the hedged item would affect the outcome for hedge accounting:

- (i) £100m debt was issued in June 20X2, but at a fixed interest rate based on SONIA plus a spread

For both a) and b) it appears the documented hedged item still exists.

However, it is likely that the IRS would be closed out once the debt was issued. This would have no bearing on the hedge relationship, which would already have ended as there is no further variability in cash flows from the issued fixed rate debt. As the hedged items are still expected to occur, the amount accumulated in OCI must be reclassified from the cash flow hedge reserve to profit or loss as a reclassification adjustment in the periods that interest expense is recognised in profit or loss (see section 7.2.2 above).

- (ii) £100m floating rate debt (monthly coupons) was issued in September 20X2

If the issued debt met the description under a) in all areas other than timing, it is likely that the hedged item in a) still exists. However, some ineffectiveness will arise due to the change in timing of the hedged item. This case is similar to that of the specialist supplier and fitter of luxury vehicles in Illustration 8-10 above, for which the forecast sale of the bespoke luxury yacht was delayed. In both cases, the identification of the documented hedged item was defined by the transaction itself, rather than its timing.

For hedged item b) the hedged interest flows from June to August 20X2 do not exist (similar to the conclusion in Illustration 8-9 above), but the remaining interest flows until June 20X2 are still highly probable of occurring. Assessment of the effectiveness requirements and measurement of ineffectiveness must reflect the fact that the June to August 20X2 flows no longer exist. If a hypothetical derivative is used for assessment and measurement purposes it will need to be updated to reflect the fact that no interest flows will occur from June to August 20X2 (see section 7.4.4 above). This will lead to an additional source of ineffectiveness which must be considered within the economic relationship assessment and is likely to lead to the recognition of ineffectiveness (see sections 6.4.1 and 7.2.1 above). Any amounts remaining in OCI relating to the June to August 20X2 cash flows that are no longer expected to occur must be recycled immediately to profit or loss (see section 8.3.2 above).

It can be seen that documentation of the hedged item on initial designation requires careful consideration, as it is a key determinant through the life of the hedge relationship as to whether the hedged item continues to exist.

Although it might seem potentially beneficial to be intentionally vague when documenting a hedged item in order to reduce the possibility that some unforeseen circumstance might require discontinuation of a hedge relationship, the documentation must be sufficiently specific in order to ascertain whether the hedged item has occurred or not. Having said that, this does not mean the hedge documentation needs to specify the hedged item in every single detail. As mentioned above, the key aim of the documentation is to provide clarity as to whether the hedged item has occurred or not, hence a balance needs to be struck to achieve an appropriate level of specificity. The Implementation Guidance within IAS 39 contained some guidance on the need for sufficient specificity of the documented hedged item, this guidance can be considered relevant for IFRS 9 hedge accounting (see section 6.3 above). [IAS 39.F.3.10, IFRS 9.BC6.200].

The examples above all relate to highly probable forecast transactions, however the requirement to consider changes in the hedged item can also arise for recognised hedged items. This is illustrated below in Illustration 8-12.

Illustration 8-12: Change in hedged recognised variable rate debt

In 20X1 Entity B issued 100m of euro denominated 7 year variable rate debt paying €STR plus a spread. At the same time Entity B entered into a EUR100m interest rate swap receiving €STR and paying a fixed rate of interest. The swap was designated as a hedging instrument in a cash flow hedge of the variability in interest payable on the EUR100m debt with respect to changes in interest rates. It is assumed that the qualifying criteria for application of hedge accounting are met on initial designation (see section 6 above).

In 20X2, a product that Entity B has developed is proving very successful and in June 20X2 it unexpectedly receives a number of very lucrative offers to buy out the product. If an offer were accepted and settled then Entity B would no longer have need of the EUR100m debt and would repay the debt at par (as per the terms of the debt).

Even though the hedged variability is from a recognised instrument rather than a highly probable forecast one, there is still a requirement to consider whether the variability of the hedged item will occur. The importance of this consideration was evidenced in the IASB's discussion on the amendments to IFRS 9 for IBOR reform, for which the amendment was required to reflect uncertainty in the variability of both forecast and recognised IBOR related financial instruments (see the *Supplement: IBOR Reform*).

In this case, even though Entity B has not yet repaid the EUR100m debt, an assessment must be made in June 20X2 as to whether all the hedged future interest payments arising on the debt are highly probable or not. This will require judgement and would clearly need to consider management's plans for the sale of the product (see section 2.6.1 above). It is not acceptable to wait until a final decision is made on the potential sale and subsequent debt repayment.

It could be that management is not able to determine that certain interest payments are highly probable, which will result in a (partial) discontinuation of the hedge relationship (see section 8.3 and Illustration 8-5 in section 8.3.2 above). However, those interest payments might still be expected to occur (a lower hurdle than highly probable), in which case the amounts accumulated in OCI relating to those interest payments will remain there until they occur or are no longer expected to occur (see section 8.3.2 above).

8.3.5 Impact of novation to central clearing parties on cash flow hedges

The collapse of some financial institutions during the financial crisis highlighted the potential impact of credit risk on the global derivatives markets. In response to this, several jurisdictions introduced, legal or regulatory requirements that require or incentivise over-the-counter (OTC) derivatives to be novated to a central clearing party (CCP). The CCP would usually require the derivatives to be collateralised, thereby reducing (potentially significantly) the counterparty credit risk.

Following an urgent request, the IFRS IC concluded in January 2013 that an entity is required to discontinue hedge accounting where an OTC derivative that is designated as hedging instrument in a hedging relationship is novated to a CCP (unless, very unusually, the novation represented a replacement or rollover of the hedging instrument as part of a documented hedging strategy (see section 7.7 above)). This is because the novated derivative is derecognised and the new derivative contract, with the CCP as a counterparty, is recognised at the time of the novation. [IFRS 9.BC6.336]. However, if the new derivative was designated in a cash flow hedge relationship accounting ineffectiveness would likely arise if the derivative is off market (see section 7.4.3 above). Consequently, the IFRS IC decided to recommend that the IASB make a narrow-scope amendment to IAS 39 to permit continuation of hedge accounting in such narrow circumstances.³¹ In July 2013 the IASB amended IAS 39 after the publication of an exposure draft in February 2013 and the changes were also incorporated in IFRS 9 when the hedge accounting chapter was added in November 2013.

31 [IFRIC Update](#), January 2013, available on the IFRS Foundation's website.

The relevant guidance in IFRS 9 states that an expiration or termination of the hedging instrument does not require discontinuation of the hedge relationship if:

- As a consequence of changes in laws or regulations, the original counterparty to the hedging instrument is replaced by a clearing counterparty (sometimes called a 'clearing organisation' or 'clearing agency') or a clearing member of a clearing organisation or a client of a clearing member of a clearing organisation, that are acting as counterparty in order to effect clearing by a central counterparty.
 - Each of the original counterparties to the hedging instrument effects clearing with the same central counterparty.
- And
- Other changes, if any, to the hedging instrument are limited to those that are necessary to effect such a replacement of the counterparty. Such changes are limited to those that are consistent with the terms that would be expected if the hedging instrument were originally cleared with the clearing counterparty. These changes include changes in the collateral requirements, rights to offset receivables and payables balances, and charges levied. [IFRS 9.6.5.6].

It can be seen from the guidance that the exception applies to some, but not all, voluntary novations to a CCP. In order for hedge accounting to continue, a voluntary novation must at least be associated with laws or regulations that are relevant to central clearing of derivatives. For example, a voluntary novation could be in anticipation of regulatory changes. However, the mere possibility of laws or regulations being introduced is not, in the view of the IASB, a sufficient basis for continuation of hedge accounting. [IFRS 9.BC6.349]. So, a novation needs to be required by laws or regulations (or at least associated with a change in law or regulations) for hedge accounting to be continued, allowing all novations to CCPs to be accommodated would be wider than the IASB had intended. [IFRS 9.BC6.347].

Further, the exception also applies to so-called 'indirect clearing' arrangements whereby a clearing member of a CCP provides an indirect clearing service to its client or where a group entity is clearing on behalf of another entity within the same group since they are consistent with the objective of the amendments. [IFRS 9.BC6.348].

A further impact of novating derivatives to a CCP is that the derivatives are likely to become collateralised by cash. The July 2013 amendments to IFRS 9 acknowledged this and provided clarity that such a change on novation to a CCP would not result in derecognition if such changes are limited to those that are consistent with the terms that would be expected if the hedging instrument were originally cleared with the clearing counterparty. [IFRS 9.6.5.6(b)].

Cash collateralisation significantly reduces the credit risk for both parties involved, which will influence the fair value of derivatives novated. The application guidance clarifies that the change in the fair value of the hedging instrument that results from the changes to the contract in connection with the novation (e.g., a change in the collateral arrangements) must be included in the measurement of hedge ineffectiveness. [IFRS 9.B6.4.3].

The other criteria for achieving hedge accounting will still need to be met in order to continue hedge accounting (see in section 6 above).

The amendment was only designed to be a narrow-scope amendment for the specific situation of novation of certain derivatives to a CCP associated with laws or regulation that are relevant to the clearing of derivatives, hence it must not be applied more widely to other scenarios. [IFRS 9.BC6.347].

8.3.6 Settle to market derivatives within cash flow hedges

In December 2015, the London Clearing House (LCH) changed its rule book to introduce a new type of settled-to-market (STM) interest rate swap in addition to the previously existing collateralized-to-market (CTM) swaps.

In the existing CTM model, transactions cleared through LCH were subject to daily cash variation margining. This means that the replacement value of the trade is in effect paid or received as cash each day and there is no ability to recover any of the variation margin unless the fair value of the interest rate swap changes. In addition, the variation margin is also used to settle the periodic swaps payments, and, in case of early settlement, the variation margin is used to settle the outstanding derivative position. Interest is paid on the variation margin based on a risk-free overnight rate.

In the STM model, transactions have the same economic exposure and overall cash flows as in the CTM model, except that the previous daily variation margin is now treated as a settlement of the interest rate swap's outstanding fair value. While the swap is gradually settled, it remains the same swap with the same original terms (e.g., the fixed rate, maturity date etc.). Hence, the daily settlement under the STM model of a derivative designated as the hedging instrument in a hedge relationship does not mean it has expired or terminated, and so does not result in discontinuation of the hedge relationship (see section 8.3 above). In order to maintain the same economics, a new feature of the STM swap pricing is the Price Alignment Interest (PAI) that essentially replicates what would have been the interest on the collateral for a CTM swap into the STM swap pricing.

8.3.7 Change of hedging counterparty within the same consolidated group

An entity might be required to, or choose to, novate a hedging instrument from one entity within a consolidated group, to another entity within the same group. For example, following the vote by the United Kingdom to leave the European Union in June 2016, commonly known as 'Brexit', Corporate A (the hedging entity) might plan to novate existing hedging derivatives with Bank UK (the hedging counterparty entity), to Bank EU, both Bank UK and Bank EU are subsidiaries of the same global banking group. Alternatively, a banking group might undertake an internal reorganisation such that a portfolio of derivatives (or a whole business) is transferred into a different entity within the same banking group. In both instances a question arises as to whether such a change in hedging derivative counterparty will result in the discontinuation of a hedge relationship.

We set out below the accounting requirement from the perspective of the various parties in the fact pattern - on the assumption that all parties designate the novated derivative in an eligible hedge relationship, consistent with their risk management objective.

- In the standalone financial statements of the original hedging counterparty, (i.e., Bank UK in the Brexit example above), it is clear that a hedge relationship would be discontinued, as an eligible hedging instrument no longer exists within that hedging counterparty legal entity.
- In the standalone financial statements of the new hedging counterparty (i.e., Bank EU in the Brexit example above), it is clear that a new hedge relationship would need to be designated (including identification of an eligible hedged item), as this entity is not party to the instrument designated in the previous hedge relationship (unless the derivative and designated hedged item were both included in a business transferred as part of the common control transaction (see Chapter 11)).
- In the consolidated financial statements of a parent that consolidates both the original hedging counterparty (i.e., Bank UK) and the new hedging counterparty (i.e., Bank EU), (i.e., the global banking group in the Brexit example above) the hedge relationship will continue. This is because an entity first consolidates all subsidiaries and then applies the derecognition guidance to financial instruments. [IFRS 9.3.2.1]. Accordingly, the hedging derivative still exists within the consolidated financial statement, hence there is no requirement to discontinue the hedge relationship.
- From the perspective of the hedging entity (i.e., Corporate A), the transfer of a derivative from one counterparty to another would ordinarily result in derecognition and hence a de-designation and re-designation of a hedge relationship (see section 8.3.5 above). However, the appropriate treatment will depend on the specific facts and circumstances.

8.3.8 Disposal of a hedged net investment

The amount relating to a net investment hedge that has been accumulated in the foreign currency translation reserve must be reclassified from equity to profit or loss as a reclassification adjustment on disposal or, in certain circumstances, partial disposal of the foreign operation in accordance with IAS 21 (see Chapter 16 and section 7.3 above). [IFRS 9.6.5.14].

When a foreign operation that was hedged is disposed of, the amount reclassified from the foreign currency translation reserve to profit or loss is as follows:

- In respect of the hedging instrument in the consolidated financial statements, the cumulative gain or loss on the hedging instrument that was determined to be an effective hedge (see section 7.3.1 above) [IFRIC 16.16]
And
- In respect of the net investment, the cumulative amount of exchange differences relating to that foreign operation [IAS 21.48, IFRIC 16.17]

If an intermediate parent exists within the ultimate consolidation group, there is a choice of applying either the direct or step-by-step method of consolidation (see Chapter 16). If the step-by-step method of consolidation is used, the cumulative amount of exchange differences relating to that foreign operation accumulated in the foreign currency transaction reserve could be different to the equivalent amount had the direct method of consolidation been applied. This potential difference in the accounting outcome on disposal of a foreign operation is illustrated in Illustration 8-13 below.

This difference in accounting treatment could be eliminated, but there is no requirement to do so. An accounting policy choice must be taken as to whether the difference is eliminated or not, and such a choice must be applied consistently on disposal of all net investments. [IFRIC 16.17].

Illustration 8-13: Disposal of foreign operation

Consider the same facts as in Illustration 5-3 and Illustration 5-4 in sections 5.3.1 and 5.3.2 above. In summary, Company P is the ultimate parent entity of a group and presents its consolidated financial statements in its functional currency of euro. It has two direct wholly owned subsidiaries, Company A whose functional currency is Japanese yen and Company B whose functional currency is sterling. B has a wholly owned subsidiary, Company C, whose functional currency is US dollars. P's net investment in A is ¥400,000 million. P's net investment in B is £500 million including the equivalent of £159 million representing B's net investment in C of US\$300 million. The group has designated US\$300 million of US dollar borrowings of A as a hedge of the net investment in C with the risk being the spot foreign currency exposure (€/US\$) between P and C. If C were disposed of, the amounts reclassified to profit or loss in P's consolidated financial statements from its foreign currency translation reserve would be: [IFRIC 16.16, IFRIC 16.17, IFRIC 16.AG8]

- In respect of A's borrowing (the hedging instrument), the total change in value in respect of foreign currency risk that was recognised in other comprehensive income as the effective portion of the hedge (i.e., the retranslation effect on the US\$300 million borrowing with respect to the EUR/USD foreign currency rate since initial designation).
And
- In respect of the net investment in C, the amount determined by the entity's consolidation method:
 - If P uses the direct method, its foreign currency translation reserve ('FCTR') in respect of C will be determined directly by the EUR/USD foreign currency rate.
 - If P uses the step-by-step method, its FCTR in respect of C will be determined by the FCTR recognised by B reflecting the GBP/USD foreign currency rate, translated to P's functional currency using the EUR/GBP foreign currency rate.
- P's use of the step-by-step method for consolidation in prior periods does not require it to or preclude it from determining the amount of FCTR to be reclassified when it disposes of C to be the amount that it would have recognised if it had always used the direct method. However, it is an accounting policy choice which should be followed consistently on disposal of all net investments.

9 Presentation

For a comprehensive overview of the financial instruments related presentation requirements of IFRS 7 *Financial Instruments: Disclosures*, see Chapter 50 (for hedge accounting presentation requirements). We present below only some of the key requirements for hedge accounting.

IFRS 9 includes plenty of guidance as to when gains and losses from hedge accounting must be recognised in profit or loss. The standard is much less precise as to where in the profit or loss such gains and losses are presented. However, it can be inferred that gains and losses from hedging instruments in hedging relationships would normally be presented in the same line item that is affected by the hedged item (at least to the extent the hedge is effective), rather than being shown separately, although this is not explicitly stated in IFRS 9 (see Chapter 50).

The IFRS IC clarified in March 2018 that only interest on financial assets measured at amortised cost or on debt instruments measured at fair value through other comprehensive income are permitted to be included in the amount of interest revenue presented separately for items calculated using the effective interest method (see Chapter 50). [IAS 1.82(a), IFRS 18.75(b)(i)]. At this meeting it was also concluded that the separate interest revenue line would encompass the effect of a qualifying hedge of interest rate risk, applying the hedge accounting requirements.³²

9.1 Cash flow hedges

IFRS 9 requires that those amounts accumulated in the cash flow hedging reserve are reclassified from the cash flow hedge reserve as a reclassification adjustment in the same period or periods during which the hedged future cash flows affect profit or loss. The guidance provides as an example of the period over which such a reclassification must occur, as the “periods that interest income or interest expense is recognised” (see section 7.2.2 above). [IFRS 9.6.5.11(d)(ii)]. This clarifies that entities cannot simply account for the net interest payment on an interest rate swap straight into profit or loss but would have to present this as a reclassification adjustment between OCI and profit or loss. There is a requirement to disclose reclassification adjustments in the statement of comprehensive income (see Chapter 50). [IAS 1.92, IFRS 18.90].

If the hedged transaction subsequently results in the recognition of a non-financial item, the amount accumulated in equity is removed from the separate component of equity and included in the initial cost or other carrying amount of the hedged asset or liability. This accounting entry, sometimes referred to as ‘basis adjustment’, does not affect OCI of the period (see section 7.2.2 above). [IFRS 9.6.5.11(d)(i)].

A similar approach would equally apply to situations where a hedged forecast transaction involving a non-financial asset or non-financial liability subsequently becomes a firm commitment for which fair value hedge accounting is applied.

For any other cash flow hedges, the amount accumulated in equity is reclassified to profit or loss as a reclassification adjustment in the same period or periods during which the hedged cash flows affect profit or loss. This accounting entry does affect OCI for the period and must be disclosed as a reclassification adjustment in OCI. [IFRS 9.6.5.11(d), IAS 1.92, IFRS 18.90].

9.2 Fair value hedges

Entities recognise the gain or loss on the hedging instrument in profit or loss and adjust the carrying amount of the hedged item for the hedging gain or loss with the adjustment being recognised in profit or loss (see section 7.1.1 above).

For hedged items that are debt instruments measured at fair value through OCI in accordance with IFRS 9.4.1.2A (see Chapter 46), the gain or loss on the hedged item results in recognition of that amount in profit or loss rather than accumulating in OCI. This means fair value hedge accounting changes the presentation of gains or loss on the hedged item, but the measurement of the debt instrument at fair value remains unaffected. [IFRS 9.6.5.8(b)].

For hedged items that are equity instruments for which an entity has elected to present fair value changes in OCI without subsequent reclassification to profit or loss, the accounting for a fair value hedge is different because it does not affect profit or loss but, instead, OCI. There is no change to the accounting for the hedged item and the gain or loss on the hedging instrument is recognised in OCI (see sections 2.6.3, 7.1.1 and 7.8 above). [IFRS 9.6.5.8].

³² [IFRIC Update](#), March 2018, available on the IFRS Foundation’s website

9.3 Hedges of groups of items

9.3.1 Cash flow hedges

The designation of a group of items within a cash flow hedge, has no effect on the presentation in profit or loss of those designated hedged items. However, the presentation of the related hedging gains or losses in the statement of profit or loss depends on the nature of the group position. [IFRS 9.B6.6.13, IFRS 9.B6.6.14, IFRS 9.B6.6.15]. The required presentation for hedges of groups of items is discussed in more detail in Chapter 50 and is summarised in the table below.

Figure 9-1: Presentation for a hedge of groups of items

Nature of position	Line items affected in profit or loss	Presentation in the income statement
Gross position	One line item	The amount reclassified from equity to profit or loss has to be presented in the same line item as the underlying hedged transaction.
	Multiple line items	The amount reclassified from equity to profit or loss has to be allocated to the line items affected by the hedged items on a systematic and rational basis but shall not result in a gross up of the net gains or losses on the hedging instrument.
Net position	Multiple line items	The amount reclassified from equity to profit or loss has to be presented in a separate line item.

Note that the designation of a net position cash flow hedge is only permitted when hedging foreign currency risk (see section 2.5.3 above).

For net position cash flow hedges, as the hedging gains and losses will be presented in a different line to that in which the hedged items are presented in profit or loss, such a hedge designation might not seem very attractive, as the presentation of the hedged transactions will not reflect the effect of the hedge. However, the Board was concerned that grossing-up the hedging gain or loss would result in non-existing gains or losses being recognised in the statement of profit or loss, which would be in conflict with general accounting principles. [IFRS 9.BC6.457, IFRS 9.BC6.458]. The Board also considered that such a presentation makes it transparent that an entity is hedging on a net basis and would clearly present the effect of those hedges of net positions on the face of the statement of profit or loss. [IFRS 9.BC6.461]. However, because of this presentation, in practice some entities might choose to continue to designate a proportion of a gross position rather than a net designation. Such a 'proxy designation' would be permitted provided the designation is directionally consistent with the actual risk management activities (see section 6.2.1 above). [IFRS 9.BC6.98, IFRS 9.BC6.100(a)].

9.3.2 Fair value hedges

A special presentation in the income statement is prescribed for fair value hedges of groups of items with offsetting risk positions (i.e., hedges of a net position), whose hedged risk affects different profit or loss line items. Entities must present the hedging gains or losses of such a hedge in a separate line item in the income statement in order to avoid grossing up the hedging gain or loss on a single instrument into multiple line items. Hence in that situation the amount in the line item that relates to the hedged item itself remains unaffected. [IFRS 9.6.6.4, IFRS 9.B6.6.16].

However, the treatment in the statement of financial position is different, in that the individual items in the group are separately adjusted for the change in fair value due to changes in the hedged risk. [IFRS 9.6.6.5].

9.4 Costs of hedging

When applying the costs of hedging accounting to the time value of an option contract, the forward element of a forward contract or the foreign currency basis spread of a financial instrument, the treatment for the amount accumulated in a separate component of equity is dependent on the nature of the underlying hedged item (see section 7.5 above).

For transaction related hedges:

- If the hedged item subsequently results in the recognition of a non-financial asset or liability, or a firm commitment for a non-financial asset or liability for which fair value hedging will be applied, the amount accumulated in a separate component of equity is removed from equity and included directly in the carrying amount of the asset or liability. This is not a reclassification adjustment, and so does not affect the statement of OCI of the period. Rather, it is presented as a separate item in the statement of changes in equity.
- For other transaction related hedging relationships (such as a hedge of highly probable forecast sales), the amount accumulated in a separate component of equity is reclassified to profit or loss as a reclassification adjustment in the same period or periods during which the hedged expected future cash flows affect profit or loss. This is a reclassification adjustment, and so does affect OCI of the period.
- If all or a portion of the amount accumulated in a separate component of equity is not expected to be recovered, the amount that is not expected to be recovered is immediately reclassified into profit or loss (see section 7.2.1 above). This is a reclassification adjustment, and so does affect OCI of the period. *[IFRS 9.6.5.15(b)].*

For time-period related hedges, the costs of hedging at the date of designation as a hedging instrument is required to be amortised on a systematic and rational basis over the period during which the hedged item impacts profit or loss (see section 7.5.1 above). The 'costs of hedging' in this context is the time value of an option contract, the forward element of a forward contract or the foreign currency basis spread, to the extent that it relates to the hedged item, (see section 7.5.1.A above). However, if the hedge relationship is discontinued, the net amount remaining in OCI (i.e., including cumulative amortisation) is immediately reclassified into profit or loss. Both are reclassification adjustments, and so do affect OCI of the period. *[IFRS 9.6.5.15(c)].* The standard is however silent as to where in profit or loss the costs of hedging accumulated in OCI are to be recycled. Given the lack of explicit guidance, an accounting policy will need to be developed and applied consistently (see section 7.5.1 above).

10 Macro hedging

At a detailed level, the topic of portfolio (or macro) hedging for banks and similar financial institutions is beyond the scope of a general financial reporting publication such as this. However, no discussion of hedge accounting would be complete without an overview of the high level issues involved and an explanation of how the standard setters have tried to accommodate these entities.

Financial institutions, especially retail banks, usually have as a core business the collection of funds by depositors that are subsequently invested as loans to customers. This typically includes instruments such as current and savings accounts, deposits and borrowings, loans and mortgages that are usually accounted for at amortised cost. The difference between interest received and interest paid on these instruments (i.e., the net interest margin) is a main source of profitability.

A bank's net interest margin is exposed to changes in interest rates, a risk most banks (economically) hedge by entering into derivatives (mainly interest rate swaps). Applying the hedge accounting requirements as set out in IFRS 9 to such hedging strategies on an individual item-by-item basis can be difficult as a result of the characteristics of the underlying financial assets and liabilities:

- Prepayment options are common features of many fixed rate loans to customers (see sections 2.3.2 and 2.5.2 above). Customers exercise these options for many reasons, such as when they move house, and so not necessarily always in response to interest rate movements. Their behaviour can be predicted better on a portfolio basis rather than an item-by-item basis.
- As a result of the sheer number of financial instruments involved, banks typically apply their hedging strategies on a macro (or portfolio), dynamic basis, with the number of individual instruments in the hedged portfolio constantly changing.

In addition, not all exposures that form part of a bank's risk management of net interest margin are eligible as hedged items. For example, it is common for banks to attribute a 'deemed' fixed rate interest rate risk from their demand deposits, such as current account balances, savings accounts and other accounts paying either no or very low rates of interest, consistent with the bank's expectations as to how they will behave. These deemed fixed rate liabilities are often referred to as 'core demand deposits'. However, banks are prohibited by IFRS 9 from including core demand deposits in a manner that is consistent with their risk management strategy (see section 2.6.7 above). [IAS 39.F.2.3].

IAS 39 includes some specific guidance originally designed with macro hedging in mind. Currently some of this guidance can still be applied even when IFRS 9 is applied (see section 10.2 below). [IFRS 9.6.1.3]. The IAS 39 macro hedging guidance exists for portfolio fair value, [IAS 39.81A, IAS 39.89A, IAS 39.AG114 - 132], and cash flow hedge accounting, [IAS 39.F.6.1, IAS 39.F.6.2, IAS 39.F.6.3], for interest rate risk. However, banks did not always use the IAS 39 macro hedge accounting solutions. This is because not all sources of interest rate risk qualify for hedge accounting, the use of the IAS 39 solutions can be operationally complex and cash flow hedge solutions result in volatility of other comprehensive income. Some European banks, instead, made use of the European Union's carve out of certain sections of the IAS 39 hedge accounting rules (see Chapter 1).

The accounting for macro hedging was originally part of the IASB's project to replace IAS 39 with IFRS 9. However, the IASB realised that developing the new accounting model would take time and probably involve a different concept from hedge accounting. In May 2012, the Board therefore decided to decouple the part of the project related to the accounting for macro hedging from IFRS 9, allowing more time to develop an accounting model without affecting the timeline for the completion of the other elements of IFRS 9.³³ This separate project is referred to as Accounting for Dynamic Risk Management. The status of the project is discussed in section 10.1 below.

³³ [IASB Update](#), May 2012, available on the IFRS Foundation's website.

10.1 Accounting for dynamic risk management

10.1.1 DRM project background

In April 2014, the IASB issued the Discussion Paper - *Accounting for Dynamic Risk Management: a Portfolio Revaluation Approach to Macro Hedging*.³⁴ Most respondents supported the need for the project, but there was no consensus on a solution. Given the diversity in views, in July 2015 the IASB concluded that the insights that it had received from the comment letters and feedback so far did not enable it to develop proposals for an exposure draft. Accordingly, the IASB decided that the project should remain in the research programme, with the aim of publishing a second discussion paper, most likely with a new accounting model, without further developing the Portfolio Revaluation Approach to Macro Hedging.

Since November 2017, the IASB have been developing a new accounting model for the recognition and measurement for dynamic risk management (the DRM model). The IASB developed a model with the aim that it will enable investors to understand a company's dynamic risk management activities and to evaluate the effectiveness of those activities. Having developed the core aspects of the model, the IASB undertook outreach on the core DRM model to gather stakeholders' views prior to developing a consultation document. The outreach focused on whether the stakeholders felt the core DRM model would enable banks to better reflect their risk management strategies and activities in the financial statements. The outreach was undertaken between October 2020 and February 2021 and took the form of individual meetings with international banks that manage interest rate risk using dynamic management strategies.

The IASB discussed the feedback from the outreach at its April 2021 meeting. In principle, almost all participants supported the objective of the DRM model to better reflect interest rate risk management strategy and activities in the financial statements. However, many commented that some important refinements were necessary in order for the DRM model to meet its objective.

As a result of the outreach, the IASB decided to make some key refinements to the 'core areas' of DRM model, in order to respond to the concerns raised and key challenges identified in the outreach. Through the various IASB meetings since May 2021, the DRM model was further developed and at its meeting in May 2022, the IASB thought it had completed its deliberations on the outline of the proposed DRM hedge accounting model. The IASB then moved the project from its research programme to its standard-setting programme.

Since then, the IASB has made various additional important tentative decisions in their meetings, with the last in October 2024 on transition requirements and a request for permission to start due process for publication of an Exposure Draft.

We expect the IASB to issue an Exposure Draft on the DRM model in December 2025 (at time of writing). Given the DRM model is an entirely new accounting method and will result in a significant change to accounting for an entity's risk management activities, we expect the Exposure Draft to have an extended comment period of 240 days.

10.1.2 Main features of the DRM model

The DRM model does have some similarities to IFRS 9 hedge accounting, such as the need for designations, an expectation of the existence of an economic relationship, inclusion of only external derivatives, a focus on change in fair value and recognition of some ineffectiveness. But it is not IFRS 9 hedge accounting as we know it.

Although the project is known as the Dynamic Risk Management project, more recently the IASB has been referring to interest rate repricing risk management activities in relation to this project, rather than DRM. This does not reflect a change in scope but a more precise description of the type of risk management activities to which the model is expected to be relevant.

The objective for the DRM model is to better reflect an entity's interest rate repricing risk management activities in the financial statements. Where possible the approach is expected to be aligned with risk management practices. By way of example, actual measures of risk and risk limits used for risk management purposes are expected to be important inputs when applying the new DRM model. However, given the different information needs and purposes of risk management and financial accounting, it is not possible for any accounting model to be fully aligned with risk management.

³⁴ Discussion Paper [DP/2014/1](#), *Accounting for Dynamic Risk Management: a Portfolio Revaluation Approach to Macro Hedging*, IASB, April 2014. Available on the IFRS Foundation's website.

For those entities undertaking interest rate repricing risk management activities, application of the new DRM model is expected to be optional. However, similar to IFRS 9 hedge accounting, voluntary discontinuation will not be permitted.

Given the stated objective of the model is to reflect an entity's interest rate repricing risk management activities, the model does not solely focus on reducing variability in either fair value or cash flows within the portfolios under risk management. Rather, the model is expected to reflect the fact that interest rate repricing risk management activities could focus on reducing both variability in net interest income and in fair value of the portfolios under risk management.

We expect more exposures to be eligible for inclusion within the model than are currently permitted when applying IFRS 9 hedge accounting (or IAS 39), for example core demand deposits. Further, the model allows more flexibility to reflect behavioural expectations of exposures, consistent with risk management. However, not all exposures included within interest rate repricing risk management activities will be eligible for inclusion, notably equity instruments.

In order to apply the model, an entity will need to identify the eligible exposures within their interest rate repricing risk management activities and associated external derivatives. It must also be determined that an economic relationship exists between the designated derivatives and the interest rate repricing risk within the exposures. Further, the risk management objective for mitigating repricing risk must not result in an increase in repricing risk exposure.

A key element of the model is the recognition of a 'DRM adjustment' in the statement of financial position. The adjustment represents the extent to which the entity has achieved its objective in mitigating interest rate repricing risk with derivatives. The other side is recognised in profit or loss, providing an offset to the profit or loss from derivatives designated as part of the interest rate repricing risk management activities. Some ineffectiveness may still arise in profit or loss if an entity's risk management objective is not sufficiently met. The DRM adjustment is then amortised to profit or loss in the same period or periods during which the mitigated risk in the underlying portfolios affect profit or loss.

Consistent with the dynamic nature of interest rate repricing risk management activities, there is an expectation that frequent redesignations will occur when applying the model, but have only prospective impacts. Discontinuation is expected to be rare, and will only be permitted when an entity changes its risk management strategy.

One of the IASB's expected benefits of the model is to improve the operational efficiency of the current hedge accounting approaches applied to interest rate repricing risk management activities. Accordingly, there is no expectation of extensive tracking of when and how exposures were included within the model, but there will be a capacity test to ensure the DRM adjustment is not recognised at an amount higher than the expected benefit of reduced variability to be realised in the future.

The IASB tentatively decided that initial application of the model should be prospective and that on the date of initial application it will be permitted to discontinue existing IFRS 9 hedging relationships. It was also tentatively decided that an entity making the transition to the DRM model be permitted to prospectively revoke, at the date of initial application, the designation of financial assets or financial liabilities under the fair value option in IFRS 9. The entity would then be required to designate those financial assets and financial liabilities in a DRM model at that date.

Once the DRM model is effective, the IASB has indicated they may fully withdraw the option to apply the hedge accounting requirements of IAS 39. In that case, all entities still applying the hedge accounting requirements of IAS 39 accounting would be impacted, not just those undertaking interest rate repricing risk management. All such entities would need to carefully consider what their hedge accounting solution looks like going forward under IFRS 9.

As is normal with any new standard there will be various new disclosure requirements when applying the DRM model. These will include not only ongoing requirements but some specific to initial application of the model. Further information on the disclosures can be found in Chapter 50.

The application of the DRM model will be a significant change for banks and any other financial institutions undertaking eligible interest rate repricing risk management. Careful consideration of the ED, including operational complexities, will be essential. This is likely to involve extensive fieldwork testing of the proposed requirements to assess whether the application of the DRM model would achieve the IASB's objective of better reflecting the effects of an entity's risk management activities in its financial statements.

For further information on the status of the DRM project and a more detailed explanation of how the model is expected to work, see our existing publication *Applying IFRS: IASB continues to develop its DRM accounting model*,³⁵ and a helpful video *Introduction to IASB's Dynamic Risk Management project*.³⁶ Once the ED is issued we will continue to produce further publications on this topic.³⁷

10.2 Applying hedge accounting for macro hedging strategies under IFRS 9

Because of its pending project on an accounting model specifically tailored to macro hedging (see section 10.1 above), the IASB created a scope exception from the IFRS 9 hedging accounting requirements that allows entities to use the fair value hedge accounting for portfolio hedges of interest rate risk, and only for such hedges, as defined and set out in IAS 39. [IFRS 9.6.1.3]. However, once the new macro hedging or dynamic risk management (DRM) accounting model is effective, the IASB has indicated they may fully withdraw the option to apply the hedge accounting requirements of IAS 39. The specific guidance that defines what is meant by the fair value hedge accounting for portfolios of interest rate risk is set out in IAS 39.81A and 89A and IAS 39.AG114 to AG132. The application of this guidance for banks and similar financial institutions is beyond the scope of a general financial reporting publication such as this and so is not covered further within this publication.

However, IFRS 9 does not include a similar scope exception for the 'macro' cash flow hedge accounting set out in the Implementation Guidance to IAS 39, often applied by financial institutions to interest rate positions for which interest rate risk is managed on a net basis. [IAS 39.F.6.1, IAS 39.F.6.2, IAS 39.F.6.3]. The IASB is of the view that as the macro cash flow hedge accounting model is an application of the general hedge accounting model under IAS 39, the macro cash flow hedge accounting model could remain an application of the IFRS 9 hedge accounting guidance. Accordingly, the IASB did not want to make an exception for the macro cash flow hedge accounting approach and so decided to retain an earlier decision not to carry forward to IFRS 9 any IAS 39 Implementation Guidance on hedge accounting. [IFRS 9.BC6.95].

However, many financial institutions were concerned that their understanding of the IAS 39 macro cash flow hedge accounting model was not totally consistent with IFRS 9 and that they would not be able to continue with their existing macro cash flow hedging strategies under IFRS 9.

Eventually, the IASB gave entities the following choices until the project on accounting for macro hedging is completed:

- To apply the hedge accounting requirements as set out in IFRS 9, in full.
- To apply the hedge accounting requirements as set out in IFRS 9 to all hedges except fair value hedges of the interest rate exposure of a portfolio of financial assets or financial liabilities; in that case an entity must also apply the paragraphs that were added to IAS 39 when that particular type of hedge was introduced (IAS 39.81A and 89A and IAS 39.AG114 to AG132) - i.e., an entity must apply all the hedge accounting requirements of IAS 39 (including the 80%-125% bright line effectiveness test as well) including the paragraphs that specifically address fair value hedges of the interest rate exposure of a portfolio of financial assets or financial liabilities; the choice to apply IAS 39 in these situations is the result of the scope of the hedge accounting requirements of IFRS 9 and available on a case-by-case basis (i.e., it is not an accounting policy choice). [IFRS 9.6.1.3].

Or

- To continue applying hedge accounting as set out in IAS 39 to all hedges until the project on accounting for macro hedging is completed; this is an accounting policy choice. [IFRS 9.7.2.21]. Because it is an accounting policy choice, an entity might later change its policy and start applying the hedge accounting requirements of IFRS 9 (subject to the transition requirements of IFRS 9 for hedge accounting) (see section 12.1 below). However, even if an entity chooses to continue to apply the hedge accounting requirements of IAS 39, the entity still must provide the hedge accounting disclosures that were developed during the IFRS 9 project because those disclosure requirements have become a part of IFRS 7 for which no similar accounting policy choice to continue to apply the previous requirements was provided. [IFRS 9.BC6.104]. Once an entity changes its accounting policy and starts to apply the hedge accounting requirements of IFRS 9, it cannot go back to applying IAS 39 (see section 12.1 below).

11 Alternatives to hedge accounting

11.1 Fair value option for credit risk exposures

Many financial institutions hedge the credit risk arising from loans or loan commitments using credit default swaps (CDS). This would often result in an accounting mismatch, as loans and loan commitments are typically not accounted for at fair value through profit or loss, whereas the CDSs would be. The most natural approach to hedge accounting would be to designate the credit risk as a risk component in a hedging relationship. However, the IASB noted that due to the difficulty in isolating the credit risk as a separate risk it does not meet the eligibility criteria for risk components (see section 2.2.1 above). As a result, the accounting mismatch creates profit or loss volatility. [IFRS 9.BC6.470]. The Exposure Draft leading up to IFRS 9 did not propose any changes in this area, however, the IASB asked its constituents to comment on three alternative approaches, none of which were that credit risk could be deemed an eligible risk component for hedge accounting. The feedback from constituents showed that accounting for credit risk hedging strategies is a major concern for many financial institutions. [IFRS 9.BC6.491].

In its redeliberations the Board reconfirmed its view that credit risk does not qualify as a separate risk component for hedge accounting purposes. [IFRS 9.BC6.504]. However, the IASB decided that an entity undertaking economic credit risk hedging may, at any time, elect to account for all or a proportion of a debt instrument (such as a loan or a bond), a loan commitment or a financial guarantee contract, to the extent that any of these instruments is managed for changes in its credit risk, at fair value through profit or loss. This was one of the alternative approaches set out in the Exposure Draft. This election can only be made if the asset referenced by the credit derivative has the same issuer and subordination as the hedged exposure (i.e., both the issuer's name and seniority of the exposure match). The accounting for the credit derivative would not change, i.e., it would continue to be recorded at fair value through profit or loss. [IFRS 9.6.7.1].

If the election is made, the difference at that time between the carrying value (if any) and the fair value of the financial instrument designated as at fair value through profit or loss is immediately recognised in profit or loss. In the case of a debt instrument accounted for as at fair value through other comprehensive income, the carrying amount (i.e., fair value) does not change but instead the gain or loss that has been accumulated in the revaluation reserve has to be reclassified to profit or loss, as a reclassification adjustment. [IFRS 9.6.7.2]. Different to a fair value hedge, once elected, the financial instruments hedged for credit risk are measured at their full fair value instead of just being adjusted for changes in the risk actually hedged. As a result, by economically hedging the credit risk exposure and applying the fair value option consistent with the guidance in IFRS 9.6.7.1, the entity also has to revalue the financial instrument for changes in interest rates, which could result in profit or loss volatility.

An entity must discontinue the specific accounting for credit risk hedges in line with its actual risk management. This would be the case when the credit risk either no longer exists or if the credit risk is no longer managed using credit derivatives (irrespective of whether the credit derivative still exists or is sold, terminated or settled). [IFRS 9.6.7.3].

On discontinuation, the accounting for the financial instrument reverts to the same measurement category that had applied before the designation as at fair value through profit or loss. However, the fair value of the financial instrument on the date of discontinuing the accounting at fair value through profit or loss becomes the new carrying amount on that date. [IFRS 9.6.7.4]. For example, the fair value of a loan at the time of discontinuation becomes its new deemed amortised cost, which is also the basis to determine its new effective interest rate. This applies also to a debt instrument that reverts to accounting at fair value through other comprehensive income because it is required to affect profit or loss in the same way as a financial instrument at amortised cost. [IFRS 9.5.7.11]. This means the revaluation reserve only includes the gains and losses that arise after the date on which the accounting at fair value through profit or loss ceased.

For a loan commitment or a financial guarantee contract, the fair value at the date on which the accounting at fair value through profit or loss ceased is amortised over the remaining life of the instrument in accordance with the principles of IFRS 15 *Revenue from Contracts with Customers* unless the impairment requirements of IFRS 9 would require a higher amount than the remaining unamortised balance (see Chapter 46). [IFRS 9.4.2.1].

In contrast to the fair value option under IFRS 9 (see Chapter 44), the possibility to elect to measure at fair value through profit or loss those financial instruments whose credit risk is managed using credit derivatives, has the following advantages:

- The election can be made after initial recognition of the financial instrument
 - The election is available for a proportion of the instrument (instead of only the whole instrument)
- And
- The fair value through profit or loss accounting can be discontinued if credit risk hedging no longer occurs

Consequently, even though it is not an equivalent to fair value hedge accounting, this accounting does address several, but not all, concerns of entities that use CDSs for hedging credit exposures.

If credit exposures are designated as measured at fair value through profit or loss additional disclosure requirements apply (see Chapter 50). [IFRS 7.24G].

11.2 Fair value option for own use contracts

Contracts accounted for in accordance with IFRS 9 include those contracts to buy or sell non-financial items that can be settled net in cash, as if they were financial instruments (i.e., they are in substance similar to financial derivatives). Many commodity purchase and sale contracts meet the criteria for net settlement in cash because the commodities are readily convertible to cash. However, such contracts are excluded from the scope of IFRS 9 if they were entered into and continue to be held for the purpose of the receipt or delivery of a non-financial item in accordance with the entity's expected purchase, sale or usage requirements. [IFRS 9.2.4]. This is commonly referred to as the 'own use' scope exception. Own use contracts are further discussed in Chapter 41.

Own use contracts are accounted for as normal sales or purchase contracts (i.e., executory contracts), with the idea that any fair value change of the contract is not relevant given the contract is used for the entity's own use. However, some entities in certain industries enter into contracts for own use and similar financial derivatives for risk management purposes and manage all these contracts together. In such a situation, own use accounting leads to an accounting mismatch as the fair value change of the derivative positions used for risk management purposes cannot be offset against fair value changes of the own use contracts.

To eliminate the accounting mismatch, an entity could apply hedge accounting by designating an own use contract as the hedged item in a fair value hedging relationship. However, hedge accounting in these circumstances is administratively burdensome. Furthermore, entities often enter into large volumes of commodity contracts and, within the large volume of contracts, some positions might offset each other. An entity would therefore typically hedge on a net basis.

To address this issue, IFRS 9 includes a fair value option for own use contracts. At inception of a contract, an entity may make an irrevocable designation to measure an own use contract at fair value through profit or loss (the 'fair value option'). However, such designation is only allowed if it eliminates or significantly reduces an accounting mismatch. [IFRS 9.2.5].

Illustration 11-1: Processing and brokerage of soybeans and sunflowers

An entity is in the business of procuring, transporting, storing, processing and merchandising soybeans and sunflower seeds. The inputs and the outputs are agricultural commodities which are traded in liquid markets. The entity has both a broker business and a processing business, which are operationally distinct. However, the entity analyses and monitors its net commodity risk position, comprising inventories, physically settled forward purchase and sales contracts and exchange traded futures and options. The target is to keep the net fair value risk position close to nil.

Applying the guidance in IFRS 9.2.4, the physically settled forward contracts from the processing business have to be accounted for as own use contracts, whereas all other contracts are accounted for at fair value through profit or loss. The resulting accounting mismatch does not reflect how the entity is managing the overall fair value risk of those contracts.

If the entity applied the fair value option to the physically settled contracts, this would eliminate the accounting mismatch.

Some entities, especially in the power and utilities sector, enter into long-term own use contracts, sometimes for as long as 15 years. The business model of those entities would often be to manage those contracts together with other contracts on a fair value basis. However, there are often no derivatives available with such long maturities, while fair values for longer dated contracts could be difficult to determine. Hence, for risk management purposes a fair value based approach might only be used for the time horizon in which derivatives are available, i.e., sometime after inception of the contract. The fair value option is, however, only available on inception of the own use contract. As risk management of longer term own use contracts on a fair value basis usually occurs sometime after inception of the contract, the fair value option will mainly be useful for shorter-term own use contracts.

12 Effective date and transition

12.1 Effective date

IFRS 9 was effective for periods beginning on or after 1 January 2018 and replaced substantially all of IAS 39, including the hedge accounting requirements. However, as stated in sections 1.3 and 10.1 above, an entity has the accounting policy choice to continue applying hedge accounting as set out in IAS 39 to all hedges until the project on accounting for macro hedging is completed, instead of the requirements of Chapter 6 of IFRS 9. [IFRS 9.7.2.21].

How we see it

We believe that an entity can choose to adopt the IFRS 9 hedge accounting requirements subsequent to the initial adoption of IFRS 9, as there is nothing in the transition guidance that indicates that an entity must continue to apply the accounting policy choice until the macro hedging project is finished. Adoption of IFRS 9 hedge accounting can only start from the beginning of a reporting period, and although not explicit in the standard, we believe that the reporting period can be an annual reporting period or an interim reporting period. However, it is not possible to switch back to the hedge accounting provisions of IAS 39 once Chapter 6 of IFRS 9 has been applied.

The IFRS 9 transition guidance is applicable when an entity first applies the requirements of the standard, and it is noted that more than one date of initial application could arise for the different requirements of IFRS 9. [IFRS 9.7.2.2]. Hence, we believe the transition guidance for IFRS 9 hedge accounting (Chapter 6), as described in IFRS 9.7.2.21 to 7.2.26, is applicable when an entity changes its accounting policy to apply IFRS 9 hedge accounting subsequent to the initial adoption of IFRS 9. However, for first time adopters of IFRS accounting standards, the transition guidance in IFRS 9 is not relevant, and hence the accounting policy choice to apply the hedge accounting requirements of IAS 39 is not available. Even if applying IFRS accounting standards for the first time, for a fair value hedge of the interest rate exposure of a portfolio of financial assets or financial liabilities (and only for such a hedge), an entity may apply the related hedge accounting requirements in IAS 39 instead of those in IFRS 9 (see section 1.3 above). [IFRS 9.6.1.3].

It should also be noted that on subsequent adoption of IFRS 9 hedge accounting, comparatives will need to be restated for any retrospective application (albeit retrospective application is limited (see sections 12.2 and 12.3 below)). The transition guidance that permitted entities not to restate comparatives was only relevant on adoption of the classification and measurement requirements of IFRS 9. [IFRS 9.7.2.15].

The accounting policy choice to continue to apply the hedge accounting requirements of IAS 39, effectively defers all of Chapter 6 of IFRS 9, (although not the IFRS 7 disclosure requirements on hedge accounting introduced by IFRS 9 (see Chapter 50)). As the guidance on designating credit exposures at fair value through profit or loss (see section 11.1 above) is included within Chapter 6 of IFRS 9, it cannot be applied if an entity chooses to remain on IAS 39 for hedge accounting.

Furthermore, if an entity has an equity instrument classified at fair value through other comprehensive income as permitted by IFRS 9.5.7.5 and has chosen to continue to apply the IAS 39 hedge accounting requirements; we believe that such an equity instrument is not an eligible hedged item as it will not impact profit or loss (see section 13.2 below). [IAS 39.86]. This is because the specific guidance in IFRS 9.6.5.8 which permits designation of an equity instrument for which an entity has elected to present changes in fair value in other comprehensive income in a fair value hedge is not applicable if the entity remains on IAS 39 hedge accounting (see section 2.6.3 above and section 13.2 below).

12.2 Prospective application in general

A hedging relationship can only be designated on a prospective basis, in order to avoid the use of hindsight. The same concern about using hindsight would also apply if the IFRS 9 hedge accounting requirements were to be applied retrospectively. Consequently, the IASB decided that hedge accounting in accordance with IFRS 9 has to be applied prospectively, with some limited exceptions. [IFRS 9.7.2.22]. Because the date of initial application can only be the beginning of a reporting period, an entity can only start applying the hedge accounting requirements of IFRS 9 prospectively from the beginning of a reporting period, and only if all qualifying criteria - including the hedge accounting documentation that conforms to IFRS 9 are met on that date. [IFRS 9.7.2.2, IFRS 9.7.2.23].

When transitioning from applying hedge accounting under IAS 39 to IFRS 9, the standard clarifies that hedging relationships under IAS 39 which also qualify for hedge accounting under IFRS 9, are treated as continuing hedging relationships. [IFRS 9.7.2.24]. Hedge accounting under IAS 39 ceases in the very same second as hedge accounting under IFRS 9 starts, therefore resulting in no accounting entries on transition. However, entities might have to rebalance their hedges on transition to fulfil the effectiveness requirements under IFRS 9 (see sections 6.4.3 and 8.2 above) in which case any resulting gain or loss must be recognised in profit or loss. [IFRS 9.7.2.25].

Entities will need to ensure the existing IAS 39 hedge documentation is updated to meet the requirements of IFRS 9 on the date of initial application (see section 6.3 above). As a minimum this would include the following:

- Reconsideration of the documented risk management strategy and objective
 - The approach and rationale for concluding the eligibility criteria are met, specifically an explanation of the economic relationship, the effect of credit risk, and the hedge ratio
 - Identification of all major sources of ineffectiveness
 - Justification for designation of any risk components
 - Deletion of the retrospective effectiveness assessment
- And
- The approach to costs of hedging (if applicable)

12.3 Limited retrospective application

The exceptions from prospective application of IFRS 9 are for the accounting treatment for the time value of options, when only the intrinsic value is designated; and, at the option of the entity, for the forward element of forward contracts, when only the spot element is designated, and the foreign currency basis spread of financial instruments (see section 7.5 above). However, retrospective application shall not be applied to items that have already been derecognised at the date of application. [IFRS 9.7.2.1, IFRS 9.7.2.26].

12.3.1 Accounting for the time value of options

Entities must apply the new accounting treatment for the time value of options retrospectively, if in accordance with IAS 39, only the hedging option's intrinsic value was designated as part of the hedge relationship (see section 13.6 below). However, retrospective treatment is only applied to hedging relationships that existed at the beginning of the earliest comparative period and hedging relationships designated thereafter. [IFRS 9.7.2.26(a), IFRS 9.BC7.49].

How we see it

We believe that in order for a hedge relationship to 'exist' as at the beginning of the earliest comparative period, it must have met all the hedge accounting conditions in IAS 39.88 on that date, including demonstration of effectiveness (see section 13 below).

There is also the restriction that IFRS 9 shall only be applied to items that have not been derecognised by the date of application, which would preclude any retrospective application to hedge relationships for which either of the hedging instrument or hedged item have been derecognised prior to that date. [IFRS 9.7.2.1].

For those foreign entities registered with and reporting to the United States Securities and Exchange Commission and required to present two comparative years of income statements, this means they would have a longer period to adjust for the retrospective application of the new requirements.

Applying the new accounting requirement retrospectively might have a much wider impact on comparative periods than is at first apparent. Depending on the type of hedging relationship, many line items in the primary statements and many disclosures in the notes could be affected.

Illustration 12-1: Retrospective application of accounting for time value of option

An entity applies the IFRS 9 hedge accounting requirements for the first time in its accounting period beginning 1 September 20X2 and 1 September 20X1 is the beginning of its earliest comparative period presented.

As of 1 September 20X2, the entity had a hedging relationship in place in which the intrinsic value of an option was designated as the hedging instrument of the foreign currency risk of a highly probable forecast purchase of a machine on 30 November 20X2. For the purposes of this example, there is an assumption that no sources of ineffectiveness exist. When preparing the August 20X3 financial statements, the entity would have to:

- Determine the change in the time value of that option as of 1 September 20X1 and restate accumulated other comprehensive income (OCI) against retained earnings as of that date
 - Determine the change in time value of that option from 1 September 20X1 to 31 August 20X2 and restate accumulated OCI against retained earnings as of that date
 - Reflect the restatement in the statement of profit or loss and OCI and the statement of changes in equity for the comparative period
- And
- Reflect the restatement in the notes disclosures

12.3.2 Accounting for the forward element of forward contracts

Different to the accounting for the time value of options, entities have a choice of whether or not to apply retrospectively the new costs of hedging accounting for the forward element of forward contracts (see section 7.5.2 above). This is exclusively relevant for hedge relationships where, in accordance with IAS 39, only changes in the spot element of a hedging forward contract were designated within the hedge relationship. The choice applies on an all or nothing basis (i.e., if an entity elects to apply the accounting retrospectively, it must be applied to all hedging relationships that qualify for the election). The retrospective application would also only apply to those hedging relationships that 'existed' at the beginning of the earliest comparative period or that were designated thereafter (see section 12.3.1 above).

[IFRS 9.7.2.26(b), IFRS 9.BC7.49]. Assets and liabilities cannot be adjusted to reflect hedges that had already finished at the start of the comparative period.

How we see it

If under IAS 39 the forward rate was designated in a hedge relationship (i.e., no portions are excluded from the hedging instrument (see section 3.6.5 above)), yet on application of IFRS 9 designation of only the spot rate is deemed preferable, we believe that such a change to the designation must be treated as discontinuation of the original relationship and the re-designation of a new relationship, hence the retrospective application for accounting for the forward element under IFRS 9 will not apply. In that case, see section 12.3.4 below.

12.3.3 Accounting for foreign currency basis spread

Similar to the retrospective transition guidance for the accounting for the forward element of forward contracts, it is also possible to apply retrospectively the accounting for foreign currency basis spreads (see in section 7.5.3 above) on transition to IFRS 9 hedge accounting. However, in contrast to the transition requirements for the forward element of forward contracts, the decision to apply retrospectively the costs of hedging guidance on foreign currency basis spreads can be made on a hedge-by-hedge basis, without a requirement that foreign currency basis had been excluded from the designation under IAS 39. This is owing to the differences in circumstances: IAS 39 did not have an exception for excluding a foreign currency basis spread from the designation of a financial instrument as a hedging instrument. The hedge-by-hedge choice can be made for those hedging relationships that 'existed' at the beginning of the earliest comparative period or that were designated thereafter (see section 12.3.1 above). [IFRS 9.7.2.26(b), IFRS 9.BC7.49].

12.3.4 Re-designation of hedge relationships for non-financial risk components

IFRS 9 permits the designation of eligible risk components in non-financial hedged items (see section 2.2 above). Such a designation was not possible under IAS 39. This means, even if entities were economically hedging a risk component, they were obliged to designate the change in the entire hedged item as the hedged risk in order to achieve hedge accounting. Such a designation was likely to result in the recognition of ineffectiveness in profit or loss and in some cases failure of the effectiveness requirements.

On transition to IFRS 9 hedge accounting, entities might wish to amend hedge accounting relationships such that the hedged risk is an eligible risk component for non-financial hedged items. The question is whether that change in the documented hedged risk must result in the discontinuation of the original hedge relationship and the start of a new hedge relationship, or whether it can be treated as an amendment to the original designation such that the original hedge relationship continues. This question is particularly relevant for cash flow hedges, as on re-designation the non-zero fair value of the hedging instrument can result in subsequent ineffectiveness recorded in profit or loss (see section 7.4.3 above).

How we see it

We believe that a change in the documented hedged risk from the 'entire change in hedged item' to a risk component must be treated as a discontinuation of the original hedge relationship and the re-designation of a new hedge relationship, because it can be seen as either a change in the hedged item or a change in the documented risk management objective which both require discontinuation of a hedging relationship (see section 8.3 above).

The IASB was nervous of permitting any retrospective application of the IFRS 9 hedge accounting requirements, as such an application could involve the use of hindsight, for example as to whether it is beneficial or not to change the hedged risk to be an eligible risk component. The specific scenarios where retrospective application is permitted are generally those that either do not involve the use of hindsight as IFRS 9 application relied on particular choices that had already been made under IAS 39 (e.g., the designation of the intrinsic value of an option or the spot element of a forward). [IFRS 9.BC7.48, IFRS 9.BC7.49]. Due to the absence of a specific respective transition relief, it follows that a hedge relationship cannot continue if an eligible risk component under IFRS 9 is introduced into an existing IAS 39 hedge relationship. The question has been asked as to whether this transition issue could be resolved by 'dual-designating' the hedge relationship, at the inception of the hedge, under both IAS 39 and IFRS 9. The IAS 39 designation would be for the full price risk, while the IFRS 9 designation would be of just the eligible risk component. Unfortunately, this does not work, because the switch from the IAS 39 hedge designation to the IFRS 9 hedge designation would reflect a change in risk management objective, which would result in discontinuation of the first hedge relationship (see section 8.3 above).

The logical follow-on question is whether an entity can continue with the original IAS 39 designation although it does not exactly represent the entity's risk management objective. We note that although the objective of hedge accounting under IFRS 9 is to represent an entity's risk management activities, [IFRS 9.6.1.1], it does not require that it is an exact match. The Basis for Conclusions notes that, in some circumstances, the designation for hedge accounting purposes is inevitably not the same as an entity's risk management view of its hedging, but that the designation reflects risk management in that it relates to the same type of risk that is being managed and the instruments used for this purpose. The IASB refer to this situation as 'proxy hedging', which is an eligible way of designating the hedged item under IFRS 9 provided that it still reflects risk management (see section 6.2.1 above). One example of proxy hedging mentioned is those instances where the risk management objective is to hedge a risk component, but the accounting hedge designation is for the full price risk. [IFRS 9.BC6.100(b)].

Where there is a choice of accounting hedge designation, there is no requirement for an entity to select the designation that most closely matches the risk management view of hedging as long as the chosen approach still reflects risk management. [IFRS 9.BC6.97, IFRS 9.BC6.98]. Consequently, it is permitted, on transition, to continue with an accounting designation of the full price risk even if the management objective was always to hedge a component of risk, provided all the other qualifying criteria are met (see section 6.1 above).

Both questions above were debated by the IFRS IC in September 2015 and January 2016. The final agenda decision reached by the IFRS IC is consistent with the analysis presented above.³⁸

³⁸ [IFRIC Update](#), January 2016, available on the IFRS Foundation's website.

13 Main differences between the IFRS 9 and IAS 39 hedge accounting requirements

Most of the basics of hedge accounting are the same under both IFRS 9 and IAS 39, however there are some significant differences. We discuss the main differences between IFRS 9 and IAS 39 hedge accounting below.

IAS 39 includes some specific guidance originally designed with portfolio fair value hedges of interest rate risk. Equivalent guidance does not appear in IFRS 9, but entities applying hedge accounting under IFRS accounting standards may continue to apply the IAS 39 guidance on this topic - see section 10 above for further details.

IAS 39 includes extensive Implementation Guidance on the application of hedge accounting. In developing IFRS 9, the IASB decided not to carry forward any of the hedge accounting related Implementation Guidance that accompanied IAS 39. However, the IASB emphasised that not carrying forward the Implementation Guidance did not mean that it had rejected the guidance for the application of IFRS 9. [IFRS 9.BC6.93, IFRS 9.BC6.94, IFRS 9.BC6.95]. Much, but not all, of the Implementation Guidance in IAS 39 therefore remains relevant on application of IFRS 9 (see section 1.3 above).

13.1 The objective of hedge accounting

The objective of IFRS 9 hedge accounting is to represent in the financial statements, the effect of an entity's risk management activities that use instruments to manage exposures arising from particular risks that could affect profit or loss (or OCI in the case of equity investment designated at FVOCI). This approach aims to convey the context of hedging instruments for which hedge accounting is applied in order to provide insight into their purpose and effect. [IFRS 9.6.1.1]. There is no such objective within IAS 39.

The perceived purpose of hedge accounting under IAS 39 is to reduce the accounting mismatches caused by risk management activity, but it has no conceptual objective. Consequently, it is a more rules-based standard, which is particularly evident in the 80-125% quantitative threshold for the retrospective hedge effectiveness assessment (see section 13.4 below).

Similar to IFRS 9, IAS 39 includes a requirement to document the risk management strategy and risk management objective for undertaking the hedge (see section 6.2 above). [IAS 39.88(a)]. However, whereas, under IFRS 9, the risk management objective is rooted in risk management practice and determines whether the hedge relationship can be or must be discontinued, under IAS 39 it is just part of the accounting designation.

13.2 Eligible hedged items

The hedge accounting guidance under IAS 39 has a number of additional restrictions on the eligibility of hedged items that do not appear within the IFRS 9 guidance. Most important is the preclusion of designating any risk components in non-financial hedged items, other than foreign currency risk. The rationale at the time was the difficulty of isolating and measuring the appropriate portion of cash flows or fair value changes attributable to specific risks (other than foreign currency risks) in a non-financial asset or liability. [IAS 39.82, IAS 39.AG100]. This preclusion has been removed in IFRS 9 (see section 2.2 above).

The ability to designate an aggregated exposure, which includes a derivative as the hedged item in a second hedging relationship is not possible under IAS 39 (see section 2.7 above). In order to achieve hedge accounting for the hedging instrument in the 'second hedge relationship', under IAS 39 the first hedge relationship would need to be de-designated and a new hedge relationship with a combined hedging instrument (i.e., the hedging instrument from the first and second hedge relationship) would need to be designated. The combined hedging derivative is likely to have a non-zero fair value which could result in additional ineffectiveness for a cash flow hedge (see section 7.4.3 above).

In addition, IAS 39 includes a complete prohibition on designating inflation as a risk component unless there is a contractually specified inflation portion, which is a harsher position than in IFRS 9 (see section 2.2.6 above). [IAS 39.AG99F].

IAS 39 permits designation of groups of hedged items, however the designation of a net position is prohibited under IAS 39, only gross designations are allowed. [IAS 39.84]. In addition, groups of hedged items are only eligible for designation under IAS 39 if the change in fair value attributable to the hedged risk for each individual item in the group is expected to be approximately proportional to the overall change in fair value attributable to the hedged risk of the group of items. [IAS 39.83]. This requirement does not form part of IFRS 9 hedge accounting (see section 2.5 above).

Although a hedge of a component of a nominal amount is permitted under IAS 39, the type of eligible component is more restrictive than under IFRS 9 (see section 2.3 above). For example, it is not possible to designate a layer of a hedged item in a fair value hedge under IAS 39. In order to achieve hedge accounting, designation of a proportion or specific cash flows within the hedged item would be required.

IFRS 9 includes an exception to the requirement that hedges could affect profit or loss, that is when an entity is hedging an investment in equity instruments for which it has elected to present changes in fair value in OCI (see section 2.6.3 above and Chapter 44). [IFRS 9.6.5.3]. No such exception exists under IAS 39, hence hedge accounting is precluded for equity investments for which the entity has elected to present changes in fair value in OCI. [IAS 39.86].

13.3 Eligible hedging instruments

Under IFRS 9 it is possible to designate, as hedging instruments, non-derivative financial assets or non-derivative financial liabilities that are accounted for at fair value through profit or loss (except for financial liabilities designated at fair value through profit or loss for which the amount of its change in fair value that is attributable to changes in the credit risk of that liability is presented in other comprehensive income) (see section 3.3 above). [IFRS 9.6.2.2]. However, this is not possible under IAS 39. It was previously possible only to designate a non-derivative financial instrument as the hedging instrument for a hedge of foreign currency risk, which is of course still permitted under IFRS 9 (see section 3.3.1 above). [IAS 39.72].

Similar to IFRS 9, a standalone written option is prohibited from qualifying as a hedging instrument under IAS 39, unless it is as an offset to a purchased option, including one that is embedded in another financial instrument (see section 3.2.2 above). However, IAS 39 does not allow standalone written options to be designated within a combination of other hedging derivatives, even if the combination of all the derivatives is not a net written option. [IAS 39.72].

13.4 Effectiveness criteria

Perhaps the most significant difference between IAS 39 and IFRS 9 are the criteria as to whether a hedge relationship is eligible for hedge accounting or not. Whilst IFRS 9 takes a principle-based approach (see sections 6.4 and 13.1 above), the eligibility criteria under IAS 39 are more rules-based. In particular, IAS 39 requires that:

- The entity expects the hedge to be highly effective in achieving offsetting changes in fair value or cash flows attributable to the hedged risk, consistent with the originally documented risk management strategy for that particular hedging relationship.
- The hedge must be assessed on an ongoing basis and determined actually to have been highly effective throughout the financial reporting periods for which the hedge was designated. [IAS 39.88].
- A hedge is regarded as highly effective only if both of the following conditions are met:
 - (i) At the inception of the hedge, and in subsequent periods, the hedge is expected to be highly effective in achieving offsetting changes in fair value or cash flows attributable to the hedged risk during the period for which the hedge is designated.

And

- (ii) The actual results of the hedge are within a range of 80% to 125%.

For example, if actual results are such that the loss on the hedging instrument is LC120 and the gain on the cash instrument is LC100, offset can be measured by $120 \div 100$, which is 120%, or by $100 \div 120$, which is 83%. In this example, assuming the hedge meets the condition in (i), it would be concluded that the hedge has been highly effective. [IAS 39.AG105].

It can be seen that IAS 39 requires that hedge relationships pass both a retrospective and prospective effectiveness test in order to achieve hedge accounting. The test itself is more restrictive, as it includes the requirement to achieve an arbitrary 80%-125% level of offset. The IFRS 9 effectiveness requirements are only forward looking, will normally be qualitative and permit judgement as to whether the requirements are met (see sections 6.4 and 8 above). Hence many more hedge relationships are precluded from hedge accounting under the stricter IAS 39 effectiveness tests. However, the requirement to measure and record any ineffectiveness is consistent under both IFRS 9 and IAS 39 (see section 7.4 above). [IAS 39.89, IAS 39.96].

13.5 Discontinuation

There is significant overlap in the guidance on discontinuation of hedge accounting under IAS 39 and IFRS 9, however there are some important differences. Whilst discontinuation of a hedge relationship is only permitted under IFRS 9 if one of the mandatory discontinuation criteria occur (see section 8.3 above), there is no prohibition on voluntary discontinuation of designated hedge relationships under IAS 39. An entity can just choose to prospectively stop hedge accounting. [IAS 39.91(c), IAS 39.101(d)].

If the IAS 39 effectiveness test is failed (see section 13.4 above), then the hedge relationship must be discontinued and hedge accounting ceases from the last time the hedge relationship was effective. Under IAS 39 there is no opportunity to amend the method of assessing effectiveness, rebalance the hedge relationship, or undertake a partial discontinuation (see sections 6.3, 8.2 and 8.3 above). [IAS 39.F.4.4, IAS 39.91(b), IAS 39.101(b)]. In addition, under IFRS 9, if discontinuation is required, this is only applied prospectively (see section 8.3 above).

The risk management objective plays a much more important role within IFRS 9 hedge accounting than under IAS 39 (see section 13.1 above). For example, there is no requirement to monitor whether the risk management objective has changed under IAS 39, as such a change is not one of the mandatory discontinuation criteria as it is under IFRS 9 (see section 8.3 above).

13.6 Hedge accounting mechanisms

The basic IAS 39 hedge accounting mechanics are the same as those under IFRS 9 (see section 7 above). However, IFRS 9 contains some accounting mechanisms that do not appear within IAS 39.

Although it is possible under IAS 39 to exclude the time value of a hedging option and the forward element of a forward contract from the hedging derivative, similar to IFRS 9 (see sections 3.6.4 and 3.6.5 above), the accounting treatment of the excluded components differ. Under IAS 39, it is not possible to apply the costs of hedging accounting to the excluded time value of an option or the forward element of a forward contract (see section 7.5 above). Accordingly, the excluded portions will remain at fair value through profit or loss. So, although the excluded time value or forward element do not affect the hedge effectiveness assessment (see section 13.4 above), they are likely to result in profit or loss volatility under IAS 39. [IAS 39.74]. It is also worth noting that under IAS 39 there is no opportunity to exclude the foreign currency basis from a hedging derivative (see sections 7.4.8 and 7.5.3 above).

Under IFRS 9, in a cash flow hedge of a forecast transaction that subsequently results in the recognition of a non-financial asset or liability, or a forecast transaction for a non-financial asset or liability that becomes a firm commitment for which fair value hedging is applied, the entity shall remove the accumulated amount in the cash flow hedge reserve and include it directly in the initial cost or other carrying amount of the asset or liability (see section 7.2.2 above). Although IAS 39 allows this same treatment, it also permits an accounting policy choice for the amounts accumulated in the cash flow hedge reserve to be reclassified to profit or loss in the same period or periods during which the assumed asset or liability affects profit or loss. [IAS 39.98, IAS 39.99]. Where an accounting policy of adjusting such non-financial assets or liabilities is applied, unlike under IFRS 9 this reclassification adjustment is reported in the statement of OCI. [IFRS 9.6.5.11(d)(i)].

IFRS 9 includes two alternatives to hedge accounting: the fair value option for credit risk exposures (see section 11.1 above) and a fair value option for own use contracts (see section 11.2 above). Neither of these alternatives are available under IAS 39.

Appendix B - Defined terms

Extract from IFRS standards - Definitions

amortised cost of a financial asset or financial liability	The amount at which the financial asset or financial liability is measured at initial recognition minus the principal repayments, plus or minus the cumulative amortisation using the effective interest method of any difference between that initial amount and the maturity amount and, for financial assets, adjusted for any loss allowance . [IFRS 9 Appendix A].
credit risk	The risk that one party to a financial instrument will cause a financial loss for the other party by failing to discharge an obligation. [IFRS 7 Appendix A].
currency risk	The risk that the fair value or future cash flows of a financial instrument will fluctuate because of changes in foreign exchange rates. [IFRS 7 Appendix A].
derecognition	The removal of a previously recognised financial asset or financial liability from an entity's statement of financial position. [IFRS 9 Appendix A].
derivative	A financial instrument or other contract within the scope of this Standard with all three of the following characteristics. (a) its value changes in response to the change in a specified interest rate, financial instrument price, commodity price, foreign exchange rate, index of prices or rates, credit rating or credit index, or other variable, provided in the case of a non-financial variable that the variable is not specific to a party to the contract (sometimes called the 'underlying'). (b) it requires no initial net investment or an initial net investment that is smaller than would be required for other types of contracts that would be expected to have a similar response to changes in market factors. (c) it is settled at a future date. [IFRS 9 Appendix A].
dividends	Distributions of profits to holders of equity instruments in proportion to their holdings of a particular class of capital. [IFRS 9 Appendix A].
effective interest method	The method that is used in the calculation of the amortised cost of a financial asset or a financial liability and in the allocation and recognition of the interest revenue or interest expense in profit or loss over the relevant period. [IFRS 9 Appendix A].
effective interest rate	The rate that exactly discounts estimated future cash payments or receipts through the expected life of the financial asset or financial liability to the gross carrying amount of a financial asset or to the amortised cost of a financial liability . When calculating the effective interest rate, an entity shall estimate the expected cash flows by considering all the contractual terms of the financial instrument (for example, prepayment, extension, call and similar options) but shall not consider the expected credit losses . The calculation includes all fees and points paid or received between parties to the contract that are an integral part of the effective interest rate (see paragraphs B5.4.1-B5.4.3), transaction costs , and all other premiums or discounts. There is a presumption that the cash flows and the expected life of a group of similar financial instruments can be estimated reliably. However, in those rare cases when it is not possible to reliably estimate the cash flows or the expected life of a financial instrument (or group of financial instruments), the entity shall use the contractual cash flows over the full contractual term of the financial instrument (or group of financial instruments). [IFRS 9 Appendix A].

equity instrument	An <i>equity instrument</i> is any contract that evidences a residual interest in the assets of an entity after deducting all of its liabilities. [IAS 32.11].
expected credit losses	The weighted average of credit losses with the respective risks of a default occurring as the weights. [IFRS 9 Appendix A].
fair value	The price that would be received to sell an asset or paid to transfer a liability in an orderly transaction between market participants at the measurement date. [IFRS 13 Appendix A].
financial asset	<p>A <i>financial asset</i> is any asset that is:</p> <ul style="list-style-type: none"> (a) cash; (b) an equity instrument of another entity; (c) a contractual right: <ul style="list-style-type: none"> (i) to receive cash or another financial asset from another entity; or (ii) to exchange financial assets or financial liabilities with another entity under conditions that are potentially favourable to the entity; or (d) a contract that will or may be settled in the entity's own equity instruments and is: <ul style="list-style-type: none"> (i) a non-derivative for which the entity is or may be obliged to receive a variable number of the entity's own equity instruments; or (ii) a derivative that will or may be settled other than by the exchange of a fixed amount of cash or another financial asset for a fixed number of the entity's own equity instruments. <p>For this purpose the entity's own equity instruments do not include puttable financial instruments classified as equity instruments in accordance with paragraphs 16A and 16B, instruments that impose on the entity an obligation to deliver to another party a pro rata share of the net assets of the entity only on liquidation and are classified as equity instruments in accordance with paragraphs 16C and 16D, or instruments that are contracts for the future receipt or delivery of the entity's own equity instruments. [IAS 32.11].</p>
financial guarantee contract	A contract that requires the issuer to make specified payments to reimburse the holder for a loss it incurs because a specified debtor fails to make payment when due in accordance with the original or modified terms of a debt instrument. [IFRS 9 Appendix A].
financial instrument	A <i>financial instrument</i> is any contract that gives rise to a financial asset of one entity and a financial liability or equity instrument of another entity. [IAS 32.11].

financial liability

A *financial liability* is any liability that is:

- (a) a contractual obligation:
 - (i) to deliver cash or another financial asset to another entity; or
 - (ii) to exchange financial assets or financial liabilities with another entity under conditions that are potentially unfavourable to the entity; or
- (b) a contract that will or may be settled in the entity's own equity instruments and is:
 - (i) a non-derivative for which the entity is or may be obliged to deliver a variable number of the entity's own equity instruments; or
 - (ii) a derivative that will or may be settled other than by the exchange of a fixed amount of cash or another financial asset for a fixed number of the entity's own equity instruments. For this purpose, rights, options or warrants to acquire a fixed number of the entity's own equity instruments for a fixed amount of any currency are equity instruments if the entity offers the rights, options or warrants pro rata to all of its existing owners of the same class of its own non-derivative equity instruments. Also, for these purposes the entity's own equity instruments do not include puttable financial instruments that are classified as equity instruments in accordance with paragraphs 16A and 16B, instruments that impose on the entity an obligation to deliver to another party a pro rata share of the net assets of the entity only on liquidation and are classified as equity instruments in accordance with paragraphs 16C and 16D, or instruments that are contracts for the future receipt or delivery of the entity's own equity instruments.

As an exception, an instrument that meets the definition of a financial liability is classified as an equity instrument if it has all the features and meets the conditions in paragraphs 16A and 16B or paragraphs 16C and 16D. [IAS 32.11].

financial liability at fair value through profit or loss

A financial liability that meets one of the following conditions:

- (a) it meets the definition of **held for trading**.
- (b) upon initial recognition it is designated by the entity as at fair value through profit or loss in accordance with paragraph 4.2.2 or 4.3.5.
- (c) it is designated either upon initial recognition or subsequently as at fair value through profit or loss in accordance with paragraph 6.7.1. [IFRS 9 Appendix A].

firm commitment

A binding agreement for the exchange of a specified quantity of resources at a specified price on a specified future date or dates. [IFRS 9 Appendix A].

forecast transaction

An uncommitted but anticipated future transaction. [IFRS 9 Appendix A].

hedge ratio

The relationship between the quantity of the hedging instrument and the quantity of the hedged item in terms of their relative weighting. [IFRS 9 Appendix A].

held for trading	<p>A financial asset or financial liability that:</p> <ul style="list-style-type: none"> (a) is acquired or incurred principally for the purpose of selling or repurchasing it in the near term; (b) on initial recognition is part of a portfolio of identified financial instruments that are managed together and for which there is evidence of a recent actual pattern of short-term profit-taking; or (c) is a derivative (except for a derivative that is a financial guarantee contract or a designated and effective hedging instrument). <i>[IFRS 9 Appendix A].</i>
interest rate risk	<p>The risk that the fair value or future cash flows of a financial instrument will fluctuate because of changes in market interest rates. <i>[IFRS 7 Appendix A].</i></p>
interim financial report	<p>Interim financial report means a financial report containing either a complete set of financial statements (as described in IAS 1 <i>Presentation of Financial Statements</i> (as revised in 2007)) or a set of condensed financial statements (as described in this Standard) for an interim period. <i>[IAS 34.4].</i></p>
market risk	<p>The risk that the fair value or future cash flows of a financial instrument will fluctuate because of changes in market prices. Market risk comprises three types of risk: currency risk, interest rate risk and other price risk. <i>[IFRS 7 Appendix A].</i></p>
regular way purchase or sale	<p>A purchase or sale of a financial asset under a contract whose terms require delivery of the asset within the time frame established generally by regulation or convention in the marketplace concerned. <i>[IFRS 9 Appendix A].</i></p>

Chapter 50

Financial instruments: Presentation and disclosure

Contents

Overview	4302
1 Introduction	4303
1.1 IAS 32	4303
1.2 IFRS 7	4303
2 Scope of IFRS 7	4304
2.1 Entities required to comply with IFRS 7	4304
2.2 Financial instruments within the scope of IFRS 7	4304
2.3 Interim reports	4304
3 Structuring the disclosures	4305
3.1 Level of detail	4305
3.2 Materiality	4305
3.3 Classes of financial instrument	4305
4 Significance of financial instruments for an entity's financial position and performance	4307
4.1 Accounting policies	4307
4.2 Income, expenses, gains and losses	4308
4.2.1 Gains and losses by measurement category	4308
4.2.2 Interest income and expense	4309
4.2.3 Disclosure of terms that could change the timing or amount of contractual cash flows	4309
4.2.4 Fee income and expense	4310
4.3 Hedge accounting	4310
4.3.1 The risk management strategy	4311
4.3.2 The amount, timing and uncertainty of future cash flows	4313
4.3.3 The effects of hedge accounting on financial position and performance	4314
4.3.3.A Costs of hedging	4320
4.3.4 Option to designate a credit exposure as measured at fair value through profit or loss	4322
4.3.5 Uncertainty arising from interest rate benchmark (IBOR) reform	4322
4.4 Statement of financial position	4322
4.4.1 Categories of financial assets and financial liabilities	4322
4.4.2 Financial liabilities designated at fair value through profit or loss	4323
4.4.3 Financial assets designated as measured at fair value through profit or loss	4323
4.4.4 Investments in equity instruments designated at fair value through other comprehensive income	4324

4.4.5	Reclassification	4326
4.4.6	Collateral	4327
4.4.7	Compound financial instruments with multiple embedded derivatives	4327
4.4.8	Defaults and breaches of loans payable	4327
4.4.9	Interests in associates and joint ventures accounted for in accordance with IFRS 9	4328
4.4.10	Contracts Referencing Nature-dependent Electricity	4328
4.5	Fair values	4329
4.5.1	General disclosure requirements	4329
4.5.2	Day 1 profits	4329
4.6	Business combinations	4331
4.6.1	Acquired receivables	4331
4.6.2	Contingent consideration and indemnification assets	4331
5	Nature and extent of risks arising from financial instruments	4332
5.1	Qualitative disclosures	4333
5.2	Quantitative disclosures	4335
5.3	Credit risk	4335
5.3.1	Scope and objectives	4335
5.3.2	Credit risk management practices	4336
5.3.2.A	Application of overlays and post-model adjustments	4337
5.3.3	Quantitative and qualitative information about amounts arising from expected credit losses	4340
5.3.4	Credit risk exposure	4344
5.3.5	Collateral and other credit enhancements obtained	4347
5.3.6	Credit risk: illustrative disclosures	4347
5.4	Liquidity risk	4351
5.4.1	Information provided to key management	4351
5.4.2	Maturity analyses	4352
5.4.2.A	Time bands	4352
5.4.2.B	Cash flows: general requirements	4353
5.4.2.C	Cash flows: borrowings	4354
5.4.2.D	Cash flows: derivatives	4354
5.4.2.E	Cash flows: embedded derivatives	4355
5.4.2.F	Cash flows: financial guarantee contracts and written options	4355
5.4.2.G	Examples of disclosures in practice	4355
5.4.3	Management of associated liquidity risk	4360
5.4.4	Puttable financial instruments classified as equity	4360
5.5	Market risk	4360
5.5.1	'Basic' sensitivity analysis	4361
5.5.2	Value-at-risk and similar analyses	4365
5.5.3	Other market risk disclosures	4367
5.6	Quantitative disclosures: other matters	4367
5.6.1	Concentrations of risk	4367
5.6.2	Operational risk	4368
5.6.3	Capital disclosures	4368
5.7	Interest rate benchmark (or IBOR) reform	4369

6	Transfers of financial assets	4370
6.1	The meaning of 'transfer'	4370
6.1.1	Pass-through type arrangements	4370
6.2	Transferred financial assets that are not derecognised in their entirety	4372
6.3	Transferred financial assets that are derecognised in their entirety	4374
6.3.1	Meaning of continuing involvement	4374
6.3.2	Changes to continuing involvement after time of transfer	4375
6.3.3	Continuing involvement from a consolidated perspective	4376
6.3.4	Disclosure requirements	4376
7	Presentation on the face of the financial statements and related disclosures	4380
7.1	Gains and losses recognised in profit or loss	4380
7.1.1	Presentation on the face of the statement of comprehensive income (or income statement)	4380
7.1.2	Further analysis of gains and losses recognised in profit or loss	4383
7.1.3	Offsetting and hedges	4384
7.1.4	Embedded derivatives	4384
7.1.5	Entities whose share capital is not equity	4385
7.2	Gains and losses recognised in other comprehensive income	4386
7.3	Statement of changes in equity	4386
7.4	Statement of financial position	4387
7.4.1	Offsetting financial assets and financial liabilities	4387
7.4.1.A	Criterion (a): Enforceable legal right of set-off	4388
7.4.1.B	Master netting agreements	4390
7.4.1.C	Criterion (b): Intention to settle net or realise the gross amount simultaneously ('the net settlement criterion')	4390
7.4.1.D	Situations where offset is not normally appropriate	4391
7.4.1.E	Cash pooling arrangements	4392
7.4.1.F	Offsetting collateral amounts	4393
7.4.1.G	Unit of account	4394
7.4.2	Offsetting financial assets and financial liabilities: disclosure	4394
7.4.2.A	Objective	4394
7.4.2.B	Scope	4394
7.4.2.C	Disclosure requirements	4395
7.4.2.D	Offsetting disclosures - illustrative examples	4396
7.4.3	Assets and liabilities	4400
7.4.3.A	Supply chain financing and reverse factoring arrangements - introduction	4401
7.4.3.B	Supply chain financing and reverse factoring arrangements - presentation in the statement of financial position	4402
7.4.3.C	Supply chain financing and reverse factoring arrangements - derecognition of a financial liability	4403
7.4.3.D	Supply chain financing and reverse factoring arrangements - presentation in the statement of cash flows	4403
7.4.3.E	Supply chain financing and reverse factoring arrangements - notes to the financial statements	4403
7.4.3.F	Supply chain financing and reverse factoring arrangements - amendments to IAS 7 and IFRS 7	4404

7.4.4	The distinction between current and non-current assets and liabilities	4404
7.4.4.A	Derivatives	4405
7.4.4.B	Convertible loans	4407
7.4.4.C	Long-term loans with repayment on demand terms	4407
7.4.4.D	Debt with refinancing or roll over agreements	4408
7.4.4.E	Loan covenants	4408
7.4.5	Equity	4408
7.4.6	Entities whose share capital is not equity	4409
7.5	Statement of cash flows	4410

Overview

Disclosure of financial instruments is largely dealt with in IFRS 7 *Financial Instruments: Disclosures* and presentation in IAS 32 *Financial Instruments: Presentation*.

IFRS 7 applies to both financial and non-financial institutions and the disclosures required will depend on the extent of an entity's use of financial instruments and its exposure to risk. IAS 32 addresses when an entity offsets financial assets and financial liabilities amongst other things.

This chapter summarises the presentation and disclosure requirements within IFRS 7 and IAS 32. The disclosures prescribed in IFRS 7 can be split into two broad categories. The first category is quantitative disclosures about the amounts in the statement of financial position and the statement of comprehensive income. The second category is the quantitative and qualitative risk disclosures which require detail on the nature and extent of risks an entity is exposed to because of financial instruments. The purpose of these disclosure requirements is to allow users of the financial statements to assess the significance of financial instruments on an entity's financial position and performance. The risk disclosures are required to be given 'through the eyes of management' and should reflect the way in which management perceives, measures, and manages the entity's risks.

IFRS 7 requires that for each class of financial assets and financial liabilities, the fair value of those classes of assets and liabilities are disclosed to permit comparisons with the associated carrying amount. This is briefly discussed in section 4.5.1, however the more detailed disclosures about fair value are required by IFRS 13 *Fair Value Measurement*, and these are discussed in Chapter 15.

This chapter discusses some of the practical issues associated with the disclosure requirements for transfers of financial assets in section 6 below.

The offsetting requirements of IAS 32 are discussed in section 7.4.1 below. The classification of financial instruments as equity, financial liabilities or financial assets, as prescribed by IAS 32, is covered in Chapter 43.

During 2024, the IASB issued amendments to IFRS 9 *Financial Instruments* regarding the classification and measurement of financial assets and contracts referencing nature-dependent electricity. Consequential amendments were made to IFRS 7 for these changes requiring entities to make the following disclosures:

- Additional information about financial assets and liabilities with contractual terms that reference contingent events (including those that are ESG linked) and equity instruments classified in at fair value through other comprehensive income. These disclosure requirements are addressed in section 4.2.3 and section 4.4.4 below
- Details of contracts referencing nature-dependent electricity that are excluded from the scope of IFRS 9 as a result of the amendments. These disclosure requirements are addressed in section 4.4.10 below.

There are some types of financial instruments that are exempt from IFRS 7, and which are covered by other chapters, including:

- Certain interests in subsidiaries, associates, and joint ventures when measured in accordance with IAS 27 or IAS 28 - see Chapter 14
- Insurance contracts - see Chapter 51
- Employee benefit plans - see Chapter 31
- An entity's own equity instruments - see Chapter 43
- Share-based payment transactions - see Chapter 30

What you need to know

- The scope of IFRS 7 is wider than that of IFRS 9. Therefore, IFRS 7 can apply to instruments that are not subject to the recognition and measurement provisions of IFRS 9, for example lease liabilities.
- The measurement basis (or bases) and other accounting policies used in preparing the financial statements that are relevant to an understanding of the financial statements are required to be disclosed by IFRS 7.
- IFRS 7 requires qualitative and quantitative disclosures for three main risks: credit risk, liquidity risk and market risk. The required disclosures focus on the risks that arise from financial instruments and the risk management initiatives taken by an entity.
- To offset two or more financial instruments in the statement of financial position, IAS 32 requires that an entity must currently have a legally enforceable right of set-off, and an intention to settle on a net basis or realise the asset and settle the liability simultaneously. The right of set-off must not be contingent on a future event and must be legally enforceable in all of the following circumstances:
 - (i) The normal course of business
 - (ii) An event of default
 - And
 - (iii) An event of insolvency or bankruptcy of the entity or any of the counterparties

1 Introduction

IFRS 7 requires entities to provide disclosures in their financial statements that enable users to evaluate the significance of financial instruments for the entity's financial position during the period and at the end of the reporting period. IAS 32 specifies presentation for financial instruments.

The development of these standards is outlined below.

1.1 IAS 32

The original version of IAS 32 *Financial Instruments: Disclosure and Presentation* was published in March 1995 and, as its title suggested, contained requirements about the disclosures entities were to make about financial instruments. These requirements were superseded by IFRS 7 (see section 1.2 below), which also changed the name of the standard.

One of the topics IAS 32 continues to address is when entities offset financial assets and financial liabilities, the associated requirements for which are discussed in section 7.4.1 below. It also addresses the classification of financial instruments as equity, financial liabilities or financial assets, a topic covered in Chapter 43. IAS 32 has been amended several times since publication, including in December 2011 when the IASB addressed certain practical problems it had identified in its offsetting requirements.

1.2 IFRS 7

IFRS 7 emerged from a project principally focused on revising IAS 30 *Disclosures in the Financial Statements of Banks and Similar Financial Institutions* a standard which, at the time, set out additional disclosure requirements for banks and similar entities. It was published in August 2005 and superseded IAS 30.

The standard has been subject to significant amendment since its original publication, in particular to address concerns raised during the financial crisis. These amendments aimed to improve the disclosures entities provide in a number of areas including liquidity risk, transfers of financial assets, offsetting, and fair values (most of the disclosures for which are now included in IFRS 13, see Chapter 15).

In July 2014, the IASB published a substantially final version of IFRS 9, its replacement for IAS 39 *Financial Instruments: Recognition and Measurement*. The new standard changed the framework for classifying and measuring financial assets and financial liabilities, introduced an expected loss approach for determining impairment losses on financial assets, and amended the requirements for applying hedge accounting. It also made several consequential amendments to IFRS 7, introducing extensive new disclosures in respect of impairment (see section 5.3 below) and hedge accounting (see section 4.3 below), as well as making other changes.

The objective of IFRS 7 is to require entities to provide disclosures in their financial statements that enable users to evaluate: [IFRS 7.1]

- The significance of financial instruments for the entity's financial position and performance
- And
- The nature and extent of risks arising from financial instruments to which the entity is exposed during the period and at the reporting date, and how the entity manages those risks

These objectives manifest themselves in two disclosure principles (see section 4 and section 5 below) which are designed to complement those for recognising, measuring and presenting financial assets and financial liabilities in IAS 32 and IFRS 9. [IFRS 7.2].

2 Scope of IFRS 7

2.1 Entities required to comply with IFRS 7

Although IFRS 7 evolved from a project to update IAS 30 (which applied only to banks and similar financial institutions), it applies to all entities preparing their financial statements in accordance with IFRS accounting standards that have financial instruments. [IFRS 7.BC6]. The IASB considered exempting certain entities, including insurers, subsidiaries, and those that are small or medium-sized (SMEs), but decided that IFRS 7 should apply to all entities applying IFRS accounting standards. [IFRS 7.BC9, IFRS 7.BC10, IFRS 7.BC11]. Entities applying IFRS for SMEs are required to provide only reduced disclosures about financial instruments.

2.2 Financial instruments within the scope of IFRS 7

Chapter 41 contains a detailed explanation of the scope of IFRS 7. It is important to recognise that the scope of IFRS 7 is generally wider than that of IFRS 9. Therefore, IFRS 7 can apply to instruments that are not subject to the recognition and measurement provisions of IFRS 9. [IFRS 7.4]. For example, lease liabilities and certain loan commitments are within the scope of IFRS 7 even though they are not, or not wholly, within the scope of IFRS 9. Similarly, financial instruments that are unrecognised due to the application of settlement date accounting are also within the scope of IFRS 7 but not IFRS 9. Conversely, some financial instruments within the scope of IFRS 9, particularly those held in disposal groups or as part of discontinued operations, are not subject to all of the requirements in IFRS 7.

2.3 Interim reports

IAS 34 *Interim Financial Reporting* sets out the minimum content of an interim financial report. When an event or transaction is significant to an understanding of the changes in an entity's financial position or performance since the last annual financial period, IAS 34 requires the report to provide an explanation of, and update to, the information included in the last annual financial statements. [IAS 34.15]. The standard emphasises that relatively insignificant updates need not be provided. [IAS 34.15A]. The following disclosures which relate to financial instruments are required if significant: [IAS 34.15B]

- Losses recognised from the impairment of financial assets
 - Changes in the business or economic circumstances that affect the fair value of the entity's financial assets and financial liabilities, whether recognised at fair value or amortised cost
 - Any loan default or breach of a loan agreement that has not been remedied on, or before, the end of the reporting period
 - Transfers between levels of the fair value hierarchy used in the measurement of the fair value of financial instruments
- And
- Changes in the classification of financial assets as a result of a change in the purpose, or use of, those assets

In considering the extent of disclosures necessary to meet the requirements above, IAS 34 refers to the guidance included in other IFRS accounting standards, [IAS 34.15C], which would include IFRS 7, but does not ordinarily require compliance with all the requirements in those standards.

IAS 34 also specifies additional disclosures to be given (normally on a financial year-to-date basis) about the fair value of financial instruments, including those discussed in section 4.5 below and a number required by IFRS 13. [IAS 34.16A(j)]. This requirement is not subject to the qualifications noted above and so, as discussed in further detail in Chapter 37, these disclosures must always be given unless the information is not material.

The disclosures about offsetting of financial assets and financial liabilities (see section 7.4.2 below) need not be provided in condensed interim financial statements unless required by the more general requirements of IAS 34. [IFRS 7.BC72B, IFRS 7.BC72C].

3 Structuring the disclosures

The main text of IFRS 7 is supplemented by application guidance, which is an integral part of the standard,¹ and by implementation guidance, which accompanies, but is not part of, the standard.² The implementation guidance suggests possible ways of applying some of the requirements of the standard but, it is emphasised, does not create additional requirements. [IFRS 7.IG1].

Although the implementation guidance discusses each disclosure requirement in IFRS 7 separately, disclosures would normally be presented as an integrated package and individual disclosures might satisfy more than one requirement. For example, information about concentrations of risk might also convey information about exposure to credit or other risks. [IFRS 7.IG2]. This chapter follows a similar approach, whereby each topic is considered individually in the context of the requirements of the standard, as well as related application and implementation guidance.

3.1 Level of detail

Entities need to decide, in the light of their circumstances, how much detail to provide to satisfy the requirements of IFRS 7, how much emphasis to place on different aspects of the requirements, and how information is aggregated to display the overall picture without combining information with different characteristics. It is necessary to strike a balance between overburdening financial statements with excessive detail that may not assist users of financial statements and obscuring important information as a result of too much aggregation. For example, important information must not be obscured by including it among a large amount of insignificant detail. Similarly, information must not be aggregated so that it obscures important differences between individual transactions or associated risks. [IFRS 7.B3].

This means that not all of the information suggested, say, in the implementation guidance is necessarily required. [IFRS 7.IG5]. On the other hand, there is a reminder that IAS 1 *Presentation of Financial Statements*³ requires additional disclosures when compliance with the specific requirements in IFRS accounting standards are insufficient to enable users to understand the impact of particular transactions, other events and conditions on the entity's financial position and financial performance (see Chapter 3). [IFRS 7.IG6].

3.2 Materiality

The implementation guidance to the original version of IFRS 7 drew attention to the definition of materiality in IAS 1 (see Chapter 3), noting that a specific disclosure requirement need not be satisfied if the information is not material. [IFRS 7(2010).IG3]. The inclusion of such guidance was intended to provide a degree of reassurance that entities with few financial instruments and few risks (for example a manufacturer whose only financial instruments are accounts receivable and accounts payable) will give few disclosures, something that was borne out in other references within the standard and accompanying material. [IFRS 7.BC10]. Nevertheless, in May 2010, the IASB removed these references to materiality from IFRS 7 because they thought that they could imply that other disclosures in IFRS 7 are required even if those disclosures are not material, which was not the intention. [IFRS 7.BC47A].

3.3 Classes of financial instrument

Certain disclosures required by IFRS 7 must be provided by class of financial instrument (see section 4.5.1, section 4.5.2, section 5.3 and section 6 below). For these, entities should group financial instruments into classes that are appropriate to the nature of the information disclosed and take into account the characteristics of those instruments. [IFRS 7.6]. It is clear from this requirement that the classes used need not be the same for each disclosure provided, e.g., one set of classes may be used to present information about credit risk (see section 5.3 below) and another for information about day 1 profits (see section 4.5.2 below).

¹ IFRS 7, Appendix B, Application guidance, sentence after main heading.

² IFRS 7, Guidance on implementing, sentence after main heading.

³ IFRS 18 *Presentation and Disclosure in Financial Statements*, which supersedes IAS 1 for reporting periods beginning on or after 1 January 2027 (with earlier application permitted) was issued by the IASB in April 2024. On adoption of IFRS 18 these aspects of IAS 1 are relocated to a renamed IAS 8 *Basis of Preparation of Financial Statements* and the cross-reference in IFRS 7.IG6 is amended accordingly.

It is emphasised that these classes are determined by the entity and are, thus, distinct from the categories of financial instruments specified in IFRS 9, which determines how financial instruments are measured and where changes in fair value are recognised. [IFRS 7.B1]. However, in determining classes of financial instruments an entity must, as a minimum, distinguish instruments measured at amortised cost from those measured at fair value, and treat as a separate class or classes those financial instruments outside the scope of IFRS 7. [IFRS 7.B2].

For disclosures given by class of instrument, sufficient information must be provided to permit the information to be reconciled to the line items presented in the statement of financial position. [IFRS 7.6].

4 Significance of financial instruments for an entity's financial position and performance

The IASB decided that the disclosure requirements in this area must result from the following disclosure principle: [IFRS 7.7]

Extract from IFRS 7

- 7** An entity shall disclose information that enables users of its financial statements to evaluate the significance of financial instruments for its financial position and performance.

Furthermore, they concluded that this principle could not be satisfied unless other specified disclosures (which are dealt with in sections 4.1 to 4.5 below) are also provided. [IFRS 7.7, IFRS 7.BC13].

4.1 Accounting policies

The main body of IFRS 7 contains a reminder of IAS 1's⁴ requirement for an entity to disclose its material accounting policy information, which is discussed in Chapter 3, and goes on to explain that the measurement basis (or bases) for financial instruments used in preparing the financial statements would be expected to be material accounting policy information. [IFRS 7.21].

For financial assets and financial liabilities designated as measured at fair value through profit or loss (see Chapter 44), such disclosure may include: [IFRS 7.B5(a), IFRS 7.B5(aa)]

- The nature of the financial assets or financial liabilities designated as measured at fair value through profit or loss
- The criteria for so designating financial liabilities on initial recognition
- And
- How the conditions or criteria in IFRS 9 for such designation have been satisfied

Other accounting policy information that might be appropriate includes: [IFRS 7.B5(c), IFRS 7.B5(e)]

- Whether regular way purchases and sales of financial assets are accounted for at trade date or at settlement date (see Chapter 45)
- And
- How net gains or net losses on each category of financial instrument are determined (see section 4.2.1 below), for example whether the net gains or net losses on items measured at fair value through profit or loss include interest or dividend income

Although related, different considerations will apply to the requirement to present separately on the face of the statement of comprehensive income (or income statement) interest revenue calculated using the effective interest method - see section 7.1.1 below.

How we see it

In our view, when determining the net gains or losses on each category of financial instrument, interest income and interest expense (including, for example, that arising on short positions) must be treated consistently, i.e., both included or both excluded from the net gains and losses disclosed.

The application guidance also contains a reminder that IAS 1 (IAS 8)⁵ requires entities to disclose the judgements, apart from those involving estimations, that management has made in the process of applying the entity's accounting policies and that have the most significant effect on the amounts recognised in the financial statements (see Chapter 3). [IFRS 7.B5] [IAS 1.122] [IAS 8(2027).27G]. These might include those an entity has used in applying hedge accounting requirements of IFRS 9, for example those made in determining whether an economic relationship exists between the hedged item and the hedging instrument, how the hedge ratio was set, and how risk components were identified.

⁴ IFRS 18, which supersedes IAS 1 for reporting periods beginning on or after 1 January 2027 (with earlier application permitted) was issued by the IASB in April 2024. On adoption of IFRS 18 these aspects of IAS 1 are relocated to paragraph 27A of the renamed IAS 8 *Basis of Preparation of Financial Statements* and the cross-reference in IFRS 7.21 is amended accordingly.

⁵ On adoption of IFRS 18, these aspects of IAS 1 are relocated to paragraph 27G of the renamed IAS 8 *Basis of Preparation of Financial Statements* for reporting periods beginning on or after 1 January 2027 (with earlier application permitted) and the cross-reference in IFRS 7.B5 is amended accordingly.

4.2 Income, expenses, gains and losses

Under IFRS 7, entities are required to disclose various items of income, expense, gains and losses. The disclosures below may be provided either on the face of the financial statements, subject to the requirements of IAS 1 or, when applied, IFRS 18 *Presentation and Disclosure in Financial Statements*, or in the notes. [IFRS 7.20]. However, in this context, it should be noted that IAS 1 does require certain line items to be disclosed separately in the profit or loss section of the statement of profit or loss (see section 7.1.1 below). IFRS 18 is even more specific about the presentation of items within profit or loss (see Chapter 4 for further details) which could lead to more of these disclosures being given in the notes.

4.2.1 Gains and losses by measurement category

The IASB concluded that information about the gains and losses arising on the various measurement categories of instrument is necessary to understand the financial performance of an entity's financial instruments given the different measurement bases used. Consequently, disclosure must be given of net gains or net losses arising on the following categories of instruments: [IFRS 7.20(a)]

- Financial assets or financial liabilities measured at fair value through profit or loss, showing separately those on financial assets or liabilities:
 - Designated as such upon initial recognition (or subsequently when the credit risk of a financial asset is managed using a credit derivative)
 - And
 - Mandatorily measured at fair value in accordance with IFRS 9, e.g., liabilities held for trading
 For financial liabilities designated at fair value through profit or loss, the amount of gain or loss recognised in other comprehensive income, i.e., relating to changes in fair value attributable to changes in credit risk (see Chapter 46), must be shown separately.

How we see it

For financial instruments measured at fair value through profit or loss, it would be appropriate for interest expense on short positions to be presented in a manner consistent with the treatment of interest expense on long positions, i.e., either included in interest expense or in gains and losses on financial instruments at fair value through profit or loss as appropriate. The presentation is to be consistent from period to period and appropriate disclosure should be made in the entity's accounting policy.

- Financial assets measured at amortised cost:
All gains and losses must also be presented separately and the reasons for derecognition must also be given. [IFRS 7.20A]. Also, the total gains and losses must be shown separately on the face of the income statement or statement of comprehensive income (see section 7.1.1 below). [IAS 1.82(aa), IFRS 18.75(b)(iii)].
- Financial liabilities measured at amortised cost

How we see it

In our view, if financial liabilities that are not at fair value through profit and loss (i.e., measured at amortised cost) are used to finance a portfolio of trading financial assets (for example, trading debt securities), it would be inappropriate to include the interest expense (funding costs) on such liabilities in net gains or net losses on financial assets or financial liabilities at fair value through profit or loss.

- Investments in equity instruments designated at fair value through other comprehensive income
- And
- Financial assets that are debt instruments measured at fair value through other comprehensive income, showing separately:
 - The amount of gain or loss recognised in other comprehensive income during the period
 - And
 - The amount reclassified upon derecognition from accumulated other comprehensive income to profit or loss for the period

These disclosures are designed to complement the statement of financial position disclosure requirement described in section 4.4.1 below. [IFRS 7.BC33].

The following is required to be disclosed in relation to interest and dividend income: [IFRS 7.BC34]

Extract from IFRS 7

BC34 Some entities include interest and dividend income in gains and losses on financial assets and financial liabilities measured at fair value through profit or loss and others do not. To assist users in comparing income arising from financial instruments across different entities, the Board decided that an entity should disclose how the income statement amounts are determined. For example, an entity should disclose whether net gains and losses on financial assets or financial liabilities measured at fair value through profit or loss include interest and dividend income (see Appendix B, paragraph B5(e)).

4.2.2 Interest income and expense

For financial assets or financial liabilities that are not measured at fair value through profit or loss, total interest income and total interest expense (calculated using the effective interest method) must be disclosed. Interest revenue for financial assets measured at amortised cost must be shown separately from interest revenue on debt instruments measured at fair value through other comprehensive income. [IFRS 7.20(b)]. This disclosure requirement is similar, but different, to the requirement to present separately on the face of the statement of comprehensive income (or income statement) interest revenue calculated using the effective interest method - see section 7.1.1 below.

In relation to hedge accounting, IFRS 9 does not explicitly state where in the profit or loss any gains and losses from hedge accounting should be presented. However, it can be inferred that gains and losses from hedging instruments in hedging relationships would normally be presented in the same line item that is affected by the hedged item (at least to the extent the hedge is effective), rather than being shown separately, (see Chapter 49). Therefore, interest income calculated using the effective interest method can include:

- Reclassification adjustments on any hedging instruments (such as derivatives) designated in cash flow hedges of the variability in interest cash flows, in the same periods during which the hedged items expected future cash flows affect profit or loss, i.e., when the interest income is recognised in the income statement [IFRS 9.6.5.11(d)(ii)]

Conversely, lease liabilities and finance lease receivables are within the scope of IFRS 9 (see Chapter 41) but are not accounted for using the effective interest method. There is no equivalent acknowledgement in IFRS 16 *Leases* or IFRS 9 that the disclosure of interest income and interest expense should be made on the basis of the finance cost and finance revenue recognised under the relevant standard for leases. However, this seems little more than an oversight and we consider it appropriate to include in the disclosure the amounts actually recognised under IFRS 16, rather than amounts calculated in accordance with the effective interest method.

As noted above, IFRS 7.20(b) requires disclosure of interest revenue using the effective interest method, however currently there is no specific requirement to disclose information on contractual terms that could affect the timing or amount of cash flows in the future. In 2024, the IASB issued amendments to IFRS 9 and IFRS 7 to help users of financial statements understand the effect of contractual terms that could change the timing or amount of contractual cash flows based on the occurrence (or non-occurrence) of a contingent event that is specific to the debtor. These proposals are discussed further in section 4.2.3 below.

4.2.3 Disclosure of terms that could change the timing or amount of contractual cash flows

In 2024, the IASB issued *Amendments to the Classification and Measurement of Financial Instruments - Amendments to IFRS 9 and IFRS 7* to provide additional clarifications in relation to certain paragraphs related to the classification and measurement requirements of IFRS 9 and amend the related disclosures in IFRS 7.⁶ In particular, additional disclosure requirements have been introduced to help users better understand the effect of contractual terms that could change the timing or amount of contractual cash flows based on the occurrence or non-occurrence of a contingent event that does not relate directly to changes in basic lending risks and costs. Examples of financial instruments that contain such terms are loans and bonds whose interest rates are linked to ESG targets or other contingent features not linked to the time value of money or credit risk of the borrower. This is in contrast to changes in cash flows due to contingent events related to changes in basic lending risks which may include, for example, penalty interest or early repayment triggers due to breaches of debt coverage ratios, missed payments or other proxies of credit risk, if the change in cash flows is commensurate to the change in credit risk of the borrower.

⁶ Amendments to the Classification and Measurement of Financial Instruments - Amendments to IFRS 9 and IFRS 7, IASB, May 2024.

To enable users to assess the entity's future cash flows qualitative and quantitative information about these terms will be required. Entities are required to disclose, by class of financial asset or liability:

- A qualitative description of the nature of the contingent event
- Quantitative information about the possible changes to contractual cash flows that could result from those contractual terms (for example, the range of possible changes)

And

- The gross carrying amount of financial assets and the amortised cost of financial liabilities subject to those contractual terms. [IFRS 7.20C].

The above disclosures are required separately for each class of financial assets measured at amortised cost or fair value through other comprehensive income and for each class of financial liabilities measured at amortised cost. [IFRS 7.20B]. The requirements for determining appropriate classes of instruments are covered in section 3.3 above. This information is not required to be disclosed for financial instruments at fair value through profit and loss as the changes in fair value are considered to provide sufficient information to users to assess the future cash flows of those instruments.

The disclosures above also apply to contingent features of financial assets that do not result in contractual cash flows that are significantly different from those of financial instruments with identical contractual terms but without such features (and are therefore eligible to be measured at amortised cost or fair value through other comprehensive income in accordance with paragraph IFRS 9.B4.1.10A - see Chapter 44). This is because such features may be qualitatively material or material in aggregate across a portfolio of financial assets. [IFRS 7.BC35ZZC].

An entity considers how much detail to disclose, the appropriate level of aggregation or disaggregation, and whether users need additional explanations to evaluate any quantitative information disclosed. [IFRS 7.20B]. For example, an entity discloses this information for a class of financial liabilities measured at amortised cost whose contractual cash flows change if the entity achieves a reduction in its carbon emissions. [IFRS 7.20D].

The amendments are effective for periods beginning on or after 1 January 2026, however entities with annual reporting periods beginning before 1 January 2026 can either early adopt all the amendments at the same time or early adopt only the amendments relating to the classification of financial assets and their related disclosures (as discussed in this section) and apply the other amendments from the effective date.

4.2.4 Fee income and expense

Entities must disclose fee income and expense (excluding amounts included in the effective interest rate calculation) arising from: [IFRS 7.20(c)]

- Financial assets or financial liabilities that are not measured at fair value through profit or loss
- And
- Trust and other fiduciary activities that result in the holding or investing of assets on behalf of individuals, trusts, retirement benefit plans, and other institutions

These disclosures indicate the level of such activities and assist users in estimating the possible future income of the entity. [IFRS 7.BC35].

4.3 Hedge accounting

When developing IFRS 9 many constituents, users in particular, asked for improved disclosures that link more clearly an entity's risk management activities and how it applies hedge accounting. [IFRS 7.BC35C]. Consequently, IFRS 9 has significantly expanded the IFRS 7 disclosure requirements in respect of hedge accounting when compared to the previous IFRS 7 requirements, prior to IFRS 9 being adopted. The requirements are also supplemented by some detailed implementation guidance. The hedge accounting requirements of IFRS 9 are dealt with in Chapter 49.

Under IFRS 9, an entity may choose to continue applying certain, or all, of the hedge accounting requirements of IAS 39, rather than those in IFRS 9 (see Chapter 49). In these circumstances, the disclosure requirements in IFRS 7 that were introduced by IFRS 9 must be followed, rather than those that previously applied under IAS 39. [IFRS 9.BC6.104].

The requirements set out in section 4.3.1 to section 4.3.4 below apply for those risk exposures that an entity hedges and for which it elects to apply hedge accounting. The objective of these disclosures is to provide information about: *[IFRS 7.21A]*

- The entity's risk management strategy and how it is applied to manage risk
Linking the application of hedge accounting to the entity's risk management strategy requires an understanding of the entity's risk management strategy and to facilitate this the IASB has introduced more guidance about the information to be included in a description of the risk management strategy of the entity (see section 4.3.1 below). *[IFRS 7.BC35P]*.
- How the entity's hedging activities may affect the amount, timing, and uncertainty of its future cash flows (see section 4.3.2 below)
And
- The effect that hedge accounting has had on the entity's statement of financial position, statement of comprehensive income and statement of changes in equity (see section 4.3.3 below)

In order to meet these objectives, an entity will need to determine how much detail to disclose, how much emphasis to place on different aspects of the disclosure requirements, the appropriate level of aggregation or disaggregation, and whether additional explanations are needed to evaluate the quantitative information disclosed. The level of aggregation or disaggregation should be consistent with that used for meeting the disclosure requirements of related information elsewhere in IFRS 7 and in IFRS 13 (see Chapter 15). *[IFRS 7.21D]*.

Some of the disclosure requirements in section 4.3.1 to section 4.3.3 below are required to be given by 'risk category'. This is not a defined term but appears to refer to the type of risk being hedged, rather than, say, the type of hedge relationship such as cash flow hedges and fair value hedges. Each risk category should be determined on the basis of the risk exposures an entity decides to hedge and for which hedge accounting is applied. These categories should be determined consistently for all hedge accounting disclosures. *[IFRS 7.21C]*. This should enable users to follow the various disclosures by type of risk, resulting in a much better understanding of the hedging activities and their impact on the financial statements.

These disclosures must be presented in a single note or separate section of the financial statements. To avoid duplication, IFRS 7 allows this information to be incorporated by cross-reference from the financial statements to some other statement that is available to users of the financial statements on the same terms and at the same time, such as a management commentary or risk report. Without the information incorporated by cross-reference, the financial statements are incomplete. *[IFRS 7.21B]*.

4.3.1 The risk management strategy

An entity must explain its risk management strategy for each risk category of risk exposures that it decides to hedge and for which hedge accounting is applied. This explanation should enable users of financial statements to evaluate, for example: *[IFRS 7.22A]*

- How each risk arises
- How each risk is managed
This includes whether the entity hedges an item in its entirety for all risks or hedges a risk component (or components) of an item and why
And
- The extent of risk exposures that are managed

To meet these requirements, the information must include, but is not limited to, a description of: *[IFRS 7.22B]*

- The hedging instruments that are used (and how they are used) to hedge risk exposures
- How the economic relationship between the hedged item and the hedging instrument is determined for the purpose of assessing hedge effectiveness
- How the hedge ratio is established
And
- The sources of hedge ineffectiveness

When a specific risk component is designated as a hedged item, the following disclosure is required: [IFRS 7.22C]

Extract from IFRS 7

- 22C When an entity designates a specific risk component as a hedged item (see paragraph 6.3.7 of IFRS 9) it shall provide, in addition to the disclosures required by paragraphs 22A and 22B, qualitative or quantitative information about:
- (a) how the entity determined the risk component that is designated as the hedged item (including a description of the nature of the relationship between the risk component and the item as a whole); and
 - (b) how the risk component relates to the item in its entirety (for example, the designated risk component historically covered on average 80 per cent of the changes in fair value of the item as a whole).

This information could include a description of whether the risk component is contractually specified, and if not, how the entity determined that the non-contractually specified risk component is separately identifiable and reliably measurable.

The following Illustration shows how an entity might present some of this information.

Illustration 4-1: Illustrative disclosure of risk management strategy for commodity price risk

Coffee price risk

Fluctuations in the coffee price are the main source of market risk for the Alpha Beta Coffee Group (the Group). The Group purchases Arabica coffee from various suppliers in South America. For this purpose, the Group enters into long-term contracts (for between one and three years) with its suppliers, in which the future coffee price is indexed to the USD Arabica benchmark coffee price, adjusted for transport costs that are indexed to diesel prices plus a quality coefficient that is reset annually for a crop period. In order to secure the volume of coffee needed, supply contracts are always entered into (or renewed) at least one year prior to harvest.

The Group forecasts the monthly volume of expected coffee purchases for a period of 18 months and manages the coffee price risk exposure on a 12-month rolling basis. For this purpose, the Group enters into futures contracts on the Arabica benchmark price and designates the futures contracts in cash flow hedges of the USD Arabica benchmark price risk component of its future coffee purchases. Some of those purchases are committed minimum volumes under the contracts and some purchases are highly probable forecast transactions (i.e., quantities in excess of the minimum purchases volumes and sometimes for periods for which no contract has yet been entered into). The underlying risk of the coffee futures contracts is identical to the hedged risk component (i.e., the USD Arabica benchmark price). Therefore, the Group has established a hedge ratio of 1:1 for all its hedging relationships. The USD Arabica benchmark price risk component is contractually specified in its purchase contracts, therefore, the Group considers the risk component to be separately identifiable and reliably measurable based on the price of coffee futures.

The Group does not hedge its exposure to the variability in the purchase price of coffee that results from the annual reset of the quality coefficient, because hedging that risk would require highly bespoke financial instruments that in the Group's view are not economical.

The Group's exposure to the variability in the purchase price of coffee that results from the diesel price indexation of the transport costs is integrated into its general risk management of logistics costs that aggregates exposures resulting from various logistics processes of the Group.

The Group determined the USD Arabica benchmark coffee price risk component that it designates as the hedged item on the basis of the pricing formula in the Group's coffee supply contracts (see the above description). That benchmark component is the largest pricing element. The quality coefficient depends on the particular crop in the region from which the Group sources its coffee, depending mainly on weather conditions that affect size and quality of the crop. Sometimes pest and plant diseases can have similar effects. Over the last 10 crop periods, the quality coefficient ranged between US cents 2-27 per pound (lb). For the effect of the diesel price indexation, refer to the section 'Logistics costs management' in the Risk Management Report that is included in this Annual Report.

More information about how the Group manages its risk, including the extent to which the Group hedges, the hedging instruments used and sources of ineffectiveness, is provided in the Risk Management Report (see section 'Commodity Price Risk Management').

Disclosures about an entity's risk management strategy are an important cornerstone of the hedge accounting model, as they provide the link between an entity's risk management activities and how they affect the financial statements.

4.3.2 The amount, timing and uncertainty of future cash flows

For most hedge relationships, quantitative information must be disclosed by risk category that allows the evaluation of the terms and conditions of the hedging instruments and how they affect the amount, timing and uncertainty of future cash flows. [IFRS 7.23A]. This must include a breakdown disclosing: [IFRS 7.23B]

- The profile of the timing of the hedging instrument's nominal amount
- And
- If applicable, its average price or rate (e.g., strike or forward prices)

This requirement applies to cash flow hedges, fair value hedges, and hedges of a net investment, and meeting this requirement with concise information could prove challenging where an entity's use of hedge accounting is extensive. The following Illustration shows how an entity might present some of this information.

Illustration 4-2: Illustrative disclosure of timing, nominal amount and average price of coffee futures contracts

As of 31 December 20X0, Alpha Beta Coffee Group is holding the following coffee futures contracts to hedge the exposure on its coffee purchases over the next twelve months:

	Jan	Feb	Mar	Apr	May	...	Dec	Total
Notional amount of coffee futures contracts (in lb thousands) by month of their maturity	1,275	1,425	1,350	1,312	1,350	...	1,200	16,275
Average hedged rate (in US cents per lb)	122	125	128	133	135	...	139	133

Where a dynamic hedging process is used, an entity is exempt from the disclosure requirements in IFRS 7.23A and IFRS 7.23B and different information should be given. [IFRS 7.23A, IFRS 7.23B]. A dynamic process may be used in which both the exposure and the hedging instruments used to manage that exposure remain the same for only short periods of time because both the hedging instrument and the hedged item frequently change and the hedging relationship is frequently reset (or discontinued and restarted). This might occur, for example, when hedging the interest rate risk of an open portfolio of debt instruments. In these situations, the following must be disclosed: [IFRS 7.23C(b)]

- Information about what the ultimate risk management strategy is in relation to those hedging relationships
- A description of how the risk management strategy is reflected by using hedge accounting and designating those particular hedging relationships
- And
- An indication of how frequently the hedging relationships are discontinued and restarted as part of the process in relation to those hedging relationships

When the volume of hedging relationships in a dynamic process is unrepresentative of normal volumes during the period (i.e., the volume at the reporting date does not reflect the volumes during the period), that fact must be disclosed along with the reason volumes are believed to be unrepresentative. [IFRS 7.24D].

For all hedges, a description of the sources of hedge ineffectiveness that are expected to affect the hedging relationship during its term must be disclosed by risk category. [IFRS 7.23D]. If other sources of hedge ineffectiveness emerge in a hedging relationship, those sources must be disclosed by risk category along with an explanation of the resulting hedge ineffectiveness. [IFRS 7.23E].

For cash flow hedges, a description of any forecast transaction for which hedge accounting had been used in the previous period, but which is no longer expected to occur, must be disclosed. [IFRS 7.23F].

Originally the IASB had proposed that entities should disclose the total volume of risk the entity managed, irrespective of whether the entity actually hedges the full exposure. However, they were persuaded by many constituents saying this could result in disclosure of commercially sensitive information and did not carry this requirement forward to the final standard. [IFRS 7.BC35U, IFRS 7.BC35W, IFRS 7.BC35X].

4.3.3 The effects of hedge accounting on financial position and performance

The following amounts related to designated hedging instruments must be disclosed:

- The carrying amount of the hedging instruments, presenting financial assets separately from financial liabilities.
- The line item in the statement of financial position that includes the hedging instrument.
- The change in fair value of the hedging instrument used as the basis for recognising hedge ineffectiveness for the period.

And

- The nominal amounts (including quantities such as tonnes or cubic metres) of the hedging instruments.
- This information should be given in a tabular format, separately by risk category and for fair value hedges, cash flow hedges and hedges of a net investment in a foreign operation, [IFRS 7.24A], and the implementation guidance suggests it might be given in the following format. [IFRS 7.IG13C].

Illustration 4-3: Amounts related to hedged instruments

	Nominal amount of the hedging instrument	Carrying amount of the hedging instrument		Line item in the statement of financial position where the hedging instrument is located	Changes in fair value used for calculating hedge ineffectiveness for 20X1
		Assets	Liabilities		
Cash flow hedges					
Commodity price risk					
- Forward sales contracts	xx	xx	xx	Line item XX	xx
Fair value hedges					
Interest rate risk					
- Interest rate swaps	xx	xx	xx	Line item XX	xx
Foreign exchange risk					
- Foreign currency loan	xx	xx	xx	Line item XX	xx

The following amounts related to hedged items must be disclosed:

- For fair value hedges: [IFRS 7.24B(a)]
 - The carrying amount of the hedged item recognised in the statement of financial position, presenting assets separately from liabilities
 - The accumulated amount of adjustments to the hedged item included in its carrying amount, again presenting assets separately from liabilities
 - The line item in the statement of financial position that includes the hedged item
 - The change in value of the hedged item used as the basis for recognising hedge ineffectiveness for the period
- And
- The accumulated amount of adjustments to hedged financial instruments measured at amortised cost that have ceased to be adjusted for hedging gains and losses and which remain in the statement of financial position

- For cash flow hedges and hedges of a net investment in a foreign operation: [IFRS 7.24B(b)]
 - The change in value of the hedged item used as the basis for recognising hedge ineffectiveness for the period
 - The balances in the cash flow hedge reserve and the foreign currency translation reserve for continuing hedges
 And
 - The balances remaining in the cash flow hedge reserve and the foreign currency translation reserve from any hedging relationships for which hedge accounting is no longer applied

This information should be given in a tabular format, separately by risk category, [IFRS 7.24B], and the implementation guidance suggests it might be given in the following format. [IFRS 7.IG13D].

Illustration 4-4: Amounts related to hedged items

		Carrying amount of the hedged item		Accumulated amount of fair value hedge adjustments on the hedged item included in the carrying amount of the hedged item		Line item in the statement of financial position in which the hedged item is included	Change in value used for calculating hedge ineffectiveness for 20X1	Cash flow hedge reserve
		Assets	Liabilities	Assets	Liabilities			
Cash flow hedges								
Commodity price risk								
-	Forecast sales	n/a	n/a	n/a	n/a	n/a	xx	xx
-	Discontinued hedges (forecast sales)	n/a	n/a	n/a	n/a	n/a	n/a	xx
Fair value hedges								
Interest rate risk								
-	Loan payable	-	xx	-	xx	Line item XX	xx	n/a
-	Discontinued hedges (Loan payable)	-	xx	-	xx	Line item XX	n/a	n/a
Foreign exchange risk								
-	Firm commitment	xx	xx	xx	xx	Line item XX	xx	n/a

The following amounts affecting the statement of comprehensive income must be disclosed:

- For fair value hedges: [IFRS 7.24C(a)]
 - Hedge ineffectiveness, i.e., the difference between the hedging gains or losses of the hedging instrument and the hedged item, recognised in profit or loss (or other comprehensive income for hedges of an equity instrument for which changes in fair value are presented in other comprehensive income)
 And
 - The line item in the statement of comprehensive income that includes the recognised hedge ineffectiveness

- For cash flow hedges and hedges of a net investment in a foreign operation: [IFRS 7.24C(b)]
 - Hedging gains or losses that were recognised in other comprehensive income in the reporting period
 - Hedge ineffectiveness recognised in profit or loss
 - The line item in the statement of comprehensive income that includes the recognised hedge ineffectiveness
 - The amount reclassified from the cash flow hedge reserve or the foreign currency translation reserve into profit or loss as a reclassification adjustment, differentiating in the case of cash flow hedges between:
 - Amounts for which hedge accounting had previously been used, but for which the hedged future cash flows are no longer expected to occur
 - And
 - Amounts that have been transferred because the hedged item has affected profit or loss
 - The line item in the statement of comprehensive income that includes the reclassification adjustment
 - And
 - For hedges of net positions, the hedging gains or losses recognised in a separate line item in the statement of comprehensive income

This information should be given in a tabular format, separately by risk category, [IFRS 7.24C], and the implementation guidance suggests it might be given in the following format. [IFRS 7.IG13E].

Illustration 4-5: Amounts affecting the statement of comprehensive income

Cash flow hedges ^(a)	Separate line item recognised in profit or loss as a result of a hedge of a net position ^(b)	Change in the value of the hedging instrument recognised in other comprehensive income	Hedge ineffectiveness recognised in profit or loss	Line item in profit or loss (that includes hedge ineffectiveness)	Amount re-classified from the cash flow hedge reserve to profit or loss	Line item affected in profit or loss because of the re-classification
Commodity price risk Commodity X	n/a	xx	xx	Line item XX	xx	Line item XX
▪ Discontinued hedge	n/a	n/a	n/a	n/a	xx	Line item XX

(a) The information disclosed in the statement of changes in equity (cash flow hedge reserve) should have the same level of detail as these disclosures.

(b) This disclosure only applies to cash flow hedges of foreign currency risk.

Fair value Hedges	Ineffectiveness recognised in profit or loss	Line item(s) in profit or loss (that include(s) hedge ineffectiveness)
Interest rate risk	xx	Line item XX
Foreign exchange risk	xx	Line item XX

The following Illustration shows another way an entity might present this information.

Illustration 4-6: Illustrative disclosure of the effects of hedge accounting on the financial position and performance

The impact of hedging instruments designated in hedging relationships as of 31 December 20X1 on the statement of financial position of Alpha Beta Coffee Group (the Group) is as follows:

Cash flow hedges	Notional amount	Carrying amount	Line item in the statement of financial position	Change in fair value used for measuring ineffectiveness for the period
Coffee price risk				
Arabica coffee futures	16,275lbs (thousands)	(4.5)	Short-term derivative financial liabilities	(1.0)
Interest rate risk				
Pay fixed/receive variable interest rate swap	EUR 50m	4.0	Long-term derivative financial assets	1.0

Fair value hedges	Notional amount	Carrying amount	Line item in the statement of financial position	Change in fair value used for measuring ineffectiveness for the period
Interest rate risk				
Receive fixed/pay variable interest rate swap	EUR 200m	(10.0)	Long-term derivative financial liabilities	(2.0)

The impact of hedged items designated in hedging relationships as of 31 December 20X1 on the statement of financial position of the Group is as follows:

Cash flow hedges	Change in value used for measuring ineffectiveness	Cash flow hedge reserve
Coffee price risk		
Coffee purchases	1.0	4.5
Interest rate risk		
Forecast interest payments	(0.9)	(3.9)

Fair value hedges	Carrying amount	Thereof accumulated fair value adjustments	Line item in the statement of financial position	Change in fair value used for measuring ineffectiveness for the period
Interest rate risk				
Fixed rate borrowings	211.0	11.0	Long-term borrowings	2.1

The above hedging relationships affected profit or loss and other comprehensive income as follows:

Cash flow hedges	Hedging gain or loss recognised in OCI	Ineffectiveness recognised in profit or loss	Line item in the statement of profit or loss for ineffectiveness	Amount reclassified from OCI to profit or loss	Line item in the statement of profit or loss for reclassification
Coffee price risk					
Hedges of forecast coffee purchases	(1.0)				
Interest rate risk					
Forecast interest payments	0.9	0.1	Other financial income	0.5	Interest expense

Fair value hedges	Ineffectiveness recognised in profit or loss	Line item in the statement of profit or loss for ineffectiveness
Interest rate risk		
Hedge of fixed rate borrowings	(0.1)	Other financial expenses

IAS 1 or, when applied, IFRS 18, requires the presentation of a reconciliation of each component of equity and an analysis of other comprehensive income (see section 7.2 and section 7.3 below). The level of information given in the reconciliation and analysis must: [IFRS 7.24E]⁷

- Differentiate between hedging gains or losses recognised in other comprehensive income and amounts reclassified to profit or loss, separately for:
 - Cash flow hedges for which the hedged future cash flows are no longer expected to occur
 - Those hedges for which the hedged item has affected profit or loss
 And
 - Amounts related to hedged forecast transactions that subsequently result in the recognition of a non-financial asset or liability, or a hedged forecast transaction for a non-financial asset or liability becomes a firm commitment for which fair value hedge accounting is applied, that are included directly in the initial cost or other carrying amount of the asset or the liability
 As noted in section 7.2 and section 7.3 below, this adjustment should not be included within other comprehensive income. [IFRS 9.BC6.380]. Instead, it should be presented within the statement of changes of equity, albeit separately from other comprehensive income.
 - Differentiate between amounts associated with the time value of options that hedge transaction related hedged items and those that hedge time-period related hedged items where the time value of the option is recognised initially in other comprehensive income
- And
- Differentiate between amounts associated with forward elements of forward contracts and the foreign currency basis spreads of financial instruments that hedge transaction related hedged items and those that hedge time-period related hedged items where those amounts are recognised initially in other comprehensive income (see section 4.3.3.A below)

The information in the bullets above must be provided separately by risk category, although this disaggregation may be disclosed in the notes to the financial statements. [IFRS 7.24F].

The following extract from the financial statements of Vodafone Group Plc shows the type of disclosure about hedge accounting and hedge relationships that can be seen in practice. In addition to the information shown below, the table in the financial statements also includes, where relevant, the average maturity year, average foreign currency rate and average euro interest rate for each of the relevant line items.

⁷ IFRS 18, which supersedes IAS 1 for reporting periods beginning on or after 1 January 2027 (with earlier application permitted), was issued by the IASB in April 2024. On adoption of IFRS 18 these aspects of IAS 1 and the cross-reference in IFRS 7.24E is amended accordingly.

Practical example 4-1: Vodafone Group Plc (2024)

United Kingdom

Annual Report 2024 [extract]**Financials [extract]****Notes to the consolidated financial statements [extract]****22. Capital and financial risk management [extract]****Risk management strategy of hedge relationships**

The risk strategies of the designated cash flow, fair value, and net investment hedges reflect the above market risk strategies.

The objective of the cash flow hedges is principally to convert foreign currency denominated fixed rate borrowings in US dollar, pound sterling, Australian dollar, Swiss franc, Hong Kong dollar, Japanese yen, Norwegian krona and US dollar floating rate borrowings into euro fixed rate borrowings and hedge the foreign exchange spot rate and interest rate risk. There are also cash flow hedges of certain subsidiary expenditure not denominated in functional currency of the entity, to hedge foreign exchange spot risk. Derivative financial instruments designated in cash flow hedges are cross-currency interest rate swaps and foreign exchange swaps and forwards. The swap maturity dates and liquidity profiles of the nominal cash flows match those of the underlying borrowings and exposures.

The objective of the net investment hedges is to hedge foreign exchange risk in foreign operations. Derivative financial instruments designated in net investment hedges are cross-currency interest rate swaps and foreign exchange swaps. The hedging instruments are rolled on an ongoing basis as determined by the nature of the business.

Hedge effectiveness is determined at the inception of the hedge relationship and through periodic prospective effectiveness assessments to ensure that an economic relationship exists between the hedged item and hedging instrument.

For hedges of foreign currency denominated borrowings and investments, the Group uses a combination of cross-currency and foreign exchange swaps to hedge its exposure to foreign exchange risk and interest rate risk and enters into hedge relationships where the critical terms of the hedging instrument match with the terms of the hedged item. Therefore the Group expects a highly effective hedging relationship with the swap contracts and the value of the corresponding hedged items to change systematically in the opposite direction in response to movements in the underlying exchange rates and interest rates. The Group therefore performs a qualitative assessment of effectiveness. If changes in circumstances affect the terms of the hedged item such that the critical terms no longer match with the critical terms of the hedging instrument, the Group uses the hypothetical derivative method to assess effectiveness.

Hedge ineffectiveness may occur due to:

- a) The fair value of the hedging instrument on the hedge relationship designation date if the fair value is not nil;
- b) Changes in the contractual terms or timing of the payments on the hedged item; and
- c) A change in the credit risk of the Group or the counterparty with the hedging instrument.

The hedge ratio for each designation will be established by comparing the quantity of the hedging instrument and the quantity of the hedged item to determine their relative weighting; for all of the Group's existing hedge relationships the hedge ratio has been determined as 1:1.

The fair values of the derivative financial instruments are calculated by discounting the future cash flows to net present values using appropriate market rates and foreign currency rates prevailing at 31 March. The valuation basis is level 2 of the fair value hierarchy. This classification comprises items where fair value is determined from inputs other than quoted prices that are observable for the asset and liability, either directly or indirectly. Derivative financial assets and liabilities are included within trade and other receivables and trade and other payables in the statement of financial position.

The following table represents the carrying values and nominal amounts of derivatives in a continued hedge relationship as at 31 March.

	Nominal amounts €m	Carrying value assets €m	Carrying value liabilities €m	Other comprehensive income			Closing balance 31 March 2024¹ €m	Weighted average		
				Opening balance 1 April 2023 €m	(Gain)/ Loss deferred to OCI €m	Gain/(Loss) recycled to financing costs €m		Maturity year	FX rate	Euro interest rate %
At 31 March 2024										
Cash flow hedges - foreign currency risk²										
Cross-currency and foreign exchange swaps:										
- US dollar bonds	16,756	2,689	188	(2,709)	1,775	124	(810)	2039	1.18	3.29
- Australian dollar bonds	288	—	2	(21)	14	(6)	(13)	2027	1.56	1.57
- Swiss franc bonds	624	80	—	(3)	(22)	15	(10)	2026	1.08	1.57
- Pound sterling bonds	4,771	45	362	(37)	244	126	333	2043	0.86	4.05
- Hong Kong dollar bonds	233	20	—	(5)	2	3	—	2028	9.08	1.92
- Japanese yen bonds	78	—	11	(12)	15	(9)	(6)	2037	128.53	2.47
- Norwegian krona bonds	241	—	47	(12)	13	(6)	(5)	2026	9.15	1.12
- Foreign exchange forwards³	287	—	42	(34)	(15)	7	(42)	2024	29.88	—
Cash flow hedges - foreign currency and interest rate risk²										
Cross currency swaps - US dollar bonds	—	—	—	(11)	11	—	—	—	—	—
Net investment hedge - foreign exchange risk⁴										
Cross currency and foreign exchange swaps - South African rand investment	1,505	176	—	952	(54)	—	898	2026	17.81	2.19
	24,783	3,010	652	(1,892)	1,983	254	345			

...

Notes:

- 1 Fair value movement deferred into other comprehensive income includes €251 million loss (2023: €383 million loss) and €10 million gain (2023: €17 million gain) of foreign currency basis outside the cash flow and net investment hedge relationships respectively.
- 2 For cash flow hedges, the movement in the hypothetical derivative (hedged item) mirrors that of the hedging instrument. Hedge ineffectiveness of the swaps designated in a cash flow hedge during the period was €67 million (2023: €nil).
- 3 Includes euro and US dollar forward contracts against Turkish lira to hedge foreign currency forecast expenditures in local markets. Notional amounts of €166 million (2023: €259 million) and \$130 million or €121 million equivalent (2023: \$134 million or €124 million equivalent) with weighted average exchange rates of 29.68 (2023: 18.36) and 30.15 (2023: 20.07) respectively to Turkish lira.
- 4 Hedge ineffectiveness of swaps designated in a net investment hedge during the period was €nil (2023: €nil).

The carrying value of bonds includes an additional €710 million loss (2023: €776 million loss) in relation to fair value of other bonds previously designated in fair value hedge relationships.

4.3.3.A Costs of hedging
